he regarded as the second constituent of the limestone or other mild alkali, drawing the conclusion that the true caustic alkalies must be simple bodies which become mild only by uniting with fixed air. This view, after some opposition, was soon universally received by chemists. Black also distinguished more clearly than had been done before the difference between lime and magnesia. The discovery of latent heat is also due to him. The celebrated physicist Cavendish (1731-1810) added greatly to chemical knowledge by his accurate experiments upon gases. He investigated hydrogen, and was led to consider it identical with phlogiston. According to him, when dilute sulphuric acid is added to metallic iron or zinc, inflammable air or phlogiston separates unchanged from its combination with the calx, while the latter unites with the acid. If concentrated sulphuric acid be used, the phlogiston is no longer set free as inflammable air, but combines with a portion of the acid, forming another gas which is not inflammable (sulphurous acid, already called phlogisticated sulphuric acid by Stahl). Cavendish's view of the identity of hydrogen and phlogiston was soon admitted by the supporters of the phlogiston theory, especially after it was found that calxes could be transformed to metals when heated in an atmosphere of hydrogen. The original idea of phlogiston was thus somewhat modified. With Stahl a dephlogisticated substance meant one which had been oxidized: thus, sulphuric acid was dephlogisticated sulphur; while at the end of the phlogiston period it meant as well a body which had been deprived of hydrogen: thus Cavendish and Priestley call oxygen dephlogisticated water. Cavendish also investigated carbonic acid and the quantitative composition of atmospheric air. The latter he proved to contain oxygen and nitrogen in the same proportions at all seasons of the year and in different localities. He investigated the changes caused in air by combustion, showing that carbonic acid is formed only when the combustible is of animal or vegetable origin. Synthetically, he ascertained the composition of nitric acid by passing a series of electric sparks through air; also that of water. This last was specially important, having been used with great effect by the opponents of the phlogiston theory. Although few men contributed more to the overthrow of this theory than Cavendish himself, yet he to the last remained true to its tenets, having explained all his discoveries in accordance with them. His reputation has suffered greatly from this, for the chemists who subsequently correctly explained his observations have shared with him the merit of them. One of the last and firmest defenders of phlogiston was Priestley (1733-1804). Having invented suitable apparatus, similar to the pneumatic trough of the present day, he was enabled to collect and observe the properties of all the more important gases, the number of his discoveries in this field being truly remarkable.

Most important among them was the preparation of oxygen from the red oxide of mercury by means of heat, although Priestley himself failed to appreciate the true value of his discovery. He, however, observed that this gas is given off by growing plants, whence he concluded that the latter thus replace the oxygen which has been removed from the air by combustion, &c., and that the two processes are in equilibrium with each other, the constant composition of air being thus maintained. Of equal importance for the development of the present system, though exerted in a different direction, were the labors of the Swedish chemists Bergman and Scheele. The method of analysis by the wet way introduced by Boyle had been but little followed till Bergman (1735-'84), carrying out the idea, established a complete series of reagents, and taught their use. He thus laid the foundation of the present system of inorganic analysis. He saw the advantage to be gained by causing each ingredient of a compound to unite with some other body with which it formed a combination of known constitution, capable of easy separation, rather than seek to isolate and determine it as such. Bergman analyzed a great number of substances, and investigated the composition of many salts. But although possessing such correct views, he was an indifferent analyst, not equal even to some of his contemporaries. His reputation was so great, however, that many years elapsed before any correction of his results was allowed, though many of them have been since proved erroneous. He made numerous important discoveries; correctly explained the difference between cast iron, wrought iron, and steel, as well as the composition of many salts previously misunderstood. His most important work was upon chemical attraction (affinity). Some idea of its magnitude may be given by stating the fact that he drew up tables of the affinity of 50 different substances for each other, arranging them in two series according to their behavior when treated respectively in the dry or wet way. An enumeration of the original observations and discoveries of Scheele (1742-'86) would fill a volume. His investigations in organic chemistry alone are sufficient to prove him one of the best analysts that ever lived. He separated all the more common organic acids from plants, and knew how to distinguish them when mixed with each other, having devised processes for their separation. Several acids of the animal economy did not escape him. He detected the presence of glycerine in the fats, separating it by means of oxide of lead, and prepared prussic acid from prussian blue. He also discovered molybdic and tungstic acids. Most fruitful was his research on the minerals of manganese, which, when the means at his disposal are considered, must be regarded as standing without parallel in the annals of chemistry. He discovered, first, the presence of a new metal (manganese); second, on add-

ing muriatic acid to the black oxide of manganese, on which he was experimenting, a peculiar gas (chlorine) was evolved, the properties of which he accurately described. It is worthy of remark that he named it dephlogisticated muriatic acid, and at that time phlogiston was synonymous with hydrogen, showing that he regarded it in the same light as chemists do now. Thirdly, the ore of manganese on which he operated happened to contain a quantity of baryta, which he separated, and, having studied its properties, recognized as a new and peculiar substance. In solutions of its salts he found a test for sulphuric acid, which has since been universally used. Equally able was his investigation of fluor spar; he found it to be a compound of lime with a peculiar acid, which destroyed his vessels so rapidly that he was unable to collect it. He investigated atmospheric air in its relations to combustion, finding that it contains two different gases, one of which, "empyrean air" (oxygen), is capable of supporting combustion and respiration, while the other, "vitiated air" (nitrogen), cannot maintain these processes. He proved that the metals, when burned to calxes, absorb empyrean air, while the calxes give it off when reduced to metals. He prepared oxygen at about the same time as Priestley, entirely independently, as admitted by Priestley himself, having obtained it from peroxide of manganese and from saltpetre as well as from the oxides of silver and mercury. The fact that the phlogiston theory had become inadequate to explain many points already known in chemistry, is more fully exhibited by Scheele than by any other chemist. He ostensibly believed in this theory, yet observation had taught him that oxygen is absorbed by metals during calcination and by combustibles when burning. To explain this, he conceived that oxygen is a compound of water with a certain light saline matter, in which compound but little phlogiston is contained. During combustion the phlogiston of the combustible unites with the saline matter of the oxygen, producing light and heat, while the residual product is a compound of the matter which had originally been combined with phlogiston in the combustible, with the water of the oxygen. This theory, it will be seen, differs most essentially from that of Stahl, who saw in combustion nothing but a separation of phlogiston, while Scheele regarded it as a mutual decomposition of the combustible and the substance supporting combustion, new compounds being produced.—These views clearly show the transition state of chemistry at that period. In general, the ideas which the several chemists attached to phlogiston toward the end of the 18th century were far from exhibiting the accordance which had previously existed. The main feature of the phlogiston theory consisted in regarding combustion as depending upon decomposition, while chemists have since learned that it arises from the formation of compounds. It however explained the analogies and mutual rela-

tions of numberless phenomena which had previously been known as mere isolated facts. It was the most rational theory of combustion, and of many analogous processes now referred to oxidation and reduction, which had been proposed. In a comparatively short time it led to a multitude of discoveries. By regarding bodies as composed of undecomposable elements, it established the view which has ever since been admitted. Indeed, the definition of chemistry given by Stahl, the art of decomposing compound bodies and of reproducing them, is entirely in accordance with the spirit of the present day. Far from lamenting the phlogiston theory as an error, it should be regarded as a necessary basis for the views of the present epoch. In order to obtain a correct knowledge of substances, it was essential that their properties and relations to one another should be first investigated qualitatively. In the accomplishment of this work lies the merit of the phlogiston period. The quantitative method of investigation which followed, and which is characteristic of the present epoch, was but a natural succession. In no instance, however, in the history of chemistry has the transition from one system to another been so abrupt as from phlogiston to anti-phlogiston. Rarely has the introduction of an entirely new doctrine been so completely dependent upon one individual as was that of the present system upon Lavoisier (1743-'94). He first caused the importance of the quantitative method of research to be recognized, having by its aid perceived that the increase of weight acquired by a given weight of metal, when oxidized, must disprove the whole theory of phlogiston. The mere fact of this increase of weight had long been known; even Stahl was familiar with it. He regarded it, however, as entirely unessential and dependent on accidental circumstances. His followers were of the same opinion. One or two chemists had indeed called attention to the fact that this increase of weight was caused by an absorption of gas, but they had not themselves perceived the true importance of their observation, and their explanations had remained unnoticed. When at length the more careful investigation of Lavoisier had clearly proved the fact that the oxidation of metals is accompanied by increase of weight, the most absurd propositions were resorted to by the supporters of phlogiston. Among them it is only necessary to instance the hypothesis that phlogiston possessed absolute levity, being a substance endowed with a peculiar repulsive force, tending to remove it from the earth instead of gravitating toward it like other substances; whence a body losing phlogiston must become heavier. Lavoisier not only exposed the error of supposing that the heavier metallic oxide could be an ingredient of a metal possessing less weight, but also framed a new theory in explanation of the facts, viz. : that in calcination, as in combustion generally, one of the ingredients of the atmosphere unites with the combustible in such

proportion that the products of combustion weigh exactly as much as the sum of the weight of the substance consumed plus the weight of the matter absorbed from the air. Still more important was his proof that wherever an increase of weight occurs combination must have taken place; that the weight of the product of such combination is equal to the sum of the weights of its ingredients, while diminution of weight is invariably owing to separation of ponderable matter. As an investigator Lavoisier stands preëminent. His precision of observation, ingenuity in devising apparatus, and his patience, are only equalled by the clearness of his conclusions and his masterly description of facts. His original experiment, showing that the increase of weight which a metal acquires when calcined is caused by its combination with a gas, deserves to be mentioned. A known quantity of metallic tin having been placed in a retort, the latter was sealed up and the whole weighed. Heat was then applied until the tin, having melted, was converted to a greater or less extent into a calx. On again observing the weight of the apparatus, it was found to have remained unchanged. But on opening the retort, air rushed in, and on again weighing an increase of weight was found to have occurred. This excess of weight showed how much air had entered the retort to replace what had been absorbed, and it was found that the weight of the tin had been increased by the same quantity. After the discovery of oxygen by Priestley, Lavoisier refined this experiment by using mercury in place of tin. Continuing his observations on oxygen, he found that carbonic acid is a compound of it and carbon, and explained the combustion of organic substances. He also studied the composition of sulphuric and other acids, seeking to multiply proof of his view that oxygen is the universal acidifying principle. Cavendish's discovery that hydrogen when burned forms water, afforded Lavoisier a clue for the explanation of the solution of metals in acids, which had previously been the weak point of his theory. He recognized at once that decomposition of water must take place, its hydrogen being set free, while the oxygen unites with the metal. He also prepared water synthetically, and analyzed it by passing its vapor over red-hot iron, with which the oxygen united while hydrogen was set free, thus fixing its composition beyond the possibility of doubt. Lavoisier distinguished among the chemical elements those which ought to be regarded as simple, their further decomposition being improbable, as light, heat, oxygen, hydrogen, and nitrogen. Others he considered not so much simple as undecomposed, their ingredients not yet being known. In this class he placed the alkalies, earths, and metals. The radicals of the acids he supposed to be simple; of these, sulphur, carbon, and phosphorus were known, while the radicals of boracic, muriatic, and hydrofluoric acids

were merely hypothetical. He also sought to analyze organic substances by converting them into carbonic acid and water, thus originating the method now used, the means of executing which have alone been changed. The views of Lavoisier were greatly advanced through the coöperation of his contemporaries and countrymen, Guyton de Morveau (1737-1816), Fourcroy (1755-1809), and Berthollet (1748-1822). With Guyton de Morveau the idea of a rational nomenclature originated, and by his efforts the system now used was produced. The naming of chemical substances had previously been governed by no rules whatsoever, the name given to a new compound depending entirely on the taste and humor of its discoverer. With few exceptions no name offered any clue to the chemical properties of the substance. Guyton de Morveau first attempted in 1782 to express an idea of the composition of a substance by its name. This met with violent opposition from all sides. Lavoisier, however, had keenly felt the want of a systematic nomenclature; he therefore accepted the proposition to combine his new theory with the new nomenclature. Associating himself with Guyton de Morveau, Berthollet, and Fourcroy, a system was produced so nearly perfect that it only recently experienced a change in spite of the immense development which the science has since undergone, and the discovery of many substances, the existence of which could not have been foreseen at the time of its formation. Berthollet was the first chemist of importance who adopted the views of Lavoisier. He afforded them most important aid by many admirable experiments and acute investigations. Although he manifested his own independence by refusing to admit that oxygen is the only acidifying principle, two acids, hydrosulphuric and hydrocyanic, which contain none, being already known, he was nevertheless led into error by Lavoisier's assumption that muriatic acid was composed of an unknown radical united with oxygen; conceiving that chlorine was composed of the same radical combined with more oxygen, while the acid which he discovered in chlorate of potash was supposed to contain this radical combined with a still greater quantity of oxygen. This error was not corrected until long afterward. Of the works of Berthollet, that upon affinity was of most importance for theoretical chemistry. While he admitted that all substances have really different degrees of affinity for each other, he sought to prove that what was commonly called affinity depended in great measure upon the relative quantity of the bodies acting on each other (force of mass); moreover, that the phenomena of decomposition attending such action depend essentially upon the physical properties of the compounds which are formed. Since affinity can act only through direct contact of the most minute particles of matter, a body may be removed from the field of chemical action

either by its insolubility (preponderating cohesion), or by its escape in the gaseous form (elasticity). According to him, there is no reason why two bodies cannot unite in all possible proportions to form chemical compounds, if their cohesion and elasticity, as well as those of the resulting compounds, are equal. The very thorough manner in which Berthollet explained all existing facts by means of this theory, combined with the strictness of his conclusions, caused it to receive at once universal attention. A few of his views have been indeed disproved, but as a whole it has since exerted a highly important influence on chemistry. The intimate dependence of the phenomena of decomposition upon the physical character of the resulting compounds, and the great influence which mass exerts in most reactions, have been universally recognized. Berthollet made several important researches. He determined the composition of ammonia, discovered fulminating mercury, and contributed much to the existing knowledge of prussic acid, chlorine, and hydrosulphuric acid. The technical applications of chemistry which he brought about were numerous and exceedingly important; preëminent among them is the use of chlorine in bleaching.—The political condition of France toward the close of the 18th century exerted a most decided influence upon the progress and direction of chemistry, especially in its application to the arts, and its diffusion as a branch of popular knowledge. Previous to this time, technical chemistry was nothing but a collection of empirical facts, uncared for by scientific men, and all improvements in the arts depending upon chemical processes were the result of accident. But when France, a country accustomed to purchase from other nations her most important munitions of war, was cut off from outside communication, and compelled to defend herself against all Europe, scientific men, and especially chemists, were called upon to point out the means of producing the materials of war on which the very existence of the nation depended. They were asked to bring forth in a day arts which in other countries had resulted from the experience of years. There was no time now for a repetition of the groping empiricism by means of which these arts had been created. Science has rarely answered practical questions so quickly and clearly. Not only were the requisite munitions soon prepared, but many arts were developed to an extent previously unknown. A knowledge of the sciences thus came to be considered of great importance for the welfare of the nation. As soon as law and order had been in a measure restored, new institutions for instruction were formed, to replace those which had been destroyed, in which the study of mathematics and of the physical sciences was made preëminent. This purely material direction has been thoroughly carried out in several of the most renowned schools of France. The influence which it has exerted in diffusing chemical knowledge is

incalculable. Since the latter has become a matter of popular education, the methods of teaching it have been made subjects of special study and have been vastly improved. The immense influence which chemistry now everywhere exerts upon arts and manufactures, and which is one of the characteristics, not only of the science itself, but of the civilization of the 19th century, may be traced directly back to the labors of Berthollet, Guyton, and their associates. In connection with these, Fourcroy deserves mention. He devised the plan of the system of instruction introduced into France by Napoleon, and did good service as a lecturer and writer.—Attention having been specially directed to quantitative analysis by Lavoisier and Bergman, many chemists now occupied themselves with it. Of these, Klaproth (1743–1817) in Germany, Vauquelin (1763–1829) in France, and Proust (died 1826) in Spain, exerted the most influence. Klaproth was the first German chemist who admitted the correctness of Lavoisier's views. He did much to diffuse them among his countrymen, in spite of the national feeling brought to bear against the "French system." But his chief merit is as an analyst. He first introduced the custom of publishing the results of quantitative analyses, as found directly by experiment. Any loss or excess had previously been distributed among the several ingredients, and such corrected values alone published, leaving no clue from which other chemists might judge of the accuracy of the statement. This led to numerous errors, many false notions of the composition of bodies having long been held on the authority of a single analyst. The utility of Klaproth's system of publishing details has been most clearly proved by the fact that many of his own analyses have coincided with corrections which it has since been found necessary to apply to the inferences he had himself drawn from them. Klaproth devised the more common methods of decomposing insoluble minerals, which are still used. He pointed out the influence which the gradual destruction of the utensils in which analyses are made exerts upon the results obtained, and called attention to the necessity of applying a correction on account of it. Many of the methods now used for separating bodies from each other have come down from him. He discovered the oxides of uranium, zirconium, cerium, and titanium, and made many other important observations. Vauquelin performed a great amount of analytical labor, especially in regard to minerals. With Klaproth he had widely extended the field of analysis. But although they were agreed that most bodies have a constant or nearly constant composition, they were silent when Berthollet advanced an opinion that the reverse is often the case. Berthollet admitted but few compounds of constant composition in one proportion. In most bodies he thought the constituents capable of uniting in any proportion between two limits. Thus, iron could unite

with oxygen in any proportion between protoxide and peroxide. This view did much mischief. Every false analysis supported itself, while it seemingly supported the theory, upon it, by admitting that the combining proportions of the ingredients were variable. Proust deservedly won great reputation by proving that these supposed intermediate compounds do not exist in so many varying proportions. He demonstrated that when two substances unite in several proportions, the compounds formed are but few and are separated from each other by intervals, never gradually shading into each other. He explained correctly the composition of red lead, of magnetic oxide of iron, &c. He pointed out the errors committed by previous investigators of the subject, and the necessity of not confounding chemical compounds with mechanical mixtures. His views were soon received as correct by chemists, in spite of the opposition of Berthollet. He also carefully studied several metals and hydrates of metallic oxides, distinguished grape from cane sugar, &c. Proust and his predecessors, in determining the composition of bodies, sought only to ascertain how much of each ingredient was contained in a constant weight, usually 100 parts of the compound, thus referring the weight of the ingredient to that of the compound. The science had thus been greatly advanced, but still more important discoveries were made when chemists began to consider the relations which the weights of the several ingredients of a body bear to each other, and to investigate how much of one substance is required to replace another in a compound. The idea of chemical equivalents thus arose, and it was soon recognized that chemical combinations take place not only in constant but also in simple relations of weight. Wenzel in 1777, and Richter in 1792, in Germany, were the first who endeavored to call attention to this subject. The former explained the fact that when two neutral salts mutually decompose each other, the resulting mixture is still neutral, by admitting that a quantity of either base sufficient to neutralize one acid could also neutralize the other acid. He moreover showed that the relative weight of two bases which neutralize the same quantity of acid remains constant, no matter what acid may be used. Arguing from Wenzel's law, Richter showed that, in accordance with it, the composition of all the neutral salts of one acid and of any one salt of any other acid having been ascertained by analysis, the composition of any other salt of this acid could be calculated. He also showed that numbers could be affixed to the acids and bases which would express the relation of weight in which they combine with each other to form neutral salts, and even constructed such tables of equivalents. The views of both these chemists were neglected until the publication of the atomic theory of Dalton (1766–1844) recalled the attention of chemists to them, when they exerted no inconsiderable influence in establishing Dalton's doctrine. This last was much more extended

than the views of either of the chemists just mentioned. Having observed that when a determined quantity of any substance united with different quantities of a second substance, the quantities of the latter always bore a simple relation of weight to each other, Dalton was led to the formation of his atomic theory. He regarded the elements as composed of homogeneous atoms, the weights of which are different for each different element. An atom of one element can unite with one or more atoms of another element, the weight of the atom of the compound formed being the sum of the weights of its component atoms. He determined the relative weights of these atoms for the different elements, as expressed by the relative weights in which they unite to form compounds. Although the term atom used by Dalton expresses nothing more in a chemical sense than Richter's word equivalent, there was a tangibility in the former which caused the view to be more readily accepted. Moreover, Dalton's discovery of the law of multiple proportions, and that the atomic weight of compounds is the sum of the atomic weights of their ingredients, made the subject so complete that it could no longer be neglected. It was at once admitted into the science, and gave rise to the views concerning the quantitative composition of bodies which now exist. Besides the atomic theory, chemistry owes much to Dalton for his investigations of the expansion of gases, evaporation, and the relations of mixed gases, elasticity of steam, &c. Wollaston (1766-1828) did much to diffuse and extend Dalton's theory. His "scale of chemical equivalents" especially aided in this result. As an exact analyst also, he was deservedly celebrated. Most important in connection with Dalton's doctrine was the discovery by Gay-Lussac (1778-1850) of the law of combining volumes, in accordance with which gases unite with each other. In conjunction with Humboldt he first observed that one volume of oxygen unites with two volumes of hydrogen to form water. Extending his researches, he found that other gases unite in equally simple proportions, and that the volume of the resulting compound, if gaseous, bears a simple relation to the sum of the volumes of its ingredients. This proved conclusively that chemical compounds are formed only in a few fixed and definite proportions, according as it did with Proust's researches upon the composition of solid bodies. It was soon perceived that, the specific gravity of a gas being known, its atomic weight might be readily calculated, whence the determination of the density of gases became at once important. Of the many valuable investigations conducted by Gay-Lussac, those upon the expansion of gases by heat, density of vapors, for the determination of which he devised an apparatus, expansion of liquids, evaporation, sulphur acids, chlorine compounds, and iodine may be mentioned. His researches in organic chemistry were also very important. He first pursued the method of research which has since exerted

so great an influence upon the development of chemistry. The investigation of the cyanogen compounds and isolation of cyanogen, a compound of nitrogen and carbon, yet closely resembling in its properties the element chlorine, gave rise to the idea of organic radicals, and formed the starting point to which the present method of regarding organic bodies directly refers. He first devised an apparatus for the ultimate analysis of organic substances which produced useful results, infinitely superior to any previously obtained, and furnished a basis for improvement. He also introduced the system of determining the specific gravity of the vapors of substances to control analyses. Many of his applications of chemistry to the arts were of great importance; among them are the methods of assaying silver by the wet way, of alkalimetry, of chlorimetry, of assaying gunpowder, &c., still in use.—Simultaneously with the investigations upon the atomic weights and atomic volumes, which occupied chemists after the discoveries of Dalton and Gay-Lussac, another subject of great importance in its bearings upon the doctrine of affinity, and which produced most striking results when applied to the study of certain individual substances, was brought forward. This was the investigation of the connection between galvanism and the phenomena of affinity. When Berzelius and Hisinger began to study this subject in 1803, it had already been noticed that water could be decomposed by the galvanic current. They verified this experiment, and moreover showed that salts could be decomposed by the same means; while an electrical opposition between acids and bases was indicated by the fact that under all circumstances of decomposition acids were set free at the positive pole, bases at the negative pole, of the voltaic pile. The subject rested somewhat obscure, however, until cleared up by Sir Humphry Davy (1778-1829), most of whose labors were devoted to electro-chemistry. He first showed by a most admirable research that pure water when decomposed by galvanism produces only hydrogen and oxygen; that the acids (nitric and muriatic) and bases (ammonia and soda) obtained by previous experimenters had been produced either from air contained in the water or from the action of the galvanic current upon the vessels used in the operation. Studying this last action more carefully, he eventually succeeded in separating metals from the fixed alkalies, potash and soda, and proved these last to be metallic oxides. Small as were the quantities of metal thus obtained, he described their properties with surprising accuracy. He afterward proved that the alkaline earths are similarly constituted, and inferred from analogy that the earths are of the same nature; the correctness of which opinion has since been fully proved. Having studied the chlorine compounds, he was led to regard chlorine as an element, and disproved Berthollet's view of its composition, which had hith-

erto been universally received. This gave rise to the first modification of any importance which Lavoisier's system suffered. Oxygen could no longer be regarded as the sole acidifying principle. The idea of hydrogen acids was introduced, and substances which contain no oxygen admitted to be salts. Of the many other researches conducted by Davy, that upon flame and combustion, which led to the discovery of the safety lamp, was especially valuable. His electrical theory has been since modified, but, like most of his work, has been of immense importance to the science. The value of his discovery of the metals of the alkalis was not limited to a theoretical bearing alone. From the enormous affinity for oxygen which they possess, a means was furnished far stronger than any previously known of decomposing other bodies. They did not obtain their full importance as reagents, however, until a process of manufacture was devised by Gay-Lussac and Thénard, by which they were obtained in comparatively large quantities. By them the chemists last mentioned were led at once to the discovery of boron, of hydrofluoric acid, of fluoride of boron, &c. Since then they have been the means of many discoveries. As an investigator and diffuser of chemical knowledge, as well as by his systematic classifications, Thénard (1777-1857) was of great service to the science. His division of the metals into groups, according to their behavior at different temperatures in presence of water, has been quite generally followed. Among his important discoveries may be mentioned that of the peroxide and of the persulphide of hydrogen.—No one chemist since Lavoisier has exerted an influence comparable with that of Berzelius (1779-1848). In him were united all the different impulses which have advanced the science since the beginning of the present epoch. The fruit of his labors is scattered throughout the entire domain of the science. Hardly a substance exists to the knowledge of which he has not in some way contributed. A direct descendant of the school of his countryman Bergman, he was especially renowned as an analyst. No chemist has determined by direct experiment the composition of a greater number of substances. No one has exerted a greater influence in extending the field of analytical chemistry. The use of hydrofluoric acid in decomposing minerals, and of chlorine in the analysis of minerals containing metals capable of forming volatile chlorides, originated with him. Of his manifold and always admirable researches may be mentioned those upon the organic acids; upon selenium, which he discovered; upon the alkaline sulphides, in which the theory of sulphur salts, analogous to those of oxygen, was brought forward; upon the fluorine compounds; upon platinum and the metals occurring with it; upon tellurium; upon meteorites, and upon the silicates. He first isolated several substances, as silicon, zircon, tantalum, &c. The remarkable amal-

gam which mercury forms with what is supposed to be ammonium was first obtained by him in conjunction with Hisinger. One of the principal services he rendered was in developing the present theory of the science. Before Dalton's views had become generally known, Berzelius had perceived the importance of Richter's tables of the combining equivalents of acids and alkalis, and had carried out an extended investigation of the composition of salts to ascertain if they were true. The results obtained convinced him at once of the correctness of Dalton's generalization, which soon afterward came to his knowledge. He continued his researches, and worked out most fully the details of the subject. Among other things, he thus discovered the simple relation which the oxygen of the acid bears to the oxygen of the base in neutral salts. He also endeavored to ascertain with the greatest possible exactitude the relations of weight in which the different elements unite to form compounds. His acuteness in selecting the materials best suited for his experiments, and the precision with which their quantitative analysis was conducted, have never been surpassed. He did not limit himself to prove these equivalent weights for only a few substances. By far the greater number of the elements were investigated by him, and a large proportion of the equivalent numbers still in use are his. Corrections have been made only by those experimenters who have been able to procure purer materials; as an accurate analyst, Berzelius has never been surpassed. He first demonstrated that organic bodies combine according to the equivalent weights of their ingredients, and introduced the method of analyzing their compounds with inorganic bodies of known equivalent weight as a means of arriving at their equivalent. He maintained most persistently the view that organic substances form combinations analogous to those of inorganic bodies, and that they ought to be explained in accordance with what is known of the latter, having steadfastly opposed the innovations on this doctrine brought forward by other chemists. He made, however, numerous accurate analyses of organic substances, and chemistry owes to him the theories of copulate acids and of organic radicals. The latter, in accordance with which a substance may be composed of two or more elements, and yet be capable of entering into combination with elementary bodies as if it were itself elementary—in a word, play the part of an element—has since exerted a most important influence upon the development of the science. The admirable system of chemical symbols now in use also originated with Berzelius.—Following in the footsteps of Davy, Faraday (1791-1867) was most fortunate in developing the relations of electricity to chemistry. He widely extended the idea suggested by Davy that electricity and chemical affinity are only different expressions of one and the same force. All his experiments tended to support this view. Although most of his re-

searches fall more properly within the province of physics, they are nevertheless of the greatest interest in their chemical bearings. Preëminent in this respect are his works upon the liquefaction of gases, and upon certain compounds of hydrogen and carbon, which last was one of the starting points of the doctrine of isomerism, also upon the compounds of carbon and chlorine, and of ammonia and metallic chlorides. Working like Faraday in the domain of both physics and chemistry, Mitscherlich of Berlin (1794–1863) exerted a great influence on the present condition of the science by his discovery of the law of isomorphism, in accordance with which certain groups of substances exist, any one member of which can be replaced by any other member or set of members in equivalent proportion in its compounds, without changing the crystalline form of the latter to any material extent; and of dimorphism, the power possessed by some substances of crystallizing in two distinct systems not reducible to the same primary form. Following as did these discoveries upon those of Faraday, and that of the French physicists, Dulong and Petit, of the relation between the specific heats and equivalent weights of substances, it tended greatly to call the attention of chemists to the physical relations of bodies. A physico-chemical school has thus been founded, to which several of the leading chemists of the present day belong. The discoveries of Mitscherlich, the details of which he worked out by a series of most laborious researches, were soon brought to bear with advantage upon the classification of the elements, while that of minerals underwent an entire reform.—The theory of compound radicals proposed by Berzelius was again made specially prominent by the publication (in 1832) of a memoir, the joint production of Liebig (1803–73) and Wöhler (born 1800), upon the benzoyl series. Although Berzelius refused to admit the generalization made by these chemists, and disbelieved in the existence of radicals which like benzoyl contain oxygen, an interest was nevertheless excited, which greatly contributed to the advancement of organic chemistry. The ethyl theory quickly followed, and was adopted by most German and English chemists. These results mark an era in the history of modern chemistry. A throng of pupils immediately gathered about Liebig. No other chemist has ever had control over an amount of talent equal to that of the students who for years crowded his laboratory at Giessen. Through them he exerted an incalculable influence upon the present position of the science, while by his popular writings he did much to diffuse chemical knowledge among the masses. Of the special labors of Liebig may be mentioned his efforts to determine what substances should be regarded as radicals, and to classify all known organic bodies in accordance with them; also his important improvements in the methods of analyzing organic substances. Besides the

investigation of the oil of bitter almonds, which led to the discovery of the existence of benzoyl, his most important researches were made in conjunction with Wöhler; for example, those upon cyanogen compounds and the derivatives of uric acid, by which an immense number of new compounds were discovered. Wöhler has also independently brought to light many new facts, not only in organic but also in inorganic chemistry; for example, his investigation of the compounds of tungsten, the preparation of aluminum and of glucinum, and, in conjunction with H. Deville, of silicon and boron. His method of preparing urea (1828) from inorganic substances was the first and for years the only example of the power of chemists to form organic compounds from their elements. All organic substances previously obtained had been either derived directly from plants or animals, or had been products of the decomposition of substances thus obtained; it had indeed been doubted if any others could ever be prepared.—The labors of the recent French chemists have aided perhaps more than any others in elevating the science to its present position. Although seemingly standing for years in direct opposition to those of the German school, the systems of both have at length been harmoniously combined. Dumas of Paris first discovered, by his research upon the action of chlorine on acetic acid, that the three equivalents of hydrogen contained in the latter can be replaced by as many equivalents of chlorine, while the acetic acid retains most of its characteristic properties. Upon this and similar observations he founded his theory of substitutions, according to which hydrogen and some other ingredients of compounds may be replaced, equivalent for equivalent, by some other element or group of elements, while the properties of the original substance are usually not essentially changed. Few theories have been more bitterly opposed than this, but the facts are now universally admitted. The investigation of the substitutions which can be produced in organic compounds has been for several years a favorite study with chemists. Of late the means of bringing them about, and of reproducing the primary substance by replacing the elements originally removed, have been greatly increased and have led to many fine discoveries. Numberless researches upon organic substances have been conducted by Dumas with very important results. His determinations of the specific gravity of many vapors were of great value, the ingenious apparatus which he devised for this purpose having since been almost universally used. Determinations of the specific gravity of gases made in conjunction with Boussingault were also valuable. Among his most important investigations are those upon the amidogen compounds, ethers, volatile oils, and especially upon wood spirit, made in conjunction with Peligot, by which its resemblance to alcohol was shown—an analogy carried yet further by Balard's discovery of

amyl alcohol, which suggested the idea that the term alcohol must be regarded not merely in a specific but in a generic sense. Similar analogies were soon observed among other organic compounds, and it gradually became evident that very many organic substances could be classified together in homologous series, the composition of each member of which differs from that of the others, either by a certain number of equivalents of carbon and hydrogen, or by some simple multiple of this number; while the chemical properties of the several members of the series are entirely analogous, differing only in degree in direct proportion to the amount of carbon and hydrogen which they contain; whence, the general properties and relations of any one member of a series being known, those of any other of its members may be directly inferred. Remarkable relations between the physical properties of the different members of the same homologous series have also been noticed. Thus, H. Kopp has observed that the point at which the several members of a series boil increases about 19° centigrade for every two equivalents of carbon (old value) plus two of hydrogen which they contain more than the first member of the series. It is admitted by Kopp that the double atom of carbon elevates the boiling point 29° C., while the double atom of hydrogen diminishes it 10° C. The fusing point also of the members of several series presents analogous relations, while Kopp has shown by a number of most important investigations upon atomic or specific volumes (by which terms are understood the relative spaces occupied by the atoms or equivalents of bodies, being the quotients obtained by dividing their equivalent weights by their specific gravities), that the atomic volumes of many homologous compounds differ from each other by a constant quantity, proportional to the number of double atoms of carbon and hydrogen which they contain. The credit of the first clear perception of this wonderful system of homology is due to Gerhardt (1816-56). No system has done more to advance organic chemistry than this, while no one of his contemporaries has surpassed its gifted and laborious author. Of the chemists who especially devoted themselves to the advancement of the doctrine of substitution, no one can be compared with Laurent (1807-53). Denouncing compound radicals as purely hypothetical bodies, he endeavored to substitute for them his own theoretical nuclei. In itself this theory has exerted comparatively little influence. In the hands of Laurent, however, it led to the discovery of an immense number of new compounds, the very naming of which required that a special nomenclature should be framed. Few works of recent times have displayed greater originality than his *Méthode de chimie*. The comparative harmony now existing among chemists in their views regarding organic substances was in great measure brought about

by the investigations of the compound ammonias and ammoniums by Wurtz of Paris and Hofmann of London. Kolbe of Marburg and Frankland of Manchester had indeed isolated bodies of the same composition as methyl, ethyl, and other radicals, but their properties were less active than chemists had expected, and their identity with the true radicals was not at once admitted. The question was, however, settled by Hofmann's discovery that one or all of the equivalents of hydrogen in ammonia may be replaced by an equal number of equivalents of one radical possessing basic properties, like ethyl or methyl, or by several such radicals, so that four different radicals may be present in one equivalent of ammonium. Chemists were now forced to admit that the radicals entered into combination precisely as if they were elements, replacing hydrogen equivalent for equivalent. In like manner Gerhardt demonstrated that one or more of the three equivalents of hydrogen in ammonia may be replaced by a compound radical containing oxygen, as benzoyl; thus proving the correctness of the original benzoyl theory, which had suffered so many attacks. The extension given by these researches to the idea attaching to the term ammonia was immense. It became at once generic, including innumerable bodies, all possessing to a greater or less extent the characteristic properties of the original ammonia. Among the most interesting types of organic compounds are those in which two bodies of analogous nature are united together in such a manner that the properties of the compound resemble in kind those of one of its ingredients, the original properties of the latter being modified only in degree. Such compounds are called copulate or conjugate, and may be either acids, bases, or radicals. Many of the copulate acids were studied by Berzelius and his immediate followers, while the conjugate radicals have been especially investigated by Frankland, Löwig of Breslau, and others, among whom Prof. Wolcott Gibbs of New York and Dr. F. A. Genth of Philadelphia deserve special mention. The first investigation of this subject, and one of the finest in the records of chemical science, was that by Bunsen of Heidelberg on kakodyl, a radical composed of two equivalents of methyl united with one of arsenic. Of deep interest is the success which has recently attended attempts to prepare organic compounds by combining others of more simple composition. For a long time urea was the only compound which could be thus prepared, but within the last few years many such have been obtained. In this department, the experiments of Berthelot of Paris are most important. By heating carbonic oxide gas with hydrate of potash in a sealed vessel, he has obtained formiate of potash, from which formic acid may be readily prepared in a free state. By agitating olefiant gas (one of the components of ordinary coal gas) with oil of vitriol, a compound is formed from which, on addition

of water and distillation, alcohol is obtained. By analogous processes, any of the homologues of olefiant gas being substituted for it, the corresponding alcohols may be prepared. More than half a century ago Chevreul by a classical research proved that the fats are composed of various acids united with a peculiar sweet base, called glycerine. Subsequently Berthelot succeeded not only in recombining the fat acids with glycerine, thus forming the original fats, but also caused all the more common mineral and organic acids to unite with glycerine in a manner precisely analogous. Moreover, by substituting for glycerine any of the various species of sugar, similar combinations have been obtained with the fatty and other acids. The indefinite extension which has thus been given to the chemical idea of the fats is a good example of the spirit of generalization now greatly in vogue.—The comparatively immense development which the study of organic compounds has taken of late years has at length brought chemical science to such a position that a new epoch seems not remote. The laws by which the chemical relations of inorganic compounds have hitherto been so well explained, fail in many cases when applied to organic substances. The domain of organic chemistry has become so vast that it will soon assert its right to control the whole science. Several chemists have called attention to the apparent necessity of such reformation. It is acknowledged on all sides that the artificial division of chemistry into organic and inorganic, which has been admitted for some years, is entirely arbitrary, and in many respects unfortunate. That the science shall once more be consolidated is earnestly desired. The doctrine of substitution has already cleared up many matters in inorganic chemistry which had hitherto been inexplicable; while the question of doubling the equivalent weights of several of the elements in order to bring them into accordance with their combining volumes and certain other of their properties is still open. The extraordinary analogy between homologous groups of organic compounds and certain small groups of the elements, as chlorine, bromine, and iodine, has been remarked by several chemists. It has been generalized by Prof. J. P. Cooke of Cambridge, Mass., who has shown that not only isolated triads, but all the elements, may be brought into such homologous series, expressed like those of organic compounds by the general formula $a + nb$. The properties of the members of these series vary in degree in a regular manner according to their position, as in the series of organic bodies. Dumas criticised and in a measure modified Cooke's classification, while acknowledging its merit. The bearing of this subject upon the relations of compound radicals to the so-called elements cannot fail to strike every observer; the difference between them consisting simply in the ability of chemists to separate the former into several ingredients, while the latter are ele-

mentary only because they cannot as yet be thus decomposed.—Without occupying themselves with the investigation of a problem, the transmutation of metals, to the solution of which their science in its present condition offers no clue, chemists have ceased to ridicule the aspirations of the alchemists, although they will always condemn the venal spirit which actuated them. The possibility of effecting such transmutation has of late, however, been more strongly suggested by the discovery of several remarkable examples of allotropism, a term employed to signify that the same body may exist under two or more different conditions, possessing distinct physical and chemical properties. The fact that bodies so entirely unlike in their properties as the diamond, graphite, and charcoal are, chemically speaking, identical, standing as it did for a long time an almost isolated example, excited comparatively little attention. Nor was much notice taken of the different states of sulphur, and of other bodies the allotropism of which was less clearly apparent. But a deep interest was awakened by the discovery of ozone (allotropic oxygen) by Schönbein of Basel, and especially of red phosphorus by Schrötter of Vienna, bodies as unlike ordinary oxygen and phosphorus as can be conceived in every respect but their combining equivalents and reconvertibility into each other. The observation that the elements boron and silicon are, like carbon, susceptible of three modifications, strengthened this feeling. These discoveries recalled attention to the fact that several of the metallic elements have identical equivalent weights, as cobalt and nickel, platinum and iridium, &c.; the question naturally arising whether they may not be allotropic modifications of one and the same substance, especially as such modifications of several substances preserve their peculiarities even when combined in similar quantities with other bodies; for example, the compounds of the red and green varieties of the sesquioxide of chromium. Even the idea attached to the term element has been somewhat modified. At one time it was regarded as expressing not only a certain relative weight of a simple substance, but this substance was supposed to possess constant properties, which were as indestructible as the element itself. Instead of this view, which is at present untenable, the old idea of essence has been in a measure restored.—It would be of course impossible to enumerate here all the valuable labors which have recently been performed by chemists. Those of H. Rose (1795–1864) in developing inorganic analysis; of Regnault, Bunsen, Kopp, and Magnus (1802–'70) in investigating the physical laws connected with chemistry, and of the first two of these chemists in perfecting the processes of gas analysis; of Rammelsberg, Pasteur, Pelouze, Redtenbacher, Malaguti, Williamson, Heintz, Rochleder, Städeler, Strecker, Cahours, Anderson, Kolbe,

Draper, Wurtz, Kekulé, Fresenius, and a host of others, in addition to those who have previously been alluded to, in the field of organic chemistry, deserve special mention. The discovery of the anhydrous organic acids by Gerhardt may here be noticed, as well as H. Deville's process for preparing aluminum and sodium on the large scale, which promises to exert an influence in advancing chemical knowledge equal to that which resulted from the manufacture of potassium and sodium by Gay-Lussac and Thénard.—There is in modern times a general tendency to use the volumetric method of analysis, to employ the blowpipe for quantitative as well as qualitative analysis, and to apply the spectroscope to the detection of rare substances. The nomenclature of chemistry has undergone a remarkable change during the past few years. Old and familiar names have been dropped, and others more in accordance with the modern notions of the true composition of bodies have been substituted. The doctrines at first timidly advanced by a few chemists have gradually been accepted by a majority of scientific writers, and the whole language of the subject is now in a transition state. The equivalent value or combining capacity of an element is now measured by the number of atoms of hydrogen or other monatomic or univalent element with which the element in question can combine. Chlorine, which unites with one atom of hydrogen, is monatomic, monadic, or univalent. Oxygen, which combines with two atoms of hydrogen, is diatomic, dyadic, or bivalent. Nitrogen, which combines with three atoms of hydrogen, is triatomic, triadic, or trivalent. Carbon, which combines with four atoms of hydrogen, is tetratomic, tetradic, or quadrivalent. The elements are divided into two classes, one of odd, the other of even equivalence, the former distinguished as perisads, the latter as artiads; *e. g.*

Perissads... N, P, As, Sb, Au.
Artiads... O, S, Se, Te, Ba, Ca, Mg, Sn, Mo, W, &c.

The nomenclature of compounds has been adapted to the new order of things, and instead of saying carbonic acid, the compound is now called carbon dioxide or carbonic anhydride. In a work of this character it is preferable to retain the names of substances by which they have long been known, but the modern appellations will always be given.—The details of chemical science are treated in the articles AFFINITY, ATOMIC THEORY, ELEMENT, EQUIVALENT, ISOMERISM, NOMENCLATURE, SYMBOL, &c., and under the titles of the different animal, vegetable, and mineral substances.

CHEMNITZ, a city of Saxony, in the circle of Zwickau, at the foot of a northern offshoot of the Erzgebirge, on the river Chemnitz, 38 m. S. W. of Dresden, and 43 m. S. E. of Leipzig; pop. in 1871, 68,229. It is the most important manufacturing town in Saxony. In 1871 there were in the town 84 factories of woollen stuffs, 63 factories for stockings and mitts, and 25 for

cotton. There were also 19 iron founderies and 38 establishments for the manufacture of machines which are especially exported to Russia. Of the hosiery, gloves, embroideries, laces, and trimmings manufactured here, large quantities are shipped to America, Africa, China, and Japan. The exports to the United States in 1871 amounted to \$4,500,000; of which about \$2,440,000 were cotton hosiery, \$690,000 cotton and woollen gloves, \$1,025,000 embroideries, laces, and dress trimmings. It is connected by railway with Dresden and Leipsic. The first church was built here by the emperor Otho I. in 938. The town became a free imperial city under Rudolph of Hapsburg, and remained so during four centuries. The reformation was introduced by Henry the Pious in 1539. The thirty years' war ruined the town, but industry revived toward the end of the 17th century, when Chemnitz began to supply the German markets with cotton goods. In 1765 hosiery began to be made; in 1770 the first cloth manufactory was established; in 1775 the English quilt weaving was established here; the English hand loom was introduced in 1790; the Arkwright system of cotton manufacture in 1799. The continental blockade became a source of prosperity for Chemnitz, but subsequently, under the free trade system upheld by Saxony, while the surrounding countries maintained a protective tariff, the manufacturing interests of the town received a great blow, from which it only began slowly to revive in 1834, Saxony having joined the Zollverein. The growing trade with the United States gave an additional impetus to its industrial prosperity. The cotton goods, especially hosiery, compete successfully with those of England in excellence and cheapness, one factory, the largest in Saxony, having 18,600 spindles. The town is well built, containing some fine edifices, as St. James's church, with a lofty steeple and remarkable bell, the town house, and the cloth hall. There are five Protestant churches, and one Roman Catholic church; a Lutheran gymnasium, *Realschule*, technical school, and commercial school, attended by many pupils from abroad; a chamber of commerce and industry, United States consulate, and several banks. In 1872 there were published here two daily newspapers and three other periodicals.

CHEMNITZ, I. Martin (CHEMNITZ), a German Protestant reformer, born at Treuenbrietzen, Nov. 9, 1522, died in Brunswick, April 8, 1586. He studied at Magdeburg and Frankfurt-on-the-Oder, and went in 1544 to Wrietzen-on-the-Oder, where he saved from his earnings in teaching enough to maintain him for a year at the university. The year 1546 he spent at Wittenberg, under the instructions of Melancthon, by whose advice he gave his attention to mathematics and astronomy. The following year he went to Königsberg, and obtained a situation as rector of the cathedral school. His knowledge of astronomy attracted the atten-

tion of Duke Albert, who made him his librarian. Here he became interested in theology, and finally in 1553 obtained leave to return to Wittenberg. He now devoted himself entirely to the study of the reformed doctrines, and soon became an able expounder of the Protestant faith. From the lectures he delivered while at Wittenberg on Melancthon's *Loci Communes* originated his own celebrated theological work, *Loci Theologici*. In 1554 he accepted the pastoral charge of the church at Brunswick. Here he attacked the doctrines of the Jesuits in his work *Theologia Jesuitarum Præcipua Capita*. About this time a defence of the Jesuits and the council of Trent was published, which drew from him a reply entitled *Examen Concilii Tridentini*, a work regarded to this day by Protestants as an able vindication of the reformed faith. He next took up and defended Luther's views of the communion. He drew up a creed for the churches of lower Saxony, which was generally accepted. He was in favor of the *Formula Concordiæ*, and used his efforts successfully, in conjunction with Andreae, to induce the inhabitants of Swabia, Saxony, and Franconia to accept it as a rule of faith. He was highly esteemed by all parties for his moderation, and received frequent offers of place and emolument; but he invariably declined them, that he might devote himself to theology. He also began to write a work entitled *Harmonia Evangeliorum*, which was continued by Leyser and by Johann Gerhard, and which appeared in Hamburg in 1704. It was translated into German by Nicolai. **II. Philipp Bogislav von**, a German historian, grandson of the preceding, born at Stettin, May 9, 1605, died at Hallstad, Sweden, in 1678. Employed in the military service of Holland, and afterward of Sweden, he attracted the attention of Chancellor Oxenstiern, and at his recommendation Queen Christina appointed him royal councillor and historiographer. He published a history of the war carried on in Germany by the Swedes under Gustavus Adolphus (1648). He is the reputed author of a remarkable work, which appeared under the name of Hippolytus a Lapide, and was entitled *De Ratione Status in Imperio nostro Romano-Germanico*, &c. (2d ed., Freistadt, 1647). French translations of it appeared in 1712, and at the Hague in 1762.

CHEMNITZER, or **Khemnitzer**, **Ivan Ivanovitch**, a Russian fabulist, born in St. Petersburg in 1744, died in Smyrna, March 20, 1784. He was of German descent, began to study medicine, afterward served in the army, and after spending some time in mining employments accepted the office of consul general in Smyrna, where he fell into a state of melancholy from which he never recovered. His fables were published anonymously from 1778 to 1781, and under his name in 1799. Some of them are taken from Gellert and La Fontaine. The best editions are those published in Moscow by Ponomareff in 1836, and in St. Petersburg by Smirdin in 1847.

CHEMOSH (Heb. *Kemosh*), a national god of the Moabites and Ammonites, supposed by Jerome, but without foundation, to be the same as Baal Peor. Gesenius considers him a god of war, deriving his name from *kamash*, to subdue. King Solomon introduced the worship of Chemosh among the Israelites. He was worshipped, according to tradition, under the symbol of a black star; his worshippers went bareheaded, and used no garments sewn with the needle. His name constantly recurs in the inscription of King Mesha on the lately discovered stela, known as the Móabite stone. (See MOABITE STONE.)

CHEMUNG, a S. county of New York, bordering on Pennsylvania, bounded E. partly by Cayuta creek, and intersected by Tioga river; area, 513 sq. m.; pop. in 1870, 35,281. The Northern Central and the Erie railroads traverse the county, and the canal from Elmira to Seneca lake partly intersects it. The surface is uneven, and in some places rises into considerable mountains. The country near the river banks is level and alluvial, and these flats are in some places extensive and very fertile. The chief productions in 1870 were 162,434 bushels of wheat, 215,305 of Indian corn, 480,161 of oats, 116,152 of buckwheat, 138,573 of potatoes, 50,066 tons of hay, 1,203,401 lbs. of butter, 48,983 of wool, 475,905 of tobacco, and 33,933 of honey. There were 5,217 horses, 12,257 milch cows, 7,968 other cattle, 15,257 sheep, and 6,990 swine. There were 26 manufactories of carriages and wagons, 4 of boots and shoes, 1 of forged and rolled iron, 4 of tobacco and cigars, 4 of woollen goods, 17 flour mills, 9 tanneries, 32 saw mills, 2 manufactories of bricks, 4 of cheese, 1 of rectified petroleum, 2 of drugs and chemicals, 7 of furniture, 1 of hardware, 5 of iron castings, 3 of machinery, and 3 breweries. Capital, Elmira.

CHENANGO, a S. E. central county of New York; area, 624 sq. m.; pop. in 1870, 40,564. Unadilla river touches its E. boundary; the Chenango and the E. branch of the Susquehanna intersect it; and it is drained and supplied with water power by several smaller streams. The surface is elevated, and in some places broken and hilly. The soil is good, especially near the rivers. The Chenango canal, traversing the county, connects Binghamton with Utica. The Albany and Susquehanna railroad passes through the S. E. corner, and the New York and Oswego Midland, and the Delaware, Lackawanna, and Utica division of the western railroads traverse the county. The chief productions in 1870 were 19,418 bushels of wheat, 228,921 of Indian corn, 584,429 of oats, 398,045 of potatoes, 183,291 tons of hay, 280,114 lbs. of cheese, 5,319,814 of butter, 117,546 of wool, 397,570 of maple sugar, and 586,990 of hops. There were 10,389 horses, 51,294 milch cows, 17,168 other cattle, 26,472 sheep, and 9,521 swine. There were 37 manufactories of carriages and wagons, 37 of cheese, 1 of cotton goods, 14 flour mills, 13 tanneries,

36 saw mills, 4 manufactories of agricultural implements, 14 of furniture, 7 of pig iron and castings, 3 of machinery, 17 of saddlery and harness, 7 of woollen goods, and 2 breweries. Capital, Norwich.

CHENANGO RIVER rises in Oneida co., N. Y., flows S. S. W. through Madison and Chenango cos., and empties into the Susquehanna in Broome co., near the Pennsylvania border. Its whole length is about 90 m.

CHENAUB, Chenab, or Chinab (anc. *Acesines*), the largest of the five rivers of the Punjab, tributary of the Indus; total length about 750 m. The Chenaub rises about lat. 32° 48' N., lon. 77° 27' E., in Lahool, S. of Ladakh, and flows N. W. to the borders of Cashmere, and thence mainly S. W. A little below Aknoor it emerges upon the plain of the Punjab, from which point it is navigable for rafts. Still holding a S. W. course, it unites with the Jhylum, and about 50 m. below with the Ravee, and then with the Ghara, or lower Sutlej, from which point it loses its name, and the united stream is called the Punjnuud, which flows into the Indus just as it leaves the S. boundary of the Punjab. The water of the Chenaub is red, that of the Ghara pale, and these distinctive colors may be seen for some miles downward in the united stream, the red on the western, and the pale on the eastern side.

CHENAVARD, Paul, a French painter, born in Lyons, Dec. 9, 1808. Previous to the revolution of 1848 he was already known by his pictures of the "Trial of Louis XVI." and "Mirabeau answering the Marquis of Dreux-Brézé." He was now chosen to execute 50 cartoons for the French Pantheon, and selected for his subject the history of civilization from Genesis to the French revolution. Twenty of the cartoons were completed when, in 1853, the Pantheon was restored to the service of religion as the church of Ste. Geneviève. Three of them attracted much attention at the exhibition of 1853. He received the decoration of the legion of honor in 1853, and a medal of the first class at the universal exposition in 1855.

CHENDAREE, Chandairi, or Chunderee, a town and district of Malwa, in the territory of Gwalior, Hindostan, situated near the frontier of Bundelcund, 115 m. S. of Gwalior, and 280 m. S. S. E. of Delhi. The town is large, surrounded by hills and jungles, with which a few fertile tracts are interspersed. Its manufacturing importance, once considerable, has been destroyed by British importations, and its architectural beauty is in ruins; but even in its present decayed state it has many indications of ancient greatness. It has a strong fort, situated on a precipitous hill, connected with another hill by a narrow neck of land having a steep descent on each side. While Malwa remained an independent kingdom, Chendaree was the seat of powerful feudatory chieftains, one of whom, having revolted against the king, Mahmoud Khilji, was besieged in his capital for eight months. The

town afterward became subject to the sovereign of Delhi, from whom it was taken by the Rajpoots about 1526. Two years later it was seized by the Mogul chief Baber. It was annexed to Bundelcund, was taken about 1816 by Sindia's general Baptiste, passed into the hands of the Mahrattas, and became a haunt of robbers and freebooters. It was then taken under British protection, and finally in 1844 was assigned, with other lands, for the support of the force known as the Gwalior contingent. It was occupied by the sepoy rebels early in 1858. The first brigade of the central India field force was sent against it in March, and the fort was taken on the 17th. The fortifications were destroyed, but a month or two later the rebels again entered the town, to the number, it is supposed, of about 5,000, mostly from Bundelcund. They were driven out by Gen. Smith, May 25.

CHENEVIX, Richard, an Irish author and chemist, of French descent, born in 1774, died in Paris in April, 1830. Among his publications are "The Mantuan Rivals," a comedy, "Henry VII.," a historical tragedy, and an "Essay on National Character." He is chiefly known, however, as a writer on chemistry. His most important works are "Remarks on Chemical Nomenclature according to the System of the French Neologists" (1802), and "Observations on Mineralogical Systems," which first appeared in a French translation in the *Annales de Chimie*.

CHÉNIER. I. Louis de, a French historian, born at Montfort, Languedoc, in 1723, died in Paris, May 25, 1796. Established as a merchant at Constantinople, he was afterward employed there in the French embassy, and subsequently sent on a mission to Morocco, where he was successively consul general and chargé d'affaires. He published *Recherches historiques sur les Maures et l'empire de Maroc* (Paris, 1787), and *Histoire des révolutions de l'Empire Ottoman jusqu'à la mort du sultan Abdul-Hamed* (new ed., 1808). **II. André Marie de**, a French poet, son of the preceding, born in Constantinople, Oct. 29, 1762, guillotined in Paris, July 25, 1794. After completing his education, he entered the military service, but soon resigned his commission and repaired to Paris. In 1784 he travelled through Switzerland, Italy, and the archipelago, to his native city. In 1787 he was made secretary to the French embassy in London, and spent nearly three years in England. On returning to Paris he joined the moderate party, and expressed his disapprobation of the violent measures of the revolutionists, not only in his conversation, but in several articles marked by cutting irony and invective. The revolution of Aug. 10 closed for a time his political career, and he applied himself again to poetry. But when Louis XVI. was arraigned before the convention, Chénier assisted Malesherbes in his defence of the king, and on his condemnation he drew up an address for an appeal to the people. On the assassination of Marat by Charlotte Corday, he was among

the first to applaud the act, thus making himself still more obnoxious to the terrorists. While on a visit to Mme. de Pastoret at Passy, a commissary from the committee of public safety came to arrest that lady. Chénier interfered in her behalf, and was himself arrested and taken to the prison of St. Lazare. There he wrote some of his most bitter poems against the tyrants of the day; at the same time that he composed for the countess de Coigny, one of his fellow prisoners, *La jeune captive*, a poem which alone would have been sufficient to commend his name to posterity. On July 25 he was arraigned before the revolutionary tribunal, and sent forthwith to the guillotine. He preserved his self-possession to the last, suffering death with unflinching courage. An edition of his poems was published in 1820, and various editions have since appeared. The idyls *L'aneugle*, *La liberté*, and *Le jeune malade* are considered his masterpieces. **III. Marie Joseph**, a French poet, brother of the preceding, born in Constantinople, Aug. 28, 1764, died in Paris, Jan. 10, 1811. After leaving college he was for two years an officer; but as early as 1783 he left the military service and devoted himself to literature. His first attempts at tragedy were not successful; but in 1789 he produced *Charles IX.*, a play with marked republican tendencies, which hit the popular vein, and was received with great applause. *Henri VIII.* was performed in 1791, and was succeeded by *La mort de Calas*, both remarkable for purity of style, but above all for democratic aspirations. He also produced the tragedies of *Caius Gracchus*, *Timoléon*, and *Fénelon*, which were proscribed on account of their republican sentiments. He was the author of the *Chant du départ*, which next to the *Marseillaise* is the most celebrated lyric of the revolution. He was chosen to the national convention in 1792, but, although siding with the *montagne* party, he was the first to oppose revolutionary excesses. He was chosen president of the convention in 1795, and afterward became a member of the council of 500. The tragic end of his brother affected him deeply, notwithstanding their political differences. Discontinuing almost his contributions to the stage and his speeches on political subjects, he now confined his activity mainly to the subject of public education. In 1801 he published *Discours sur les progrès des connaissances en Europe, et de l'enseignement public en France*. From 1803 to 1806 he was inspector of public instruction, being at the same time a member of the tribunate. In 1806 and 1807 he delivered a series of historical lectures upon French literature. In 1808, Napoleon having requested the French institute to report upon the recent progress of French literature, the report was written by Chénier under the title of *Tableau historique de l'état et des progrès de la littérature française depuis 1789*, a work remarkable for extensive knowledge, soundness of criticism, and great impartiality. His last performance was another

report upon the decennial prizes. During all this time poetry had not been neglected; he had written several satirical or philosophical epistles, the style of which is at once fervid and classic; the two most remarkable among the number being one addressed to Voltaire, and another *Sur la calomnie*, in which he repelled the calumnies hurled against him in consequence of his brother's death. He has left also several tragedies; one of them, *Tibère*, is pronounced his masterpiece. His complete works were published in 8 vols. 8vo in 1823-'6, with notices by Daunou and Arnaut.

CHENONCEAUX, Castle of. See BLÉRÉ.

CHENOT, Claude Bernard Adrien, a French engineer, born at Bar-sur-Aube in 1803, died in 1855. He entered the mining school in Paris in 1820, after which he was attached to the secretaryship of the department of bridges and roads, and superintended the working of the mines in Auvergne. In 1832 he invented an apparatus for the manufacture of metallic sponges, and afterward obtained sponges from the earthy minerals, as aluminum and calcium, which he made to enter into other combinations, especially with steel, to which he thus gave remarkable properties. Matter in the sponge state, he thought, is the greatest power to which the chemist can have recourse, and he sought to found upon it a new system of metallurgy. He made many experiments for the purification of combustibles and metals.

CHEOPS, an ancient king of Egypt, who reigned several thousand years B. C. and built the first and largest pyramid. Diodorus calls him Chembes or Chemmis, but the name Cheops given to him by Herodotus has superseded all others, and is now universally applied to him and his pyramid. According to Herodotus, he was the first bad king of Egypt. He closed the temples and forbade the people to offer sacrifices, compelling them to labor in his service. He reigned 50 years, and was succeeded by his brother Cephren, who built the second pyramid. The Egyptians hated these kings as tyrants so much that even in the time of Herodotus they did not like to mention their names, but, as he says, "called the pyramids after Philiton, a shepherd who at that time fed his flocks about the place." What this passage means modern scholars have not been able to determine. The most plausible conjecture is that the Egyptians had forgotten who built the pyramids, and ignorantly ascribed them to the foreign conquerors and tyrants called shepherd kings, though it is certain that they were built long before the shepherd kings entered Egypt. Cheops has been identified by modern researches with the Suphis of Manetho (who ascribes to him a reign of 63 years) and the Shufu of the inscriptions; and his brother Suphis II. seems to have reigned conjointly with him and to have contributed to the building of the pyramid, in which they were both buried. The chamber in the great pyramid called the queen's chamber was in

reality that which contained the body of the second Shufu, who, surviving his brother, was considered his successor.

CHEPSTOW, a market town of Monmouthshire, England, on the Wye, and on the railway from Gloucester to Milford Haven, 12 m. S. of Monmouth; pop. in 1871, 6,770. It contains an ancient church, formerly belonging to the Benedictine priory, recently restored to its former splendor, a Catholic and several dissent-

CHERASCO, a town of Italy, in the province of Cuneo, situated on an elevation near the junction of the Stura and Tanaro rivers, 18 m. N. of Mondovi; pop. about 9,000. It contains a college, several palaces, conspicuous triumphal arches, and seven churches, of which that of the Madonna del Popolo is celebrated for its altar. Silk is manufactured, and there is a trade in grain and wine. Organic remains abound in the vicinity, and petrified wood is

Castle of Chepstow.

ing chapels, and a castle founded in the 11th century by William Fitzosborne, earl of Hereford, rebuilt in the 13th, and still a magnificent pile. On account of the narrowness of the channel here, the tide sometimes rises, it is said, 70 ft., frequently more than 50. The town possesses a large trade in timber, coals, millstones, and iron. There are no manufactures, but ship building is carried on to some extent.

CHER, a river of France, rises in the department of Creuse, flows N., N. W., and W., and after a course of 220 m., during which it describes a semicircle, joins the Loire near Tours. The canal of Berry runs parallel to it in the upper part. Its principal affluents are the Tardes, Arnon, and Sauldre. It is navigable 47 m. from the Loire.

CHER, a central département of France, formed of portions of the old provinces of Berry and Bourbonnais, and bordering on the departments of Loiret, Nièvre, Allier, Creuse, Indre, and Loir-et-Cher; area, 2,780 sq. m.; pop. in 1872, 335,392. It is bounded E. by the Loire and intersected by its tributary the Cher, and drained by several other streams. The surface is comparatively level. There are mines of iron, manganese, lead, and coal, and marble and other quarries. It is one of the most important industrial departments of France, having manufactories of iron, woollen, and linen, and of porcelain, glass, and other wares. The most important agricultural productions are wine, grain, cattle, and wool. The department is divided into the arrondissements of Bourges, St. Amand, and Sancerre. Capital, Bourges.

found in the adjoining hill of S. Bartolommeo. A treaty of peace was signed here in 1631, terminating the Mantuan war of succession between Austria and France. In April, 1796, after the battle of Mondovi, the French troops advanced upon Cherasco, which speedily surrendered, and the Sardinian commissioners concluded an armistice, preliminary to a treaty of peace with Napoleon. The French destroyed the ancient fortifications in 1801.

CHERBOURG (anc. *Coriallum* or *Cortallum*, afterward *Carusbur*), one of the

principal seaports and naval stations of France, in the department of La Manche, 185 m. W. N. W. of Paris, with which it is connected by railway; pop. in 1872, 37,357. It is situated on the N. shore of the peninsula of Cotentin, at the mouth of the Divette, in the centre of a bay, the extremities of which are formed by Cape Levi on the east and Cape La Hague on the west. The roadstead, in a bay at the N. extremity of a narrow promontory, has been formed by the construction of an immense breakwater upward of 2 m. long, running E. and W., partly across its mouth, and composed of two unequal arms, joined at an angle of 170°, with the opening toward the land. This stupendous work, commenced in 1784, was completed in 1854, at a cost of 67,300,000 francs. (See **BREAKWATER**.) The roadstead which it serves to defend has anchorage for 400 large vessels. At each end of the breakwater is an entrance to the harbor 1,000 yards wide. The commercial harbor is at the head of an inner bay at the S. end of the roads, near the mouth of the Divette, and consists of an outer basin communicating with the sea by a channel 656 yards long and 55 yards wide, bordered with long quays, and with an inner floating dock, closed by flood gates. The military port is distinct from this, and lies on the W. shore of the same recess, facing N. E. It comprises three large docks, viz.: an outer one, 984 ft. long and 754 ft. wide; another on the north, communicating with the former, and closed by lock gates; and a third on the west, larger than either of the others, through which it must be entered. All these have been exca-

vation from the solid rock. The first, the construction of which is due to Napoleon I., was inaugurated by the empress Maria Louisa in 1813; the second was commenced the same year; and the third, called the dock of Napoleon III., built of granite masonry, 1,377 ft. long and 600 ft. wide, was begun in 1836, and opened in the presence of the French emperor and empress, Aug. 7, 1858. Its cost was 16,000,000 francs. Brilliant fêtes and rejoicings preceded and followed the ceremony, and the occasion was selected for a visit to the works by the queen of England, for the inauguration of an equestrian statue of Napoleon I., and for the opening of the railway from Cherbourg to Paris. There are six smaller docks or building slips connected with the principal basins, and the dock of Napoleon III. has three of its sides grooved with slips for repairing vessels. These slips, seven in all, are furnished with flood gates, and may be used as dry docks. Sur-

bourg is ill built, but has fine promenades and a handsome theatre, and on the Place d'Armes is a monument commemorating the landing of the duke of Berry in 1814. It is the seat of many foreign consuls, of a maritime prefecture, of civil and marine courts; has a communal college, a public library, and a library connected with the navy. The chief exports are eggs, butter, and cattle. There are some sugar and salt refineries, and manufactures of chemicals, leather, lace, and hosiery. It is estimated that about one half of the population are employed in the navy yard.—As early as the 10th century Cherbourg was very much frequented as a port. When Edward III. of England landed at La Hogue in 1346, Cherbourg was among the first cities of Normandy conquered by the English. It changed hands several times, until it was finally secured to the French by Dunois in 1450. During the seven years' war the English effected a descent

Town and Harbor.

rounding the basins are workshops, smithies, timber yards, a ropery, furnaces, barracks, a powder magazine, and all the establishments necessary for a naval arsenal, the whole shut in by a strong line of fortifications extending from shore to shore. The town and harbor are defended by a series of formidable works commanding every avenue of approach. On the centre of the breakwater is a strong fort, and on each of its extremities is a battery crossing fire with similar works on the opposite points of land, or intervening islands. The shores of the bay and several rocky islands bristle with the guns of numerous forts, so placed as to sweep every part of the roadstead and harbor; while on the land side the town is surrounded by a double line of 14 star forts and redoubts; making a total of 24 regular works of defence, mounting over 3,000 guns of heavy calibre, which have been erected in different parts of this apparently impregnable position. Cher-

bourg is ill built, but has fine promenades and a handsome theatre, and on the Place d'Armes is a monument commemorating the landing of the duke of Berry in 1814. It is the seat of many foreign consuls, of a maritime prefecture, of civil and marine courts; has a communal college, a public library, and a library connected with the navy. The chief exports are eggs, butter, and cattle. There are some sugar and salt refineries, and manufactures of chemicals, leather, lace, and hosiery. It is estimated that about one half of the population are employed in the navy yard.—As early as the 10th century Cherbourg was very much frequented as a port. When Edward III. of England landed at La Hogue in 1346, Cherbourg was among the first cities of Normandy conquered by the English. It changed hands several times, until it was finally secured to the French by Dunois in 1450. During the seven years' war the English effected a descent on the coast, took the town, and destroyed all the naval and military works, docks, and arsenals, blowing them up, and burning the lock gates of the harbor with all the vessels in it. The project of creating at Cherbourg a harbor of refuge for war vessels was entertained by Louis XIV. as early as 1665, and Vauban was commissioned to draft the plans of a series of improvements and defences; but nothing was done till 1739, when quays and two moles were constructed. From that time the works were continued, with occasional interruptions, until their completion in 1865. Nearly \$100,000,000 are supposed to have been expended upon them. Violent storms have more than once destroyed the labor of years.—On June 19, 1864, the engagement between the Kearsarge and the confederate steamer Alabama took place off Cherbourg, 9 m. from the harbor, which resulted in the destruction of the Alabama. On Jan. 11, 1866, a violent storm stranded 22 vessels in the road, but caused no injury to the breakwater.

CHERBULIEZ. I. Antoine Élisée, a Swiss political economist, born in Geneva in 1797, died in Zürich, March 4, 1869. In 1833 he became professor of jurisprudence, and in 1837 of political economy, at the high school of Geneva. He took part in public affairs in the conservative interest till the revolution of 1848, when he went to Paris, where he continued to oppose revolutionists and socialists. He returned to Switzerland in 1853, and after teaching for

some time in Lausanne became professor of political economy in the national polytechnic institute in Zürich. Among his principal writings, besides many contributions to cyclopædias and periodicals, are *L'Utilitaire* (3 vols., Geneva, 1828-'30), and *Précis de la science économique* (2 vols., Paris, 1862).—His brother ANDRÉ (born in 1795) has also acquired literary reputation, as well as the younger brother JOËL (born in 1806, died in November, 1870). The three sisters, ADRIENNE (born in 1804), CAROLINE (born in 1800), and Mme. TOURTE-CHERBULIEZ (born in 1793, died in 1864), became likewise known by their literary activity, especially the last named, as a writer of popular tales and novels. **II.** Victor, a Swiss author, nephew of André, born about 1832. He has acquired celebrity by a work entitled *À propos d'un cheval, causeries athéniennes* (Geneva, 1860; 2d ed., 1864, under the title *Un cheval de Phidias*), and a series of novels (1863-'9, mostly first published in the *Revue des Deux Mondes*), the most brilliant of which are *Le comte Kostia* (1863) and *Paule Méré* (1864). Among his other works are *Le prince Vitale* (1864), *Le roman d'une honnête femme* (1866), *Prosper Randoce* (1867; English translation, 1868), *L'Aventure de Ladislav Bolski* (1869), and *L'Allemagne politique depuis la paix de Prague* (1870).

CHÉRI, Rose Marie Cizos, a French actress, born at Étampes, Oct. 27, 1824, died at Passy, Sept. 22, 1861. The daughter of an actor, she appeared on the stage in 1830, and was afterward greatly admired in the many cities she visited in company with her father. In 1842 she went to Paris, and appeared twice at the Gymnase theatre, but made so little impression that she was induced to accept an engagement at a salary of less than \$200 a year. She afterward produced a deep impression on the audience, and became a great favorite in Paris. Her salary was increased fourfold, and the most popular dramatists were anxious to have her perform in their plays. Her characteristics were a singular *nâveté* of expression blended with refined and graceful manners. She achieved her greatest triumphs in *Clarisse Harlowe* and *La naïve de St. Flour*, expressly written for her. She also portrayed with great success characters of a different kind in *Le fils de famille*, *Diane de Lys*, and *Le demi-monde*. On May 12, 1845, she married the manager of the Gymnase theatre, M. Lemoine-Montigny, but continued to appear upon the stage under her own name.

CHEROKEE, the name of six counties in the United States. **I.** The S. W. county of North Carolina, bounded N. E. by Graham county; area, 650 sq. m.; pop. in 1870, 8,080, of whom 301 were colored. It is intersected by Hiawassee river and its branches, and borders on Tennessee and Georgia. The surface is mountainous, Unaka or Smoky mountain in the N. W., and the Blue Ridge, near the S. E. border, being the principal ranges. The soil near the

streams is fertile. The chief productions in 1870 were 3,628 bushels of wheat, 8,830 of rye, 162,529 of Indian corn, 18,098 of oats, 10,702 of Irish and 8,588 of sweet potatoes, 560 tons of hay, 19,392 lbs. of tobacco, and 70 bales of cotton. There were 841 horses, 2,042 milch cows, 3,435 other cattle, 6,693 sheep, and 8,735 swine. Capital, Murphy. **II.** A N. W. county of Georgia; area, 620 sq. m.; pop. in 1870, 10,399, of whom 1,281 were colored. The soil is fertile, and the surface diversified by hills and fine rolling lands. In the N. E. part are quarries of excellent statuary marble; gold mines have been opened, and iron, copper, and titanium are also found. The Etowah, the principal river, is navigated by steamboats, and supplies good water power. The chief productions in 1870 were 59,064 bushels of wheat, 168,529 of Indian corn, 22,786 of oats, 11,911 of sweet potatoes, 53,797 lbs. of butter, 18,497 of tobacco, and 347 bales of cotton. There were 725 horses, 1,466 milch cows, 2,658 other cattle, 4,715 sheep, and 9,423 swine. Capital, Canton. **III.** A N. E. county of Alabama, bordering on Georgia; pop. in 1870, 11,132, of whom 1,480 were colored. The former area was 710 sq. m., but a portion has been taken to form Etowah county. The Coosa river, which bisects it, and the Chattooga, one of its affluents, are the principal streams. There are several mountain ranges, and extensive forests of pine oak, &c. The Selma, Rome, and Dalton railroad passes through the S. E. corner. The chief productions in 1870 were 68,530 bushels of wheat, 231,946 of Indian corn, 27,683 of oats, 24,675 of sweet potatoes, 1,807 bales of cotton, and 7,470 lbs. of tobacco. There were 1,406 horses, 772 mules and asses, 2,262 milch cows, 3,968 other cattle, 5,835 sheep, and 11,750 swine. There were 9 flour mills, 3 saw mills, and 1 manufactory of pig iron. Capital, Centre. **IV.** An E. county of Texas, bounded E. by the Angelina river, and W. by the Neches; area, 1,144 sq. m.; pop. in 1870, 11,079, of whom 3,283 were colored. It is well watered, and consists of prairies alternating with woodland, pine and oak being abundant. It is one of the best farming counties in the state. Iron ore is abundant. The chief productions in 1870 were 292,181 bushels of Indian corn, 30,230 of sweet potatoes, and 5,185 bales of cotton. There were 2,448 horses, 4,182 milch cows, 9,143 other cattle, 1,962 sheep, and 22,251 swine. There were an iron foundery, and manufactories of iron castings and machinery. Capital, Rusk. **V.** A N. W. county of Iowa, drained by Maple river, the Little Sioux, and the W. fork of the latter; area, about 600 sq. m.; pop. in 1870, 1,967. The Dubuque and Sioux City railroad passes through it. The chief productions in 1870 were 10,797 bushels of wheat, 21,896 of Indian corn, 6,584 of oats, 6,178 of potatoes, and 4,277 tons of hay. There were 530 horses, 559 milch cows, 998 other cattle, and 353 swine. Capital, Cherokee. **VI.** The S. E.

county of Kansas, bounded E. by Missouri and S. by the Indian territory; area, 604 sq. m.; pop. in 1870, 11,038. The Neosho river skirts the S. W. boundary, and it is watered by Spring river, Lightning creek, and other affluents of the Neosho. The Missouri River, Fort Scott, and Gulf railroad passes through it. The chief productions in 1870 were 54,792 bushels of wheat, 291,916 of Indian corn, 68,059 of oats, 25,603 of potatoes, and 18,883 tons of hay. There were 3,561 horses, 3,002 milch cows, 8,078 other cattle, 2,064 sheep, and 5,791 swine. Capital, Columbus.

CHEROKEES, a tribe of North American Indians, called by themselves Tsaraghee, who when first known by the whites, and down to 1830, occupied the upper valley of the Tennessee river, the mountains and valleys of the Alleghany range, and the head waters of the Savannah and Flint. They form a family by themselves, connected perhaps remotely with the Iroquois. According to their own traditions, they came from the west earlier than the Muskogeans, and dispossessed a moon-eyed people unable to see by day. They were reached by De Soto in 1540, but from their interior position came very slightly into contact with the Spanish, English, or French for many years after the settlements began. They consist of seven families or clans, and, as among the Iroquois, no man can marry in his own clan. From their position they were also divided into two sections separated by the Great Unaka or Smoky mountains, viz.: Otari, the mountain, and Erati, below. They lived in small villages scattered along the streams. The western portion were often at war with tribes at the north, as the middle and lower towns were with the Muskogeans. The Carolinians who shipped Indian slaves to the West Indies encouraged the tribes near them to attack those more remote, and in 1693 twenty Cherokees complained to Gov. Smith, and asked protection against the Esaus, Congarees, and Savannahs, who had destroyed many of their towns and carried off numbers of their people. Gov. Archdale stopped the practice entirely. In 1716 a party of the western Cherokees killed several French officers near the mouth of the Ohio, after which Louisiana endeavored earnestly to win their friendship; but they adhered to the English, serving against the Tuscaroras under Capt. Barnewall in 1712. A chief named Wousatasate received formal investiture from Gov. Nicholson in 1721. They formally submitted to the English king in 1730, when Sir Alexander Cuming was sent to them, and subsequently took six chiefs to England. A few years after a French agent among them named Preber compiled a dictionary and endeavored to win them to France; but he was seized and carried to Georgia. Two years afterward the Cherokees lost nearly half their population by smallpox. This and wars so diminished their numbers that many of their 64 towns were abandoned. In 1755 they ceded

lands to Gov. Glen, and allowed the erection of English forts on their lands. In 1757 their warriors volunteered to protect the frontiers, and they joined the expedition against the French on the Ohio. On their home march, unprovided by the authorities with rations, and with no harvest in their own fields, they took provisions from the settlers. This led to skirmishes, in which a number of Cherokees were killed. They retaliated, and Gov. Lyttleton marched into their country and imposed terms of peace. But hostilities having been renewed, Montgomery and Grant plundered and destroyed many towns, and the Cherokees took Fort Loudon with its garrison. A second expedition under Grant in 1761 completed their overthrow, and peace was made at Long Island in the Holston. The Cherokees had made con-

A Cherokee.

siderable progress previous to this war, which left them without houses, cattle, horses, or implements. During the wars slaves had fallen into their hands, who introduced better cultivation, and thus led to their progress in civilization. Their great chief Oganasdoda soon after visited England. In 1773 Georgia obtained from them the cession of a large tract, the proceeds to be applied to the payment of debts due to traders. At the commencement of the revolution, being under the influence of royal agents, they joined the English, and with the Tories ravaged the frontiers till their country was invaded and laid waste by two columns under Col. Williamson and Gen. Rutherford, when they made peace, surrendering a large tract of land. In 1780 they again took the field and served at Augusta, but were reduced by Gen. Pickens, when Georgia forced them to give up the lands south of the Savannah and east of the Chattahoochee.

By the treaty of Hopewell, Nov. 28, 1785, they acknowledged the sovereignty of the United States, and were solemnly confirmed in the possession of their hunting grounds, embracing much of the present state of Tennessee, with portions of North Carolina, Georgia, Alabama, and Mississippi. Settlements however kept constantly encroaching on these lands, and the Cherokees, advancing in civilization, cultivated more and hunted less. They gave up portions of their territory by the treaties of Holston in 1791 and Tellico in 1798. Owing to this and the general scarcity of game, a portion of the hunters as early as 1790 emigrated beyond the Mississippi, and settled on the St. Francis in the Spanish colony of Louisiana. Some years after a division was made of the property of the tribe between these two parties, and in 1817 the western Cherokees on the Arkansas numbered 3,000, under Takatoka as their chief. The eastern Cherokees, aided by the United States government with agricultural implements, mills, and cotton-cleaning machinery, increased in prosperity; and in 1805, by the treaty of Tellico, for \$14,000 in cash and a perpetual annuity of \$3,000, they ceded a large tract in Tennessee. Although now sedentary and to a considerable extent of mixed blood, the Cherokees were not favorably regarded by Georgia, which demanded their removal in spite of the important services rendered by them in 1812 while serving in Jackson's army, and although by the labors of the Moravian missionaries begun in 1801, followed by the American board of commissioners for foreign missions, the tribe was becoming Christianized. Two parties now arose, the lower towns still clinging to the hunter life, and the upper towns wishing to assimilate to the whites. In the autumn of 1808 delegates of both parties called on the president, the former to express their wish to remove to government lands beyond the Mississippi river. By the treaty of the Cherokee agency, July 8, 1817, lands were ceded to the United States in exchange for lands on the Arkansas and White, government aiding them in transportation. Under this arrangement 3,000 emigrated in 1818. By a treaty the next year making a further cession of lands, the annuities were divided between the eastern and western Cherokees. These continued cessions of land had reduced the Cherokee territory to a mountainous tract of about 8,000 square miles, chiefly within the limits of Georgia. The people of that state still desired their total removal, and actually, by a series of laws officially disregarding their existence as a distinct community, extended jurisdiction over the Cherokee territory, annihilated the tribal government, and by refusing them citizenship, or even the right of being witnesses, placed them in a difficult position. The Cherokees in vain appealed to the United States government; the supreme court of the United States decided that they could not maintain an action in the United States courts,

and the general government admitted its inability to carry out the long series of treaties. Two parties now existed in the Cherokee nation, one led by John Ross opposed to removal, the other under the Ridges and Boudinot in favor of it. At last in 1835 a treaty for general removal was made with a small fraction of the nation, and in 1838 Gen. Scott marched into their country with 2,000 men to enforce it. Their numbers were estimated in all at this time at 27,000, 1,000 remaining undisturbed in North Carolina. The work of removal was committed to the Ross party, who for years were the ruling body and principal medium of treaty with government. Their new site in the Indian territory was further west than the lands given to the western Cherokees, and comprised 9,776,000 acres. Here all their educational and mission works were restored, and provisions supplied for one year. The eastern Cherokees had adopted a constitution and laws which were here put in force, but the western branch opposed them and wished to maintain their old style of government; while in the former body the Ridges still kept up a distinct party. The feuds between the three parties led to acts of violence. In June, 1839, Major Ridge, his son John, and Elias Boudinot were assassinated, and the Ross party became supreme. An act of union between the eastern and western Cherokees was then made, July 12, 1839. In their new home Congregational, Moravian, Baptist, and Methodist mission influence continued hopefully. The printing press, established at Union in 1835 and then removed to Park Hill, continued its work, publishing newspapers and many religious works, partly in English and partly in Cherokee, using for the latter the syllabic characters invented in 1821 by a member of the tribe. (See GUESS, GEORGE.) Salt works, the raising of grain, cotton, cattle, and horses, and the annual annuities, had in 1861 brought them to a high degree of prosperity. The Indian agents being all southern, the Cherokees of all factions at first joined the confederates by treaty of Oct. 7, 1861. Regiments raised by order of the Ross party fought against the United States at Pea ridge; but seeing the struggle doubtful, 9,000 under Col. Downing, the second chief, with a majority of the nation, abandoned the southern cause and came within the Union lines. The remainder, 6,500, chiefly of the Ridge party, adhered to the end to the southern confederacy. In consequence the Ross party confiscated all their lands. The Cherokee territory was now ravaged by both armies, houses and mills were destroyed, and cattle and stock driven off or killed, to the amount of \$2,000,000. The war also resulted in the emancipation of their slaves. The government regarded the Cherokees as having forfeited their lands by rebellion, and imposed the condition that they should give the negroes a portion of their lands or forfeit certain funds held by government.—In 1867 the Cherokees,

by the most accurate census made for many years, numbered 13,566, and the latest estimates give them only 14,682; while in 1853 they numbered 17,367, besides 710 in Haywood co., N. C. Affairs between the Cherokees and the United States were regulated by treaty July 19, 1866, in which protection was given to the Ridge party, some lands were given up to the government, and others set apart for churches and schools. Their country, E. of lon. 96° W. and south of lat. 37° N., now comprises about 5,000,000 acres, two thirds of it being unfit for cultivation. The Cherokee national, orphan, and school funds, held by the United States government, amount to \$1,580,975 35. Their language comprises two dialects, calling each other Oonusta, and a third now lost was called Gidoowa. Although many works have appeared in Cherokee, there is no grammar or dictionary printed. There are some notes on the grammar in the "Cherokee Phoenix" and the *Archæologia Americana*. Under their present constitution they are governed by a national committee and council, elected for two years by the eight districts into which the territory is divided. The executive is called the "principal chief of the Cherokee nation," and is elected for four years. A bill in congress has proposed the erection of the Indian territory into a territorial government under the name of Oklahoma, giving access also to whites; but the Cherokees in 1873 joined the Creeks and Choctaws in an earnest protest against it.

CHERRY. The common cherry tree (*prunus cerasus*, Linn.; *cerasus vulgaris*, Loud.) is of Asiatic origin, and is said by Pliny to have been introduced into Italy by Lucullus from Cerasus in Pontus during the Mithridatic war, about 70 B. C., and about 120 years afterward it was

Common Cherry.

introduced into Britain. It is extensively cultivated in the temperate regions of Europe and America. The Romans recognized eight varieties of it, and more than 300 varieties are

now reckoned in catalogues. The branches are spreading, horizontal, or slightly inclining upward in the larger trees, and drooping in the smaller ones; the flowers are in subsessile umbels, somewhat stalked; the leaves are ovate-lanceolate, smooth, folded together, and of lightest color in the largest varieties; and the fruit is round or heart-shaped, commonly red, but passes into all shades between that color and dark purple. The wood is of a reddish hue, hard and tough, and much used by the cabinetmaker; the gum which exudes from the bark is edible; and the fruit is eaten either fresh or dried, and is made into preserves. The cherry tree is best propagated by grafting on seedlings of the wild cherry.—The wild cherry tree (*cerasus Virginiana*, Loud., and *prunus serotina*, Ehrhart) is one of the largest American forest trees, sometimes attaining a height of 100 ft., with a trunk 3 or 4 ft. in diameter. It is found from Mexico to Hudson bay, and abounds in the

Wild Cherry (*Cerasus Virginiana*).

middle states, and in Kentucky and Ohio. Its wood is compact, fine-grained, and of a dull, light red tint, which deepens with age. It takes a brilliant polish, and is not likely to warp. It is employed by cabinetmakers for almost every species of furniture, and when selected near the ramification of the trunk it rivals mahogany in beauty. Where it abounds, it is used in ship building and for the felloes of wheels. The fruit is purplish black, slightly bitter, and is used for flavoring brandy. This tree is cultivated in Europe for ornament.—The choke cherry (*prunus Virginiana*, Linn.) has often been confounded by botanists with the preceding. It is a tall shrub, seldom a tree, with greenish bark, oblong, sharply serrate teeth, and red fruit, turning to dark crimson, and very astringent till perfectly ripe. It is common on river banks W. of the Alleghenies, and along the Atlantic parts of America, especially northward. Its bark is known to physicians as a tonic. Its fruit affords nour-

ishment to birds, which are said to be sometimes affected by it with a sort of intoxication.—The *prunus avium* (Linn.), or *cerasus sylvestris* (Loud.), is the wild cherry tree of England and continental Europe, and in favorable situations acquires a height of 60 or 70 ft. in about 50 years. Its fruit is known in England by the name of *gean*, and is highly prized in France for the food it supplies to the poor. It is also used to make jelly and cherry brandy. Its wood is manufactured into furniture and musical instruments. Wine casks made of it are said to improve the flavor of wine kept in them.

CHERRY LAUREL (*prunus lauro-cerasus*, Linn.), called in England the common or broad-leaved laurel, is a native of the Levant, and was brought from Constantinople to Holland in 1576. It has racemose flowers, pale evergreen oblong-lanceolate leaves, and is so hardy that neither frost nor drought seems to affect

Cherry Laurel (*Prunus lauro-cerasus*)

it. It is now one of the most popular evergreens in English pleasure grounds, and is almost as common in shrubberies as the rose. Its leaves are poisonous from the abundant hydrocyanic acid which they contain, and should be used with caution. By distillation the laurel water of commerce, the German *Kirschwasser*, and other poisonous cordials, are obtained from them. The fresh leaves are often employed to give a flavor to culinary preparations.

CHERSON. See **KHERSON.**

CHERSONESUS, or **Chersonese** (Gr. *Χερσόνησος*), the ancient designation for a peninsula. The word is not used generally of all peninsulas, and the ancients do not appear to have regarded all such pieces of land partially surrounded by water as we should now designate as peninsulas, in that light. Spain, for instance, and Italy, they never seem to have looked at in their general conformation. What they generally regarded as a chersonese appears to have been a long narrow strip of

land, with its projecting length far exceeding its breadth. Of the larger peninsulas of antiquity four were known as chersoneses, besides many smaller ones scarcely exceeding what we should now call promontories or headlands, the latter word exactly corresponding with what the Greeks called *ἄκρα*. Three of these four have an elongated shape, the other being nearly an irregular parallelogram, connected by a narrow neck with the mainland, and all have narrow straits connected with them, which in two instances are termed bospori. The first is the Thracian Chersonese, now the peninsula of Gallipoli, commonly known to the Greeks as the Chersonesus emphatically; being the long, narrow strip of land running out southwesterly from the mainland of Thrace, between the Hellespont, now Dardanelles, and the gulf of Melas, now of Saros. Not many leagues distant, at the eastern extremity, is the Thracian Bosphorus, now the strait of Constantinople. The second is the Tauric Chersonese, the modern Crimea, which alone has not the elongated shape, but is somewhat fashioned into the semblance of a trapezium. It has, however, a narrow channel, the strait of Yenikale, which is also a bosphorus, called the Cimberian for distinction, across which, before the earliest historic ages, the Scythian Cimberii are said to have been conducted by a heifer; as in later times the Huns are reported to have been introduced under the same guidance. The third is the Cimbric Chersonese, or Jutland with the main part of Schleswig, which has the above described shape and the narrow strait, probably called the Cimbric Bosphorus, between its right flank and the island of Fünen, known as the Little Belt. The last is the Aurea Chersonesus, or Golden Chersonese, the modern peninsula of Malacca.

CHERTSEY (Anglo-Saxon, *Ceorles Eye*, or island), a town of England, in Surrey, situated on a slip of land between the right bank of the Thames and the brook from Virginia water, 22 m. S. W. of London; pop. in 1871, 9,305. A stone bridge with seven arches here connects the counties of Surrey and Middlesex. The town is irregularly laid out, but the streets are paved, and most of the houses are of brick, and it is surrounded by villas. The parish church of St. Anne, partly rebuilt in 1806, has a square embattled tower and a tablet in memory of Charles James Fox, who resided in the neighborhood. The poet Cowley secluded himself in the latter part of his life in the so-called Porch house, Guildford street, where he died. There are a number of educational, charitable, and other institutions, among which is one endowed in 1725 by Sir William Perkins, providing hundreds of children with education, and a number of them also with clothing. The principal trade of the town is in malt, flour, tiles, and bricks, of which latter articles great quantities are made. Vegetables are raised extensively for the London market, and there are annual cattle and sheep fairs, and weekly

markets. The town grew out of a monastery founded in 666, and rebuilt in 964 by King Edgar and the Benedictine monks. No traces of the abbey exist, and the remains of Henry VI. were removed thence to Windsor by Henry VII. Chertsey was a capital of the South Saxon monarchs during the heptarchy.

CHERUB (in Scripture more frequently in the Hebrew plural form, *cherubim*), a symbolical figure of a composite form, which finds a parallel in the composite mythological figures of Assyria, Egypt, Persia, and Greece, of which traces remain in the winged bulls and lions of Nineveh and the sphinxes of Egypt. The most famous cherubim of Scripture were those of gold placed upon the cover of the ark in the tabernacle, facing each other, and apparently adoring an unseen divinity. In the temple of Solomon a pair of colossal size overshadowed the ark with the canopy of their contiguously extended wings. Cherubim were also blazoned on the doors, walls, and curtains of the building. As to the form of the cherubim in the temple there has been much discussion, with no definite result, except a general conclusion that the images were in shape and arrangement very similar to the Assyrian and Egyptian remains referred to above, some of which show a remarkable agreement with the expressions of Scripture. In the sacred boats or arks of the Egyptians represented on the monuments, there are sometimes two figures with extended wings which remind us of the description of the cherubim "covering the mercy seat with their wings, and their faces one to another." Whether the symbolical images were merely symbolical, or were meant to represent beings of actual existence, is uncertain; although a common opinion is that they are ideal representations of the power and wisdom of the Deity. The word cherub (Heb. *kerub*) has been variously explained as meaning strong, great, near, boylike, carven, and grasping or laying hold on. The last meaning, which seems preferable to the others, is chiefly supported by Fürst, who compares the root of the Hebrew *kerub* with similar words in the same language, and with the Sanskrit *grih* and Persian *giriften*, to seize, Greek *γρῦν*, griffin, and the Teutonic *grip*, *greifen*, and *Greif*. The cherubim were always made in pairs, as if to preclude the supposition of an idol which a single figure might have suggested, and in an attitude of subordination to a higher power and glory, setting the example of worship rather than receiving it themselves. They stood like the supporters of a shield, and were repeated in many places about the sacred building like a heraldic device. Yet, perhaps because the priests only entered the holy place, and the ark was covered when moved, their form seems to have been generally unknown. There is mention of cherubim guarding the gates of Eden after the expulsion of Adam, and they also appear in the prophetic visions of Ezekiel and John. In the prophetic visions there

seems in them an entire absence of human sympathy, and even on the mercy seat they appear not merely as admiring and wondering, but as guardians of the covenant and avengers of its breach. In painting and sculpture, the name cherub is given to the winged heads of children which represent angels.

CHERUBINI, Maria Luigi Carlo Zenobio Salvatore, an Italian composer, born in Florence, Sept. 8, 1760, died in Paris, March 15, 1842. He studied under his father, who was a pianist, and in 1769 under Bartolomeo and Alessandro Felici, also under Pietro Bizzari and Giuseppe Castrucci. In 1773 he produced a mass, which, with other of his compositions, attracted the attention of the grand duke Leopold, who enabled him to become a pupil of Sarti of Bologna, under whom he studied from 1778 to 1782. As early as 1780 he produced his first opera, *Quinto Fabio*, at Alessandria, and in 1784 he had already produced eight operas in the theatres of Italy. In that year he went to London, but in 1786 took up his residence in Paris. In 1785 he composed for the London Italian opera *La finta principessa* and *Giulio Sabino*; in 1788 at Turin his *Ifigenia in Aulide*; and in the winter of the same year he brought out his *Demophon*, and in 1791 his *Lodoiska*, at Paris. The latter opera established his fame, and was followed by *Élisa*, *Médée*, *L'hôtellerie portugaise*, *Les deux journées*, *Anacréon*, and his ballet of *Achille à Scyros*. In 1806 he produced *Faniska* at Vienna; in 1809, *Pimmalone* at Paris; in 1813, *Les Abencerrages*; in 1814, *Bayard à Mézières*, in conjunction with Cutel, Boieldieu, and Nicolo; in 1821, *Blanche de Provence*, in concert with Paer, Boieldieu, Berton, and Kreutzer; and in 1833, *Ali Baba*. He excelled most in sacred music. His celebrated mass in F for three voices, his grand *Requiem*, and his *Messe sacre* are the noblest monuments of his genius. Haydn and Beethoven pronounced him the greatest sacred composer of the age. From 1822 till his death he was director of the conservatory of Paris, with which he had been connected from the date of its foundation in 1795, and which is greatly indebted to him for its prosperity. Among his pupils were Boieldieu, Auber, Carafa, and Halévy. Cherubini was never in favor with Napoleon, but from 1816 to 1830 he was superintendent of the music of the king. Adolphe Adam wrote of him after his death: "Contemporary of Haydn, Mozart, Beethoven, and Rossini, Cherubini seems to have been placed by nature among those great geniuses as a moderator, whose wisdom and firmness were destined to counteract their eccentricities."—The most important of Cherubini's literary works is *Méthode de contre-point et de fugue*, published in 1835, containing a summary of the lessons in strict composition which for several years he had given at the conservatory. He was enthusiastically devoted to his profession, and his independence frequently manifested itself.

CHERUSCI, a German tribe, celebrated for their great victory over the Romans under Varus. They are first mentioned by Cæsar. They dwelt on both sides of the Weser, bordering S. on the Suevi, from whom they were separated by the Bacenis forest, probably the western part of the Thuringian mountains, N. E. on the Elbe and the Longobardi, N. W. on the Angrivarii, and S. W. on the Catti. The elder Drusus first led a Roman army through their country, advancing as far as the Elbe; but their ensuing subjection to the empire was soon ended by the great German conspiracy under Arminius, and the destruction of the legions of Quintilius Varus in the Teutoburg forest, in the year 9 of the Christian era. The dissensions, however, which broke out between Arminius and Segestus, his father-in-law, allowed Germanicus to invade their country in the years 15 and 16. He defeated Arminius, but was soon compelled to return. In 17, the Longobardi having gone over from the league of the Marcomanni to that of the Cherusci, Arminius was victorious over Marbod (Maroboduus), the king of the Marcomanni. After the death of Arminius intestine struggles weakened the power of the Cherusci; an ensuing period of peace made them indolent and unwarlike, according to Tacitus, but they still appear as an important people in several later leagues of the Saxon tribes, in whose general name they became merged. They are last mentioned by Claudian, toward the close of the 4th century.

CHERVIN, Nicolas, a French physician, celebrated for his researches into the nature and treatment of yellow fever, born at St. Laurent d'Oingt, near Lyons, Oct. 6, 1783, died at Bourbonne-les-Bains in 1843. In pursuance of his inquiries into the types of fevers, and particularly of typhus, he spent some time in the military hospitals of Mentz, and formed the opinion that typhus is not contagious, but appears so from its rapid propagation. In 1819, Dr. Lassis having contended that yellow fever is no more contagious than typhus, Chervin determined personally to investigate the subject. With this view he set out for the West Indies, and visited successively Santo Domingo, Guadeloupe, Martinique, New Orleans, and Cayenne. During his five years' search he only met with the disease in sporadic cases, never in its epidemic form; but by thoroughly investigating these, and secretly dissecting several bodies, he became convinced that yellow fever is non-contagious. On his return to France he was made a member of the legion of honor, but passed the rest of his life in great poverty, writing innumerable papers to prove that yellow fever is not contagious, and that quarantine regulations neither prevent nor check it.

CHERY, Philippe, a French painter, born in Paris, Feb. 15, 1759, died Feb. 28, 1838. Espousing the cause of the revolution, he took a part in the capture of the Bastille, and was successively a member of the convention, member of the first committee of public safety, mayor

of Charonne and Belleville, and chief of police in the department of the Seine. Banished by Bonaparte after the 18th Brumaire, he did not return to France till 1802. His historical paintings gained for him a high reputation.

CHESAPEAKE BAY, the greatest inlet in the Atlantic coast of the United States. It enters Virginia between Cape Charles and Cape Henry, and extends into Maryland. Its length, following the curve, is about 200 m.; its breadth varies from 4 to 40 m. There is sufficient depth of water for the largest ships to ascend the main bay almost to the mouth of the Susquehanna. The Chesapeake is remarkable for the vast number of arms or estuaries, of various dimensions and of irregular shapes, which mark the line of its shores. Some of these serve as outlets to the rivers of Virginia and Maryland, while others are fed by no permanent streams, but are mere indentations in the coast. Southwest of Cape Henry the rivers and sounds of the Atlantic coast are shallow, and there are few good harbors; but the Chesapeake forms the first of a series of deep and commodious bays which extend along the coast, at no great distance from one another, from Virginia to the N. E. extremity of the United States.

CHESEBRO, Caroline, an American authoress, born in Canandaigua, N. Y., March 30, 1825, died at Piermont, Feb. 16, 1873. Her first stories and sketches appeared in 1848. Her writings are remarkable for purity of diction and the effective use of simple materials. Among them are: "Dreamland by Daylight" (1851); "Isa, a Pilgrimage" (1852); "Children of Light" (1853); "The Little Cross-Bearers" (1854); "The Fisherman's Daughter" (1855); "The Beautiful Gate" (1855); "Victoria, or the World Overcome" (1856); "Amy Carr, or the Fortune-Teller" (1863); "Peter Carradine, or the Martindale Family" (1863); and "The Foe in the Household" (1871). She was for several years a teacher in the Packer collegiate institute, Brooklyn, and contributed regularly to various periodicals.

CHESHIRE, the S. W. county of New Hampshire, bounded S. by Massachusetts, and separated from Vermont on the W. by the Connecticut river; area, 770 sq. m.; pop. in 1870, 27,265. It is drained by the Ashuelot and some smaller streams. The Connecticut is navigable by boats the whole length of the county. The surface is hilly and beautifully diversified by a number of lakes and ponds, and there are some mountains of considerable elevation, the principal of which are Grand Monadnock and Ashuelot. The soil is good, and the river bottoms especially are very fertile. The Cheshire and Ashuelot railroads traverse the county. The chief productions in 1870 were 5,369 bushels of wheat, 7,165 of rye, 146,040 of Indian corn, 104,601 of oats, 263,791 of potatoes, 56,975 tons of hay, 63,278 lbs. of cheese, 531,601 of butter, 110,529 of wool, 151,189 of tobacco, and 227,701 of maple sugar. There

were 3,645 horses, 7,162 milch cows, 3,211 working oxen, 9,171 other cattle, 30,237 sheep, and 3,493 swine. There were 3 manufactories of cotton goods, 16 of furniture, 4 of sashes, doors, and blinds, 38 of wooden ware, 17 of woollen goods, 58 saw mills, 12 tanneries, 6 currying establishments, 3 manufactories of agricultural implements, 7 of boxes, 10 of carriages and wagons, 1 of glassware, 3 of iron castings, 7 of machinery, 1 of wrapping paper, and 4 of hardware. Capital, Keene.

CHESHIRE, or **Chester**, a N. W. county of England, bounded N. by the Irish sea and the estuary of the Mersey; area, 1,105 sq. m.; pop. in 1871, 561,131. It has a level surface, diversified with small lakes called meres, is well wooded, and watered by the Mersey, Dee, and Weaver. It has a clayey or sandy soil; is one of the chief grazing districts of England, and noted for its excellent cheese. Salt, coal, lead, and copper are obtained in plenty, and there are several important manufacturing towns in which silk and cotton fabrics are made to great extent. It is traversed by numerous railways, among which are the North-western, Manchester, and Birmingham, the Chester and Crewe, the Cheshire and Midland, and the Stockport and Liverpool, and by the Grand Trunk and Bridgewater canals. Cheshire was the seat of the ancient Cornavii, and was made a county palatine by William the Conqueror. It remained almost independent of the crown until the time of Henry VIII., and its palatine courts subsisted to the reign of George IV. The county is divided into North Cheshire, Mid-Cheshire, and South Cheshire, each of which is entitled to two members of parliament. Capital, Chester.

CHESNE, André du. See **DUCHESNE.**

CHESNEY, Francis Rawdon, a British soldier, pioneer of the overland route to India, born at Ballyrea, Ireland, in 1789, died Jan. 30, 1872. He entered the army in 1805, became captain in 1815, projected and conducted the Euphrates expedition in 1835-'6, and was brigadier general of artillery in China in 1843-'7, and in the south of Ireland 1848-'52. He became major general in 1855 and a full general in 1868. He wrote "Expedition for the Survey of the Euphrates and Tigris" (1860), "Observations on the Past and Present State of Firearms" (1852), "Russo-Turkish Campaigns of 1828-'9" (1854), and "Narrative of the Euphrates Expedition" (1868).

CHESSE, and **Brome Grass**, common names of several species of the genus *bromus*, belonging to the natural order *gramineæ*, or grasses, and tribe *festuceæ* (fescue grass, &c.). In the wheat-raising districts of the United States the name chess is given particularly to *B. secalinus*, which is also called cheat, and, from its introducer into this country as a grass of supposed value, Willard's bromus. Among the characteristics of the genus are: spikelets with 5 to many flowers, panicle; glumes not quite equal, shorter than the flowers, mostly keeled,

the lower with 1 to 5, the upper with 3 to 9 nerves; the flowers lanceolate, compressed; the paleæ herbaceous, the lower keeled, 5-9-nerved, awned or bristle-pointed from below the tip; the upper palea finally adherent to the grain; stamens 3, styles attached below the apex of the ovary. The grasses of this genus are coarse, with large spikelets, generally somewhat drooping when ripe. The species most known in Great Britain are the *B. erectus*, straight, 2 to 3 ft. high; *B. asper*, 4 to 5 ft.; *B. sterilis*, 1 to 2 ft.; and *B. diandrus*, rarely met.—Of the *B. secalinus*, or chess proper, specific characters are: a spreading panicle, slightly drooping; spikelets ovate, smooth, of a yellowish green tinge, holding 6 to 10 rather distinct flowers. The stems are erect, smooth, round, 2 to 3 ft. in height, bearing 4 or 5 leaves with striated sheaths; joints 5, slightly hairy; leaves flat, soft, linear, their points and margins rough to the touch. This plant is annual,

Chess (*Bromus asper*).

flowering in June and July; but in some cases in which it is cut sooner, or otherwise fails to produce seed, it survives, and matures the second year. Chess is a source of annoyance particularly in grain fields, most of all in those of wheat, since it is difficult to separate its seed, having nearly the size but without the plumpness of barley, from the cultivated grains. The notion of many farmers that wheat which has been injured by frost in the autumn or otherwise arrested in its growth is liable to turn to chess, and that of others that the chess grains themselves never grow, are of course wholly without foundation. Some years since the cultivation of chess as a valuable grass for cattle, like millet, lucerne, &c., was recommended by many persons in this country, probably in ignorance of its really worthless quality, and high prices were charged for the seed; whence doubtless arose its present wide diffusion. It has been supposed that by many who thus disseminated the plant it was mistaken

for the *B. arvensis*, the only species of brome grass at all suitable for cultivation, but which is itself now wholly displaced by more desirable sorts of grasses. In experiments that have been tried with the chess, cattle have been found to prefer to it almost every sort of fodder, save oat straw and corn stalks. It is the farmer's true interest, indeed, to keep his fields as clear as possible of all the species of brome grass.—Among the other species known in the United States are the upright chess (*B. racemosus*), the soft chess (*B. mollis*), declared by some

Soft Chess (*Bromus mollis*).

authorities to be poisonous, the wild chess (*B. Kalmii*), the fringed brome grass (*B. ciliatus*), the meadow brome grass (*B. pratensis*), and the field brome grass (*B. arvensis*). From this last the *B. secalinus* is distinguished by the spikelets of the former having fewer florets, and its outer palea being rounded at the summit.

CHESS (Fr. *échecs*, It. *scacco*, Ger. *Schach*, from Persian *shah*, king, the principal piece in the game), the oldest and most scientific of sedentary amusements, originated in India about 5,000 years ago. Its history may be divided into three periods: 1. The age of the *chaturanga*, or primeval Indian game, extending from its origin down to about the 6th century A. D. In the *chaturanga* the moves of the men were almost the same as in the present game, but it was played by four persons, and the combatants determined what piece to move by the throw of a die. 2. The age of the *shatranj*, or mediæval game, embracing the period between the 6th and 16th centuries. In the *shatranj* the game was reduced to a contest between two persons, and the element of chance was discarded. Early in this stage of its history the game passed eastward into China and Japan, where in the lapse of time it has been considerably modified, and westward through Persia and Byzantium into Europe, where it became during the middle ages the favorite indoor pastime of the court and the cloister.

3. Modern chess includes the period from the commencement of the 16th century to the present day. It is distinguished by some changes in the fundamental laws of the game, such as an increase in the powers of the queen and bishop, and the introduction of castling.—Chess is now cultivated by all civilized nations, and its theory and practice have been investigated by innumerable writers of ability. The most prominent are, among Asiatics, Ali Shatranji, Suli, Damiri, Sokeiker, Rhazes, Ibn Sherf Mohammed, and Ghulam Kassim; and among Europeans, Jacobus de Cessolis, Conrad von Ammenhusen, Alfonso the Wise, Lucena, and Vicent, before the close of the 15th century; Damiano, Ruy Lopez, and Gianuzio, in the 16th century; Salvio, Carrera, Augustus duke of Brunswick, Greco, and Saul, in the 17th century; Bertin, Stamma, Philidor, Del Rio, Lolli, Ponziani, Cozio Stein, Zuylen van Nieveld, and Allgaier, in the 18th century; and Koch, Sarratt, Cochrane, Lewis, Bilguer, Von der Lasa, Bledow, Alexandre, Walker, Jänisch, Calvi, and Staunton, in the 19th. The poetry of chess has been illustrated by Vida, Middleton, Tuccius, Kochanowski, Sir William Jones, Cerutti, Méry, D'Arblay, Slous, Tomlinson, and others. Sarrasin, Fréret, Hyde, Severino, Leibnitz, Jones, Wahl, Twiss, Madden, Bland, and, most thoroughly of all, Forbes, have explored its history. The most famous players of the last 400 years have been Paoli Boi, Leonardo da Cutri, Salvio, Del Rio, and Dubois, of Italy; Ruy Lopez and Xerone, of Spain; Legal, Philidor, Deschappelles, and La Bourdonnais, of France; Cunningham, Stair, Janssen, Sarratt, McDonnell, and Staunton, of England; Allgaier, Bilguer, Hanstein, Mayet, Von der Lasa, Anderssen, Lange, and Harwitz, of Germany; Petroff and Kieseritzky, of Russia; Szén and Löwenthal, of Hungary; Stein, of Holland; Stamma, of Syria; and Morphy, of the United States. During the present century the popularity of the game has largely increased, owing to the establishment of chess periodicals, to the interest attaching to public contests between great players or between different clubs, and to the influence of assemblies or conventions of amateurs, such as the tournament held at London in 1851, and the congress which met at New York in 1857.—Chess is played by two persons on a board of 64 alternately white and black squares, each player having 16 men, 8 pieces and 8 pawns. The player, having placed the board so that he has a white corner square at his right hand, may place the white men as follows: the queen's rook in the left hand corner nearest him; the queen's knight in the square next to it; then successively the queen's bishop, the queen, the king, the king's bishop, the king's knight, and the king's rook, until he reaches the right side of the board. The white pawns are then placed on the 8 squares immediately in front of the pieces; and the black pieces and pawns are to be arranged in the same manner on the opposite side of the board.

Chess Board.

The following rules describe the moves of the men and the laws of the game :

1. The rook moves in straight lines parallel with the sides of the board. 2. The knight moves from the square upon which it stands, to any one of a different color, at a distance of three squares, counting the one from which it starts. 3. The bishop moves diagonally, forward and backward, in a line composed of squares of a like color. 4. The queen moves at pleasure, either like the rook or bishop. 5. The king moves one square in any direction. All the pieces capture in the same direction in which they move. 6. The pawn moves directly forward; its first move may be either one or two squares, but each succeeding move is limited to one square. The pawn captures diagonally, to the right or left, one square forward. All the men capture by removing the captured man and placing the capturing one on the square thus rendered vacant. No man can pass over any occupied squares, except the knight, the move of which piece has no such restriction.—Castling is a double move of the king and rook at the same time. Castling on the king's side is performed by moving the king to king's knight's square (g 1 or g 8), and the king's rook to king's bishop's square (f 1 or f 8); on the queen's side, by moving the king to queen's bishop's square (c 1 or c 8), and the queen's rook to queen's square (d 1 or d 8). Castling is permitted to either player once during the game, under the following conditions: 1. Neither of the castling pieces can have been moved; 2. the squares between the king and the rook must be vacant; 3. the king must not be in check; 4. the squares upon which the king and rook, after castling, are to stand, must not be commanded by any of the adverse men.—When a pawn, in moving two steps, passes over a square commanded by an adverse pawn, it may be captured by the adverse pawn in passing, in the same manner as if it had moved but one square. When a player has no other move at command, capturing the pawn in passing is compulsory.—Every pawn, upon reaching the eighth or last rank, ceases to be a pawn, and must be immediately exchanged for a queen, a rook, a bishop, or a knight, even though none of these pieces may have been previously lost.—A man touched must be moved, and an adversary's man touched must be captured, unless the player touching the man previously says, *J'adoube* (or, I replace).—Whenever a player attacks the adverse king, he shall audibly utter the word "Check!" either just before or at the time the attacking move is made.—The king is checkmated when he is attacked by any of the adverse men, and cannot in any way escape from the attack. Checkmate finishes the game, and should always be audibly announced. But whether it be announced or not, the game is equally won by the mating player. No game can be won except it end with a checkmate.—The game is drawn, or won by neither party, in the following cases: 1, when one player gives perpetual check, or when both players insist upon a continual repetition of the same moves; 2, when either king is stalemated, that is, when the king of one of the players is not in check and cannot move to any square not commanded by an adverse man, and when that player possesses no other man which can be legally moved; 3, when neither party possesses a force sufficient to effect mate.

In recording games it is usual to style the square upon which the king stands the king's

square; the one immediately in front, the king's second square, &c. The different methods of commencing a game are styled openings, and have frequently received names from their inventors or chief illustrators. The most common openings are the following :

Chess problems are positions supposed to have occurred at the ends of games, in which one party agrees to checkmate or draw the game in a certain number of moves. The following are specimens :

I.—By Cook.

BLACK.—K. at K. Kt. 7th, Ps. at K. Kt. 6th and K. B. 5th. White to play and mate in three moves.

—In the numerous legends and curious anecdotes which adorn its annals, in its venerable nomenclature, which has been transmitted through all the changes of language, from the earliest tongues of the Indo-European stock to the latest, in its singular combination of idle amusement and mental toil, and in the fascination which it has ever exercised over its votaries, chess forms a remarkable chapter in the history of the world. Monarchs like Haroun al-Rashid, Charlemagne, Tamerlane, Charles XII., Frederick the Great, and Napoleon I., and philosophers like Leibnitz, Voltaire, Rousseau, and Franklin, have found delight in its study and pleasure in its practice. Alone among games its use has been sanctioned by the priesthood of all beliefs, Catholic, Protestant, Buddhist, and Moslem. Erudite writers have illustrated its history, and acute intellects have elaborated its theory, until it has at length become the subject of a large and pleasant literature.

CHEST. The human body being commonly divided into head, trunk, and limbs, these again are subdivided into head and face, chest and abdomen, upper and lower limbs. The chest, then, is the upper portion of the trunk, to which are attached externally the breasts in front, and the arms and shoulders laterally and posteriorly, and the cavity of which contains internally the heart and lungs. The walls of the chest are composed mainly of the ribs and the muscles pertaining to the ribs; the dorsal portion of the spinal column completes the walls of the chest behind, and the sternum completes them in front. The neck connects the chest with the head, and the midriff or diaphragm divides internally the cavity of the chest from that of the abdomen. The upper portion of the chest, between the spine, first ribs, and the sternum, forms an aperture through which the trachea passes into the chest, and the great arteries and veins of the head, neck, and arms pass out of the chest from the heart and main vessels. The spaces between these vessels and the bones are occupied by the œsophagus, by certain nerves and muscles, and by what is termed cellular or connective tissue. The whole chest thus forms a cavity closed on all sides, but allowing the passage of certain tubes or vessels through the upper and the lower portion of its walls, such as the trachea, œsophagus, blood vessels, nerves, &c. This cavity contains within it three subordinate cavities, the middle one containing the heart sheathed in the pericardium, and the two cavities at the sides containing the lungs, sheathed by the pleural serous membranes, and called the pleural cavities. Each lung is suspended, as it were, in its appropriate cavity by its bronchus from the trachea, and by the trunks of its pulmonary artery and veins, which,

bound together by connective tissue, form what is called the root of the lung. For the sake of easy motion, the wall of the cavity is lined, and the surface of the lung is covered by a smooth membrane called the pleura, the contiguous surfaces of which are moistened with serous fluid to prevent friction from alternate respiratory motions of the chest and lungs. The pleural cavities being completely closed on all sides, no air can enter them, but the lung in each cavity communicates with the external air by means of its bronchial tubes leading to the trachea and larynx, through which the air passes, not into the cavity of the chest, but into the interior of the lung. In their medium state, the lungs of a person of ordinary size and in good health contain about 200 cubic inches of air. In easy breathing, about 20 cubic inches is drawn into them at each inspiration; but this may vary considerably, according to the efforts made in muscular exertion, or during singing, or before coughing. The limit which the rigidity of the walls of the chest sets to the elastic collapse of the lungs is never reached in ordinary respiration, and the lungs accordingly are never entirely emptied of air.

CHESTER. 1. A S. E. county of Pennsylvania, bounded S. and S. E. by Maryland and Delaware, N. E. by the Schuylkill river, W. by Octorara creek, and drained by French, Elk, and the sources of Brandywine creeks; area, 738 sq. m.; pop. in 1870, 77,805. It formed one of the three original counties of the province established by William Penn in 1682. The surface is much diversified. A rich limestone valley about 2 m. wide, extending from the Schuylkill to the Susquehanna, divides the county into two nearly equal parts, of which the southern is rolling or gently undulating, with rich deposits of chromate of iron, valuable porcelain clay, and gneiss; while the northern is rugged, and contains gneiss, sandstone, red shale, copper, and abundance of lead and iron. The N. W. boundary is formed by a low ridge called Welsh mountain. Besides the minerals above mentioned, there are silver, zinc, titanium, zircon, agate, chalcidony, amethyst, sapphire, and beryl. The valley yields excellent limestone and marble. Agriculture is carried to great perfection. The county is traversed by the Pennsylvania Central and Waynesborough branch, the West Chester and Philadelphia, and the West Chester railroads, and by the Philadelphia and Baltimore Central railroad. The Philadelphia and Reading railroad passes along its N. E. border. Valley Forge and Paoli, of revolutionary fame, are in this county, which also contains the birthplace of Gen. Anthony Wayne. The chief productions in 1870 were 753,803 bushels of wheat, 1,540,125 of Indian corn, 1,034,430 of oats, 404,363 of potatoes, 114,898 tons of hay, 2,848,243 lbs. of butter, and 31,776 of wool. There were 14,086 horses, 32,670 milch cows, 21,916 other cattle, 13,069 sheep, and 28,165 swine. There were 32 manufactories of car-

riages and wagons, 14 of brick, 5 of cotton goods, 6 of hubs and wagon material, 13 of iron, 1 of nails and spikes, 8 of iron castings, 19 of lime, 5 of machinery, 26 of paper, 10 of woollen goods, 7 wool-carding and cloth-dressing establishments, 99 flour mills, 6 tanneries, and 23 saw mills. Capital, West Chester. **II.** A N. county of South Carolina, bounded E. by the Catawba, and W. by Broad river; area, 570 sq. m.; pop. in 1870, 18,805, of whom 12,513 were colored. The surface is uneven, but the soil is fertile. The Charlotte, Columbia, and Augusta, and the King's Mountain railroads traverse it. The chief productions in 1870 were 32,210 bushels of wheat, 169,379 of Indian corn, 22,496 of oats, 13,464 of sweet potatoes, and 7,042 bales of cotton. There were 1,292 horses, 1,781 mules and asses, 2,550 milch cows, 2,085 other cattle, 1,933 sheep, and 6,856 swine. Capital, Chesterville.

CHESTER, a city of Delaware co., Penn., situated on the Delaware river and on the Philadelphia and Wilmington railroad, 10 m. S. W. of Philadelphia; pop. in 1870, 9,485. It is the oldest town in the state, having been settled by the Swedes in 1643, and was originally called Upland. The provisional assembly was held here under the government of William Penn in 1682. It was the county seat of Chester co. until Delaware co. was organized in 1789. In 1871 there were 23 schools, of which 2 were high schools, 26 teachers, and 465 male and 464 female pupils in attendance. Three weekly newspapers are published.

CHESTER, an episcopal city, port, and parliamentary and municipal borough of England, capital of Cheshire, and a county in itself, situated on the Dee, 17 m. S. S. E. of Liverpool, and 164 m. N. W. of London; pop. in 1871, 35,701. It was a Roman station called *Deva* or *Deva Castra*; was known to the Britons as *Caer Lleonvawr*, and by the Saxons was styled *Legancester* or *Legecester*. It stands on a high rock, nearly encompassed by the Dee, and is surrounded by walls and towers, the substructure of which is probably Roman, while the upper portion dates from the time of Edward I. These walls are in excellent preservation, and are thought to be the most perfect remains of ancient fortification in England. They are from 5 to 8 ft. thick, and on their summit is a walk with parapets, from which may be obtained extensive and beautiful views. The space which they enclose is a parallelogram, planned like the Roman camps, with a gateway in the middle of each side, and two main streets intersecting at right angles in the centre of the town. These are remarkable for being sunk far below the lowest inhabited portions of the houses, and below the footways, which are within piazzas called rows. The latter consist of broad paved walks underneath the second floors of the houses, with balustrades in front, and shops on the inner side. There are stairways at intervals leading down to the road. The side streets run at right angles. A

supply of water is obtained from the Dee. The town contains many curious wooden dwelling houses of venerable age, perhaps the most interesting of which is Stanley house, a very ancient

Watergate Row, Chester.

three-gabled building, ornamented with elaborate carving. It is now occupied by the Chester archaeological society. A round tower connected with the city walls bears an inscription stating that from its summit King Charles beheld the defeat of his army on Rowton Moor in 1645. In Bridge street are a Roman *hypocaustum* and sweating chamber in remarkably

Stanley House, Chester.

good preservation. The castle, originally built by Hugh Lupus, earl of Chester, and governor of the province under William the Conqueror, has been almost wholly reconstructed in mod-

ern times, and is now used as the shire hall, county jail, armory, and barracks. Near the castle a handsome stone bridge crosses the Dee with a single arch of 200 ft. span. The Chester and Holyhead railway, which has here one of the largest stations in the kingdom, also crosses the Dee on an iron girder bridge. The cathedral, originally the abbey of St. Werburgh, built for the Benedictines in 1095 by Hugh Lupus, assisted by St. Anselm, is a remarkable Gothic structure, full of interesting memorials. There are 11 other churches, 9 of which are parochial, the most important being St. John's collegiate church, once considered the cathedral. It is a very ancient building, and was mentioned in the Domesday survey. It was formerly partly in ruins, but has been thoroughly restored. The restoration was commenced in 1868, and the completion was celebrated in January, 1872. The arches and piers of the nave are probably Norman; the choir has been rebuilt, and the transepts were entirely destroyed at the reformation. The Roman Catholics and dissenters have a number of places of worship. There is a grammar school, founded in the time of Henry VIII., and called the king's school, under the direction of the dean and chapter of the cathedral. Among the other institutions are a normal college, many charity schools, an infirmary, house of industry, almshouses, linen hall, exchange, union hall, and commercial hall, mechanics' institute and museum, a government school of art, library, savings bank, theatre, and public baths. There are three public parks and a cemetery in the environs, and not far distant are Saughton Grange, a curious manor house once belonging to the abbey of St. Werburgh, and Eaton hall, the seat of the marquis of Westminster. Famous races have been held here from a remote date. Fairs for the sale of cheese take place monthly, other fairs three times a year, and markets twice a week. Ship building, formerly on the decline, has been revived by judicious improvements in the river Dee. The manufactures include rope and sail making, paint, shot, lead pipe, whips, thread, gloves, and tobacco. The shipping trade is almost exclusively coastwise. The exports are cheese, lead, calamine, copper plates, cast iron, and coal; the imports, butter, provisions, hides, tallow, timber, iron, hemp, hops, wine, and oil. Chester is connected by the Ellesmere canal with Liverpool, and by railway with Liverpool, Holyhead, Shrewsbury, and Crewe. Recently various alterations and improvements have been made in the town; many new buildings have been erected, including a town hall at a cost of \$100,000, a market hall, two extensive hotels, and several chapels. Chester gives the title of earl to the prince of Wales, and sends two members to the house of commons.—In 1858 was published in London, "The Mediæval Architecture of Chester," by J. H. Parker.

CHESTERFIELD. I. A S. E. county of Virginia, bounded S. by the Appomattox, and N.

E. by James river; area, 300 sq. m.; pop. in 1870, 18,470, of whom 8,733 were colored. The surface is uneven and most of the soil poor, though the river bottoms are fertile. Coal is found in large quantities. It is traversed by the Richmond and Petersburg railroad and Clover Hill branch; the Richmond, Danville, and Piedmont railroad passes through the N. part. The chief productions in 1870 were 46,408 bushels of wheat, 150,485 of Indian corn, 74,475 of oats, and 194,510 of tobacco. There were 925 horses, 1,580 milch cows, 1,082 other cattle, 2,122 sheep, and 6,693 swine. There were 5 manufactories of cotton goods, 2 of chewing and smoking tobacco, 5 flour mills, 1 manufactory of iron castings, 1 of prepared husks, 1 of twine, 1 of wooden ware, 1 tannery, and 2 saw mills. Capital, Chesterfield Court House. II. A N. E. county of South Carolina, bordering on North Carolina, bounded S. W. by Lynch's creek, N. E. by Great Pedee river, and drained by a number of small streams; area, 868 sq. m.; pop. in 1870, 10,584, of whom 4,309 were colored. It is much diversified by hills and valleys, and fertile near the streams. The Cheraw and Darlington railroad passes through it. The chief productions in 1870 were 21,921 bushels of wheat, 118,129 of Indian corn, 22,550 of oats, 19,949 of peas and beans, 52,732 of sweet potatoes, 2,457 bales of cotton, and 10 hhds. of sugar. There were 804 horses, 2,606 milch cows, 5,678 other cattle, 3,396 sheep, and 13,316 swine. Capital, Chesterfield Court House.

CHESTERFIELD, a town, parish, and municipal borough of Derbyshire, England, situated on the Midland railway, at the junction of the rivers Hipper and Rother, 20 m. N. of Derby; pop. in 1871, 11,426. It is tolerably well paved, lighted with gas, and supplied with water. The houses are of brick or stone, irregularly but substantially built, and roofed with tiles or slates. The parish church, a Gothic building of the 13th century, with a twisted spire 230 ft. high covered with lead, two other churches, a new and an old town hall, various chapels, a handsome school house for a free grammar school founded under Elizabeth, alms houses, a savings bank, and a mechanics' institute, are the chief buildings of note. The manufactures are lace, silk, gingham, and earthenware. Considerable trade is carried on in malt, and there are coal mines, quarries, and smelting furnaces in the vicinity. The Chesterfield canal connects the town with the river Trent.

CHESTERFIELD, Philip Dormer Stanhope, fourth earl of, born in London, Sept. 22, 1694, died March 24, 1773. He was educated at Cambridge, and early entered public life, having been elected to the house of commons before he was of age. By the death of his father he became an earl in 1726, and in the following year was sworn a privy councillor, and in 1728 was sent ambassador to Holland, where he remained four years. He was sent as ambassador a second time to Holland in 1745, but re-

turned in a few weeks, to assume the viceroyalty of Ireland, where he distinguished himself by a firm and enlightened administration. George II. recalled him from Ireland in April, 1746, and appointed him principal secretary of state. He retired from official life in 1748, but still continued to give attention to public affairs until incurable deafness caused him to pass into private life. In 1751 he introduced into parliament, together with the earl of Macclesfield, the bill for the reformation of the calendar, in favor of which he made an elaborate and convincing speech. He was remarkable for sparkling wit, elegant manners, solid talents, and attention to business. Besides his fame as a diplomatist and a statesman, he has a reputation as the author of a remarkable series of letters on a large range of social, philosophical, literary, and political topics, written to his son, and published after his death by that son's widow. Their moral tone is low, their chief object being to inculcate a refined selfishness, but they contain many valuable suggestions on manners. A collection of his letters to other individuals, and of his speeches and miscellaneous writings, has been published, full of wit, knowledge of the world, and tersely expressed views of the public men of Europe. The best editions of Lord Chesterfield's letters and miscellanies are by Lord Mahon (London, 1845 and 1853).

CHESTERFIELD INLET, an arm branching from the N. W. angle of Hudson bay, British America, 250 m. long, and 25 m. across at its widest part. It receives the waters of several rivers, and contains numerous small islands.

CHESTER-LE-STREET (Saxon, *Conceastre*), a parish and village of England, county of Durham, on a Roman military road, and near an ancient Roman station, 6 m. N. of the city of Durham; pop. of the parish in 1871, 33,287. Its parish church, dedicated to St. Cuthbert, whose remains are said to have rested here for 113 years before their removal to Durham, and to St. Mary, is an imposing Gothic building, with a handsome tower, and a spire 156 ft. high. It contains the stone effigies of the lords of Lumley, 14 in number, from Lyulph, the Saxon founder of the family, to the time of Elizabeth. The see of a bishop was removed hither from Lindisfarne about 880, and remained till 995, when the prelate and clergy were expelled by the Danes. The bishopric was then fixed at Durham. The village is lighted with gas, and contains manufactories of rope, nails, and tiles. There are coal mines, brass and iron works, corn mills, paper mills, fire-brick yards, a steam engine manufactory, and a productive salt spring in the vicinity. Near here also are Lumley castle, a seat of the earl of Scarborough, Lambton hall, belonging to the earl of Durham, and Ravensworth castle. The first mentioned is an interesting building, supposed to have been founded in the 14th century.

CHESTNUT (*castanea vesca*, Linn.; *castanea vulgaris*, Lamb.), a large and handsome tree,

valuable both for its timber and fruit, and growing wild in Europe and the United States. Its foliage is ample and graceful, with long patulous boughs; oblong-lanceolate leaves, serrate with pointed teeth, and smooth and green on both sides; clusters of sterile flowers in long, cream-colored, cylindrical catkins; and fertile flowers two or three together in an ovoid prickly involucre at the base of the catkins. There is no corolla; the calyx is 5 or 6 lobed, placed on the summit of the 3-7 celled ovary, and enclosing 5-20 stamens, and 3-7 bristle-shaped stigmas; the nut is ovoid, coriaceous, and farinaceous. The chestnut is among the most beautiful of forest trees, and is conspicuous in the landscapes of Salvator Rosa and other masters. It is common in the forests of southern Europe from the Caucasus to the Atlantic, preferring deep sandy soils and the sides of mountains, and avoiding marshy regions. It is said to have been found by the Romans

Chestnut (*Castanea vesca*).

first at Castanea, a town of Thessaly, near the mouth of the Peneus, whence the fruit was named by them *Castanea nux*. Some of the oldest and largest trees in the world are of this species. One of the most famous is that on Mount Etna, which has often been described by travellers, and can be seen from Aci Reale. It is 160 ft. in circumference, and has a hollow trunk, the interior of which serves as a retreat for shepherds and their flocks. It is called the hundred-horse chestnut, from a tradition that Joanna of Aragon once visited it, accompanied by all the nobility of Catania, and that the whole party found protection beneath it from a sudden storm. One of the oldest chestnut trees in England is at Tortworth, in Gloucestershire, which was a boundary mark in the reign of King John; and in France there is a remarkable one at Sancerre, which is believed to be about 1,000 years old, and is still very productive. The chestnut furnishes an excellent and durable timber, which has been thought to be the material of the roof of

Chestnut Tree of Mount Etna.

Westminster abbey, and of the church at Great Yarmouth, erected in the reign of William Rufus; but the wood of both those buildings is more probably a species of oak. The fruit is eaten either raw, boiled, or roasted, or is ground into meal, and puddings, cakes, and bread made from it. It abounds especially in France, on the banks of the Rhine, and on the slopes of the Jura, the Pyrenees, and the Alps; and of the numerous French varieties the most esteemed is the *marron*. The American chestnut has sometimes been separated from the European as a distinct species, but upon insufficient grounds.

It is also used for the commoner kind of cigar boxes. The European chestnut was introduced into Virginia by Jefferson in the latter part of the last century.—There is a smaller American species, the chinquapin nut (*castanea pumila*, Michaux), found from Ohio to southern Pennsylvania, growing from 6 to 20 ft. high, having its leaves whitened-downy underneath, and a solitary nut not half so large as the common chestnut, and very sweet and agreeable to eat.—An infusion of the bark of the chestnut has been occasionally employed in medicine. Its action is that of a moderate astringent and tonic, but it has never been much used.

CHEETAH. See LEOPARD.

CHEVALIER, Michel, a French political economist, born in Limoges, Jan. 13, 1806. He studied at the polytechnic and the mining schools, and was appointed engineer in the department of Le Nord. After the revolution of July, 1830, he joined the disciples of Saint Simon, and was intrusted with the editorship of their official organ, the *Globe*. He participated in all the proceedings of the apostles of the new faith, and shared the penalties they incurred, being sentenced to a year's imprisonment; but he was leniently dealt with by the government, and released at the expiration of six months. He was sent to the United States by M. Thiers, then minister of commerce, to investigate the American system of railroads. He arrived in New York toward the end of 1832, travelled during two years over the United States, Mexico, and Cuba, and published the results of his observations in a series of letters in the *Journal des Débats*, which were in 1836 collected under the title of *Lettres sur l'Amérique du Nord*. Another work, *Des intérêts matériels en France*, which

Chinquapin (*Castanea pumila*).

It has, however, smaller and sweeter nuts. It is found in rocky or hilly woods from Maine to Michigan and Kentucky, and its wood is chiefly in esteem for posts and rails to construct fences.

appeared in 1838, a brilliant sketch of the internal improvements planned by M. Molé, was received with equal favor. In 1840 Chevalier entered the council of state and the superior board of agriculture and trade, succeeded M. Rossi in the professorship of political economy at the collège de France, and a few months later was promoted to the rank of chief engineer of mines. In his *Histoire et description des voies de communication aux États Unis* (2 vols., 1840-'42), he gives a full account of American railroads, with a view of their influence upon social intercourse. His lectures at the collège de France became very popular, and he continued his contributions to the *Journal des Débats*. In 1845 he was elected to the chamber of deputies by the department of Aveyron; but his free-trade doctrines prevented his reelection. He became the standard-bearer of the free-trade party, advocating his opinions in occasional pamphlets in the *Débats* and in the *Revue des Deux Mondes*. In the latter periodical, after the revolution of 1848, he opposed the doctrines supported by Louis Blanc in the conferences at the Luxembourg; the papers directed against the socialist apostle were entitled *Question des travailleurs*, and had their complement in the *Lettres sur l'organisation du travail*, which appeared in the *Débats*. This contest, in which Chevalier evinced anti-revolutionary sympathies, caused his dismissal from his professorship during the provisional government; but he afterward regained official favor, and was reinstated in his chair at the collège de France, and his seat at the council of state. In 1851 he was elected a member of the academy of moral and political sciences. He was one of the commissioners of the universal exposition of 1855 in Paris, and was president of the French division of the jury at the exhibition in London in 1862. In 1860 he assisted Mr. Cobden in negotiating the commercial treaty between France and England; and the same year he was appointed senator, and took a prominent part in the discussion of important subjects relating to finance and industry. To him was intrusted the publication of the official report on the different classes of articles exhibited at the universal exposition of 1867 in Paris, and he wrote the introduction, in which the entire subject of modern industry is philosophically treated. This was published in 1868 under the title *Exposition universelle de 1867 à Paris, rapports du jury international*. In 1866 he was a member of the commission to investigate the state of agriculture, and in 1869 was made president of the international league of peace. Besides the works already mentioned, he has published *L'isthme de Panama, suivi d'un aperçu sur l'isthme de Suez* (1844); *La liberté aux États Unis* (1849); *Examen du système commercial connu sous le nom de système protecteur* (1851); *Questions politiques et sociales* (1852); *La question de l'or* (1853); *De la baisse probable de l'or, &c.* (1857); *L'expédi-*

tion du Mexique (1862); *Le Mexique ancien et moderne* (1863); *Cours d'économie politique* (3 vols., 1842-'50; new ed., 1866); and *La guerre et la crise européenne* (1866). Many of his works have been translated into English.

CHEVERUS, Jean Louis Anne Madeleine Lefebvre de, a French prelate, the first Roman Catholic bishop of Boston, Mass., born at Mayenne, Jan. 28, 1768, died at Bordeaux, July 19, 1836. After completing his classical and theological studies, he was admitted to the priesthood in 1790, and officiated for some time as a curate at Mayenne; but on his refusal to take the oath ordered by the assembly, he went to England, and became a teacher of French and mathematics in a private Protestant school. In 1795 he proceeded to the United States, and joined the Catholic mission at Boston. The members of that church were then but few in number; his well directed efforts gathered new adherents, while his affability, simple and winning manners, fluency of speech, and inexhaustible benevolence, made him popular even among other religious denominations. From Boston he went to Newcastle, Maine, where he founded a Catholic church, and spent three months in missionary labors among the Indians on the Penobscot river, and in the vicinity of Passamaquoddy bay. He was recalled to Boston, where the yellow fever was then raging with great severity, and gave renewed evidence of courage, devotion, and benevolence, which extended to all persons without distinction of creed. When he opened a subscription for the building of a Catholic church in Boston, he found assistance among Protestants, President John Adams heading the list. In 1808 he was appointed by Pius VII. first bishop of Boston, and was consecrated as such notwithstanding his entreaties and objections. He continued to attend to the humblest duties of the ministry, and to visit every year the Penobscot Indians. After living in Boston for nearly 30 years, he was recalled to France by Louis XVIII., who in 1823 appointed him to the bishopric of Montauban. The vicinity of that town having been devastated by a flood, the bishop opened his residence as an asylum to all the sufferers. His popularity throughout France became at least equal to that he had enjoyed in America. A vacancy having occurred in the archbishopric of Bordeaux, he was appointed to that office, and was at the same time created a peer of France by Charles X. His career at Bordeaux was signalized by the establishment of several charitable institutions. When the cholera broke out in that city his palace was again turned into a hospital, and at the entrance he caused to be inscribed the words, *Maison de secours*. He was also instrumental in calming the exasperation of the people, who attributed the disease to poisoning. On the revolution of July he lost his rank as peer of France, and declined receiving it back at the hands of Louis Philippe. He had no taste for offices or honors of any kind, but could not prevent the king

from soliciting for him the dignity of cardinal, to which he was appointed Feb. 1, 1836; but he died of apoplexy within less than six months. Two translations of his life by M. Hamon of St. Sulpice (under the name of J. Huen-Dubourg) have appeared in the United States.

CHEVES, Langdon, an American statesman, born at Rocky River, S. C., Sept. 17, 1776, died at Columbia, June 25, 1857. He received little early education, but was admitted to the bar in 1800, and rapidly attained eminence. In 1808 he was elected from Charleston to the general assembly, of which body he became a leader. He was a representative in congress from 1811 to 1816, and was a zealous supporter of the party which carried the declaration of war. His speech on the merchants' bonds in 1811 was admired both for its ability and eloquence. He was chairman of the naval committee in 1812, and of the committee on ways and means in 1813, and constantly opposed the restrictive system. When Henry Clay was sent as commissioner to Ghent, Mr. Cheves succeeded him as speaker of the house, being elected by the federalists combined with the anti-restriction democrats over Felix Grundy, the candidate of the strict administration party. He retained this office till 1815, and not one of his decisions was reversed by the house. The bill for the recharter of the United States bank in 1815 was lost by his vote. He voted first to make a tie, and then gave a second and casting vote to defeat it. Declining a reelection to congress after the close of the war, he was chosen one of the superior judges of the courts of law of South Carolina. The national bank having been rechartered in 1816, that institution under injudicious management had become hard pressed and was on the verge of stoppage in 1819, when Cheves was elected president of its board of directors. By a rigorous system of retrenchment, and by making credits only upon sufficient securities, the bank was saved, and specie payment maintained at the principal centres of commerce. Resigning this arduous office after three years, he became chief commissioner under the treaty of Ghent for settling some of its provisions. He returned to South Carolina, where he devoted himself to his plantation, and though retaining his interest in public affairs, declined to accept public office. Although as early as 1830 he had favored a withdrawal of the South from the Union, he was opposed to the scheme of nullification of 1832. Though advocating a southern confederacy, he opposed the unsupported action of a single state as suicidal. In 1850 he became a delegate to the Nashville commercial convention, and in 1852 was a member of the state convention of South Carolina, in which he exerted his influence against the idea of separate state secession. As a literary man he is known not only by his speeches, but by many occasional letters and reviews. He was buried with public honors in the Magnolia cemetery, near Charleston.

CHEVIOT HILLS, a mountain range, extending about 35 m. from N. E. to S. W. between Northumberland, England, and Roxburghshire, Scotland. They afford good pasturage for sheep, and give their name to a fine breed of that animal. They were the scene of many bloody battles between the Scotch and English, the most famous of which is that immortalized in the celebrated ballad of "Chevy Chase." Cheviot peak, 15 m. E. of Jedburgh, is 2,677 ft. high.

CHEVREUL, Michel Eugène, a French chemist, born at Angers, Aug. 31, 1786. Having completed his studies in the central school of Angers, he studied chemistry under Vauquelin in Paris, and afterward took charge of the laboratory of that chemist. In 1810 he became preparator of the chemical course in the museum of natural history, and in 1813 professor in the lycée Charlemagne. In 1824 he was appointed director of the dye works and professor of special chemistry at the Gobelins, where he distinguished himself by important researches on colors. In 1826 he became a member of the academy of sciences, and in 1830 succeeded Vauquelin as professor of applied chemistry in the museum of natural history. He was afterward made fellow of the royal society of London and president of the society of agriculture. In 1851 he was awarded a premium at the London industrial exhibition for the benefit his labors had conferred on industry, and in 1852 he received from the society for the encouragement of useful inventions the prize of 12,000 francs for his work *Recherches chimiques sur les corps gras d'origine animale*, which had been published in 1823, and which is yet of high value, its suggestions having given rise to the manufacture of stearine candles, and to the use of oleic acid in the preparation of wool for cloth. Another work of his, on sanitary influences, introduced the practice of charring the interior of water casks. He was a member of the international jury at the universal exhibition of 1851 in London, and of 1855 in Paris. He was appointed director of the museum of natural history for five years in 1864, and again in 1869. Besides many articles on scientific subjects in the *Dictionnaire des sciences naturelles*, the *Journal des Savants*, and other periodicals, he has published numerous works, among which are: *Leçons de chimie appliquée à la teinture* (1828-'31); *De la loi du contraste simultané des couleurs et de l'assortement des objets colorés* (1839); *Des couleurs et de leurs applications aux arts industriels à l'aide des cercles chromatiques* (1864); *Considérations sur l'histoire de la partie de la médecine qui concerne la prescription des remèdes* (1865); and *Histoire des connaissances chimiques*, the first volume of which appeared in 1866. Many of these works have been translated into various European languages. He has also contributed many important papers to scientific societies, and in 1873, at the age of 86; was still lecturing on chemistry.

CHEVREUSE, Marie de Rohan Montbazon, duchess de, a French woman celebrated for her beauty, wit, and intrigues, born in December, 1600, died at Gagny, near Chelles, Aug. 12, 1679. When scarcely 17 years old she married the duke de Luynes, grand constable of France, who died four years afterward. She next became the wife of Claude de Lorraine, duke de Chevreuse. A great friend of Anne of Austria, she incurred the hatred of Richelieu, and became so obnoxious to him that he determined to have her arrested; but, made aware of his project, she assumed man's attire, crossed the Somme by swimming, and fled to England. For years she was an exile from France, and Louis XIII. had been inspired by his minister with such fear of her uncontrollable spirit and cunning, that in his will he forbade her return to France. Anne allowed her to return, however, but the queen's coldness induced the duchess again to leave the court. Afterward she engaged in new plots against Mazarin, mostly acting in concert with the cardinal de Retz, and was once more compelled to leave France. Her intriguing spirit outlived her beauty, and she wandered through the Netherlands, Germany, and England, still plotting against her enemies.

CHEWINK, a name popularly given to the ground robin or towhee bunting (*pipilo erythrophthalmus*, Vieill.), from its usual note. It belongs to the family of *fringillidæ* or finches, and the genus includes several species. The chewink is about 8¾ inches long, the wing 3¾, and the tail a little over 4 inches. The upper parts generally, head and neck all round, and

Chewink.

upper part of breast, are glossy black, sharply defined against the pure white which extends to the vent, but is bounded on the sides and under the wings by light chestnut; wings and tail black marked with white; iris red, as the specific name implies. The bill is stout and curved, the feet large with strong curved claws, and the tail considerably longer than the wings. The female is brown where the male is black. It is a common bird in America east of the Missouri, generally seen upon the ground among low bushes; its song is sweet and mellow. The nest is on the ground, in a small hole made for

the purpose, and the four to six eggs are pale flesh-colored, with dark spots. Two or three broods are raised in a season. Similar species are found west of the Rocky mountains, in California, and in Mexico. The food consists of worms and insects, in the search for which it seems so entirely absorbed that it may be very closely approached. It goes south in October, returning in the spring.

CHEYENNE, a S. W. county of Nebraska, bounded W. by Wyoming and S. by Colorado, and intersected by the N. and S. forks of the Platte; area, about 6,000 sq. m.; pop. in 1870, 190. The Union Pacific railroad runs E. and W. through the S. portion. Capital, Sidney.

CHEYENNE, the capital of Wyoming territory and seat of justice of Laramie county, situated on the Union Pacific railroad, in the S. E. part of the territory, 516 m. by rail W. of Omaha, Neb., and 1,260 m. E. of Sacramento, Cal.; pop. in 1870, 1,450; in 1873, about 2,500. The city is built on a broad open plain, about 6,000 ft. above the sea; Crow creek, an affluent of the South Platte, winds around it on two sides. The land rises slightly toward the west, while toward the east it gradually though imperceptibly declines. The streets are broad, and laid out at right angles with the railroad. The Denver Pacific railroad connects it with Denver, Colorado, 106 m. distant. Fort D. A. Russell is situated 2½ m. N. W. of Cheyenne, and Fort Russell depot about half way between them. The depot is used for storing and distributing the government supplies for Forts Laramie and Fetterman on the North Platte and the Indian agencies N. of the city. About 10,000,000 lbs. of freight are annually sent to those points from the Union Pacific railroad at Cheyenne. The principal public building is the brick court house, with an iron jail and jailer's residence attached, which cost \$40,000. The two-story brick public school house cost \$12,000, and has an average attendance of 70 scholars. There are about 60 business houses, representing the ordinary branches of trade. The principal manufactures are of saddles and moss agate jewelry, the stone being found in large quantities in the territory. The machine and repair shops of the Union Pacific railroad are extensive. The first national bank of Cheyenne has a capital of \$100,000. There are several hotels, a small theatre, two newspapers issuing daily and weekly editions, and Congregational, Episcopal, Methodist, Presbyterian, and Roman Catholic churches.—Cheyenne was settled in the summer of 1867, when the Union Pacific railroad first reached the point. At one period there were 6,000 inhabitants in the place and vicinity, but as the road was extended west the floating population migrated with it. In the fall of 1869 a considerable portion of the business part of the city was burned, involving a loss of \$500,000, but it was speedily rebuilt.

CHEYENNES, a nation of Indians, being with the Blackfeet the most westerly tribe connected with the great Algonquin family. They

were formerly settled on the river Chayenne or Cayenne, a branch of the Red river of the North, from which they were driven by the Sioux. They then retreated beyond the Missouri below the Warreconne, where their fortifications were long visible. Before the commencement of the present century they were driven west to the Cheyenne river near the Black Hills, and here they were found by Lewis and Clarke in 1803. Acquiring horses, they became prosperous and active, carrying their raids as far as New Mexico. In 1822 their numbers were estimated at 3,250. In 1825 Gen. Atkinson made the first treaty with them at the mouth of Teton river, establishing friendship and regulating trade, but fixing no limits. They were then at peace with the Sioux, and warring with the Pawnees, Kansas, and other tribes. Dissensions arose, and the nation separated, one part remaining with the Ogallala Sioux, and with them wresting Powder river and Tongue river valleys from the Absarokas or Crows; the other moving south to the Arkansas, where they joined the Arapahoës. In 1847 they were estimated at 5,300. By the treaty of Fort Laramie in 1851 the northern Cheyennes agreed to allow roads to be run through their territory, and arrangements were also made with the southern band. Other treaties followed, often hastily made and imperfectly understood by the Indians, to whom they were explained through a Sioux interpreter, and never fully carried out by the United States government. The multiplicity of treaties and constant change of plans excited distrust in the minds of the Indians and led to many troubles. The failure to carry out the treaty of 1861 caused a bad feeling, and hostilities were begun by the attempt of some United States troops to disarm a southern Cheyenne party in consequence of a vague complaint that animals had been stolen. The Cheyennes were for the first time arrayed against the whites, but negotiations were on foot when Col. Chivington of Colorado, Nov. 29, 1864, attacked the Sand Creek village and massacred about 100 Cheyennes, men, women, and children. The war that followed is said to have cost the government \$30,000,000, and some accounts say \$40,000,000. Since that time there has been constant trouble. Treaties were made in 1865 and 1867, each giving different limits. In 1865 the southern band, except a part known as the Dog Soldiers, agreed to go on a reservation. In 1867 Gen. Hancock burned the village of these last on Pawnee fork, and another war began, in which Gen. Custer defeated them at Washita, killing Black Kettle and 37 others, two thirds women and children. This war cost the lives of 300 soldiers and settlers. The northern band continued peaceable, although urged by the Sioux to join them against the whites in 1865. In fact these Cheyennes submitted to insults hard for an Indian to bear, and gave warning to the troops. They renewed treaties of peace in 1866 and 1868. The

Cheyennes are now (1873) in three bodies in all cases mixed with Arapahoës, on Milk river, Montana, on the North fork of the Canadian, and a small band apart.—In person the Cheyennes are a fine race, exceeding in stature all the tribes of the plains except the Osages. They are generally rich in horses and are great horse dealers. The attempts to educate them have not met with much success, the school report of 1871 showing only eight pupils, although the tribe must number 3,500 souls. Their language is extremely difficult to learn.

CHEYNE, George, a British physician, born in Scotland in 1671, died at Bath in 1743. He was intended for the church, but devoted himself to medicine, and gained a high reputation by his writings, of which he published a great number. His most popular work was a treatise on the "English Malady," that is, on spleen, vapors, hysterics, and hypochondriacal diseases in general, with a minute account of his own case (London, 1733).

CHEYNELL, Francis, an English clergyman, born in Oxford in 1608, died at Preston, Sussex, in 1665. He entered Oxford university in 1623, and at first took orders in the church of England, but in 1640 sided with the parliament, and in 1643 was made one of the assembly of divines. In 1646 he was one of the delegation to convert the university of Oxford to the parliamentary cause, and in 1648 took forcible possession of the Lady Margaret professorship of theology in that university, and also of the presidency of St. John's. But, unable to retain them, he retired to the living of Petworth, where he remained until the restoration. Cheynell had previously published a work entitled "The Rise, Growth, and Dangers of Socinianism," in which he had violently accused Chillingworth, Archbishop Laud, and others, of Socinian tendencies. After the death of Chillingworth he published a book entitled "*Chillingworthi Novissima*; or Sickness, Heresy, Death, and Burial of William Chillingworth" (1644).

CHÉZY. I. Antoine Léonard de, a French orientalist, born at Neuilly, Jan. 15, 1773, died in Paris, Sept. 3, 1832. In 1798 he was appointed a member of the learned commission who were to accompany Bonaparte to Egypt, but was prevented from continuing in the expedition by illness, and the following year he was attached to the cabinet of oriental MSS. in the national library. In 1815 a chair of Sanskrit was created for him at the collège de France, and in 1816 he became a member of the academy of inscriptions. His most important works are: *Medjnoun et Leïla*, translated from the Persian of Jami; *Yadjanadatta Badha*, an episode translated from the *Ramayana*; and *La reconnaissance de Sakountala*, a drama of Kalidasa. This last publication, giving for the first time the text with an elegant translation, was printed at the expense of the Asiatic society of Paris. His papers in the *Journal des Savants*, the *Journal Asiatique*,

and the *Mémoires* of the academy of inscriptions are also important. Among the manuscripts which he left were a *Chrestomathie persane*, a *Chrestomathie sanscrite*, a *Grammaire sanscrite*, and a *Vocabulaire sanscrit, pracrit et français*. **II. Wilhelmine Christiane von**, a German authoress, wife of the preceding, born in Berlin, Jan. 26, 1783, died Jan. 28, 1856. She was a granddaughter of Anna Luise Karsch, and a daughter of Karoline Luise von Klenke, both authoresses. In 1799 she was divorced from her first husband, and in 1802 found an asylum in the house of Mme. de Genlis in Paris, and gradually secured a competency as a writer. She was married to M. de Chézy in 1805, and in 1810 a voluntary separation took place, after which she went to Germany, where she found an influential friend in the prince of Dalberg, and where in 1813 she displayed great zeal for the relief of wounded soldiers. The latter part of her life, during which she became blind, was spent chiefly in Switzerland. She wrote the libretto of Weber's opera *Euryanthe*, many poems and novels, besides works descriptive of French society, and a biography of her mother, which she published under the name Helmina. Bertha Borntträger has published her memoirs under the title *Unvergessenes* (2 vols., Leipsic, 1858). **III. Wilhelm**, son of the preceding, born in Heidelberg, March 21, 1806, died in Vienna, March 13, 1865. He studied jurisprudence at Munich, but devoted himself to journalism and literature, and wrote many novels, besides *Erinnerungen* (2 vols., Schaffhausen, 1863-'4).—A younger brother of Wilhelm, **MAX**, a painter, died in Heidelberg in 1846.

CHIAPAS, the southernmost state of the Mexican republic, bounded N. W. by Vera Cruz, N. by Tabasco, N. E. by Yucatan, E. and S. E. by Guatemala, S. W. by the Pacific ocean, and W. by Oajaca; area, about 17,000 sq. m.; pop. about 200,000, the greater part Indians and mestizos. It is traversed by the cordillera of the Sierra Madre, and watered by several rivers, chief among which are the Chiapas or Tabasco, rising in the mountains of Cuchumatanes in Central America, and flowing N. W. through the state and N. E. through Tabasco to the gulf of Mexico; the Usumasinta, which also rises in Central America, and flows into the gulf of Mexico by three mouths; and the Teapa. These are navigable to an inconsiderable extent. The lake of Chiapas, or more correctly Tepancuapan, in the southern part of the state, is 18 m. long and 3 m. wide, and abounds in crabs; and the Lago de los Istotes, in the same region, affords a plentiful supply of excellent fish, and is by some supposed to be the source of the Usumasinta. There are several other lakes of smaller dimensions. The ounce, puma, wild cat, a species of deer, the flying squirrel, wild hog, porcupine, ant-eater, armadillo, two species of monkey, the otter, and the black bear are common in Chiapas. Among the insects may be mentioned the tarantula, centipede, scorpion, and a few others almost equally

venomous. Among the birds are black and gray eagles, owls, peacocks, mocking-birds, woodpeckers, carpenter birds, and a great variety of small song birds. Timber suitable for all purposes is abundant; as are also annotto, fustic, logwood, dragon's blood, and other dyewoods. Cotton grows well, and tobacco, vanilla, pepper, ginger, aniseed, coffee, tea, and India rubber are produced. Jalap, sarsaparilla, colpachi (possessing properties analogous to those of quinine), and other medicinal products are found in large quantities. Indigo and cochineal are no longer produced. The manufactures are limited to the weaving of some very coarse cotton and woollen cloths, and to the distillation of *aguardiente*, or brandy, from bran, which spirit, being exempt from excise duties, is extensively consumed, especially by the indigenous inhabitants. This state is remarkable for numerous ruins of ancient cities and monuments, those of Palenque being the most noteworthy. (See **PALENQUE**.) Two stones in the shape of a tongue, about a yard long and two thirds of a yard in width, one of which has an inscription, are still standing, and are objects of adoration to the Indians. There is hardly any commerce, and there is almost an entire lack of passable roads. Capital, San Cristóbal.

CHIARAMONTE, a town of Sicily, in the province and 30 m. W. of Syracuse; pop. about 7,200. It stands on a spur of the mountain range extending between Castrogiovanni and Noto, and the former Capuchin convent commands one of the finest views in Sicily. The town has a well preserved feudal castle. The vicinity produces good wine.

CHIARI, a town of N. Italy, in the province and 15 m. W. of Brescia, near the left bank of the Oglio; pop. about 10,000. It has a handsome collegiate church and a public library, and considerable trade, especially in silk. It is surrounded by an ancient ruined wall, and many Roman remains are found.

CHIAROSCURO, an Italian word, sometimes rendered in English by the term "clear-obscure," which is used in painting to designate the distribution of the lights and shadows of a picture in such a manner that the objects may be naturally and effectively relieved from one another. It comprehends all the lights and darks of a picture, and particularly refers to their arrangement in masses on opposite sides. Correggio, Leonardo da Vinci, Giorgione, and particularly Rembrandt, were the chief masters of the art of *chiaroscuro*.

CHIAVARI, a town of Italy, in the province of Genoa, situated on the gulf and 20 m. S. E. of Genoa, at the mouth of the river Sterla, and on the Genoa and Sarzana railway; pop. about 10,000. It has narrow streets, open Gothic arcades, substantial houses of remarkable architecture, picturesque towers, and handsome churches. It contains a Franciscan convent, a hospital, an ecclesiastical seminary, a public library, and agricultural and artistic

associations. There are manufactures of lace, twist, and cabinet ware, and anchovy fisheries; and in the vicinity are good quarries of marble and slate.

CHIAVENNA (anc. *Clavenna*), a town of N. Italy, in the province and 20 m. W. N. W. of Sondrio, on the Maira; pop. about 2,500. It is situated in the midst of vineyards at the foot of the Rhaetian Alps, is surrounded by walls, and well built. The baptistery of one of its churches is remarkable for some interesting antiquities and specimens of mosaic work executed in bones. A castle, a town hall, and a hospital are the other chief buildings. The town derives its importance from its situation on the Splügen road, the great thoroughfare of trade between Switzerland and Italy, with both which countries it has an active commerce. It manufactures paper, beer, for which the town is noted, wine, amianthus cloth, pottery, and silk, the last being the staple.

CHICAGO. See **CICAGO.**

CHICAGO, the principal city of Illinois, capital of Cook county, the commercial metropolis of the northwest, and the fifth in population of the cities of the United States. It is situated on the W. shore of Lake Michigan, 18 m. N. of the extreme S. point of the lake, at the mouth of the Chicago river, 715 m. in a direct line W. by N. of New York, 590 m. N. W. of Washington, D. C., and 260 m. N. N. E. of St. Louis. Dearborn observatory, $3\frac{1}{2}$ m. S. and $\frac{3}{4}$ m. E. from the court house, is in lat. $41^{\circ} 50' 1''$ N., lon. $10^{\circ} 33' 40.8''$ W. from Washington. The site of the business portion is 592 ft. above sea level, and 14 ft. above the lake; it was originally much lower, but has been filled up from 3 to 9 ft. since 1856. It is an inclined plane, rising toward the west to the height of 28 ft., giving slow but sufficient drainage. The city stands on the dividing ridge between the basins of the Mississippi and St. Lawrence, and is surrounded by a prairie stretching several hundred miles S. W. and N. Within the city limits the W. shore of the lake extends nearly N. and S. One eighth of a mile N. of the court house a bayou, called the Chicago river, extends westward about five eighths of a mile, then divides into the North and South branches, which run nearly parallel with the lake shore about two miles in each direction. The South branch turns S. W. and then W. The river and its branches, with numerous slips, afford a water frontage of 38 m., of which 24 are improved, without including the lake front, on which an outer harbor is now (1873) in process of construction. Connected with the South branch is the terminus of the Illinois and Michigan canal, which extends to the Illinois river at La Salle. Formerly this connection was by means of a lock; but recent improvements have effected a continuous flow of water from the lake through the river into the canal. The city extends N. and S. along the lake about 8 m., and westerly from the lake about 5 m., embracing an area of about

35 sq. m. The main river and its branches divide the city into three natural parts, legally known as the North, South, and West divisions, which are connected by 33 bridges, and by two stone tunnels under the river bed. The South division embraces the territory S. of the main river and E. of the South branch, 5,363 acres; the North division comprises 2,533 acres N. of the river and E. of the North branch; while that portion of the city W. of the two branches, comprising 15,104 acres, extending from the N. to the S. extremity of the city, constitutes the West division. Great improvements have recently been made by dredging the river and constructing docks, wharves, and slips for the accommodation of vessels. The harbor, at the mouth of the river, is commodious, but has required frequent dredging and several extensions of the north pier to keep out accumulations of sand brought down by a N. E. to S. W. lake current, which have made fully 100 acres of new land on the N. side of the pier. Extending E. into the lake, on the N. side of the river, is a pier about 3,000 ft. long, at the extremity of which is a lighthouse. There is also a pier extending into the lake on the S. side of the river. Along the shore of the lake, S. of the river, extends a magnificent line of breakwater more than two miles long, constructed by the Illinois Central railroad company. The inside line of the works S. of Randolph street, for about a mile, was originally about 400 ft. from the shore; but most of that space has since been filled in, and the great union depot was built on a portion of the space thus reclaimed. Other great harbor improvements, to afford increased facilities for commerce, are now (1873) in progress. The improvement of the North Chicago dock company, begun in 1867, comprises a breakwater 500 ft. long, extending N. from the north pier. From the N. extremity of this breakwater another will run W. 1,500 ft. to the shore. The space thus closed will be devoted to commodious ship channels and docks. By means of an appropriation by congress the construction of a breakwater was begun in 1870, extending from the south pier 900 ft. E. into the lake, as far as the north pier, leaving a passage of 500 ft. between the two piers for entrance to the harbor. From the E. extremity of this breakwater another line 4,000 ft. long extends S., connecting with still another line running 3,400 ft. W. to the breakwater of the Illinois Central railroad. The basin thus enclosed comprises 275 acres, the entrance to which will be by an opening 600 ft. wide in the N. side.—The first census of Chicago was taken in 1837, when the city contained 4,170 inhabitants. The population, as reported by the federal census, has been: in 1840, 4,853; 1850, 29,963; 1860, 112,172; 1870, 298,977. Of the total population in 1870, 154,420 were of native and 144,557 of foreign birth; 295,281 were white and 3,696 colored. Of the foreigners, 52,318 were born in Ger-

many, 39,988 in Ireland, 10,027 in England, 4,197 in Scotland, 565 in Wales, 6,374 in Norway, 6,154 in Sweden, 1,243 in Denmark, 1,226 in Switzerland, 1,418 in France, and 9,648 in British America. There were 59,497 families, with an average of 5.03 persons to each, and 44,620 dwellings, with an average of 6.7 persons to each. The number of persons engaged in all classes of occupations was 112,960, of whom 533 were engaged in agriculture, 42,063 in personal and professional services, 29,806 in trade and transportation, and 40,558 in manufactures and mechanical and mining industries. According to a local estimate, the population was 334,270 in 1871, and 364,377 in 1872.—The climate of Chicago is highly favorable to comfort and health. The prevailing wind for the year, and especially during the summer, is S. W. The mean temperature for the eleven

months ending with September, 1872, was 46.7°, and the total rainfall 33.71 inches. The death rate per thousand inhabitants in 1872 was 27.6, while that of New York was 32.64, Philadelphia 25.34, Boston 30.89, Cincinnati 20.3, New Orleans 30.6, and San Francisco 16.9. The rate for Chicago, however, was higher than in any preceding year except 1866, when it was 32.22. It was 24.53 in 1870, and 21.46 in 1871.—The city is regularly laid out, with streets generally 80 ft. wide, and many of them from 3 to 7 m. in length, crossing each other at right angles. The principal thoroughfares extend N. and S. In 1872 there were 534 m. of streets, of which 94 were improved; 72 m. were paved with wooden blocks, 5 with cinders, 7 with gravel, 2 with stone, and 6 m. were macadamized. The streets are well lighted with gas and supplied with 161 m. of

Chicago before the Fire.

sewers. Chicago was formerly noted as being a city of wooden buildings and very low site. About 60 brick structures were erected previous to 1852. The bricks were made from excavations in the river and slips; 25,000,000 were used in 1854, and 50,000,000 in 1856. About the same time a beautiful stone was introduced from Athens, 20 m. distant, on the canal, since called Athens marble. It was extensively used, being nearly white, soft when cut, but hardening by exposure. In the great fire of 1871 this marble crumbled before the fury of the flames, and since then many of the business structures are built of less beautiful but more durable sandstone. Iron is now much used, and the fire limits include all the more settled portions of the city, within which no wooden buildings may be erected. After the filling-in process was undertaken, the principal buildings were raised to

the new grade, whole blocks being lifted up at once by numerous jackscrews, and kept to the required height by solid masonry laid while the buildings were in mid air above the workmen. Before the fire, a strip of land along the lake shore, from a quarter to three eighths of a mile wide and 11 m. long, embraced the finest residences of the city and the suburbs, Lakeview and Hyde Park. Nearly the whole of this section was covered with costly residences and grounds. Michigan and Wabash avenues were especially devoted to the homes of the wealthy. The business portion was in the South division, and extended from the river S. to Harrison street, embracing an area of about three fourths of a square mile. Here were nearly all the banks, the principal hotels and theatres, the leading wholesale establishments in every branch of trade, and many large manufactories, chiefly of clothing and

boots and shoes. Along the river and its branches were extensive lumber yards, with immense quantities of lumber, lath, and shingles; docks covered with coal and wood; extensive depots, grain elevators, and flouring mills; toward the north were distilleries, slaughter houses, and ship yards, and toward the south numerous packing houses. For a distance of about a mile and a half S. from the harbor were numerous railroad tracks for the accommodation of three important lines, centering in the great central depot at the foot of Lake street. W. of the junction of the two branches of the river were extensive founderies and machine shops. The principal buildings of the city having been destroyed by the fire, their renewal is now (1873) in progress. The custom house and post office will cost about \$3,500,000, and the new court house about \$2,000,000, both exclusive of the ground.—Chicago has a magnificent system of public parks, authorized in 1869, and laid out and partially improved previous to the fire, after which the work proceeded more slowly. There are six parks, aggregating nearly 1,900 acres, which are connected by a cordon of boulevards 250 ft. wide, extending around the three land sides of the city, with a drive on the lake shore. These give 33 m. of straightforward driving, besides the roadways around the park. Within the northern limits of the city is Lincoln park, containing 230 acres, with a broad front upon the lake. From the N. end of this park a boulevard $3\frac{1}{2}$ m. long extends W. to Humboldt park, which contains $193\frac{1}{4}$ acres, lying $1\frac{1}{2}$ m. N. and $3\frac{1}{2}$ m. W. from the court house. About 2 m. S. of Humboldt park, connected by a similar boulevard, is Central park, an irregular tract of land nearly a mile long from N. to S., and containing 171 acres, the middle line of which lies on Madison street, $4\frac{1}{2}$ m. from the court house. From this park the Douglas boulevard runs S. three fourths of a mile and E. seven eighths of a mile to Douglas park, which contains 171 acres. From this another boulevard runs S. $4\frac{1}{2}$ m., thence E. $4\frac{1}{2}$ m., to the northern of two parks in the South division. The South park system comprises 1,055 acres. The Northern or Western park contains 372 acres, lying between 51st and 60th streets. From the S. end of this park an avenue of great breadth extends eastward a mile to the E. division of another park embracing 593 acres, with a frontage of 1.6 m. on Lake Michigan. The South park system embraces about 14 m. of interior drives and 30 m. of walks. The scheme comprehends the extension of a pier into the lake about 1,100 ft. to protect a harbor on the south which will connect it with a series of meandering lakes in the interior. The parks of the South division are outside the city limits, in the towns of Hyde Park and Lake. The three parks near the W. limits of the city are supplied with water from artesian wells. Besides those included in this system, there are several smaller parks.—Chicago has water communica-

tion with a vast area. The lakes alone have some 3,000 m. of coast line. Steamers and vessels of the largest class trade with all ports on Lake Superior, bringing in copper and iron ores from the rapidly developing mines of that region. The Welland canal, between Lakes Erie and Ontario, admits vessels from Lake Michigan to Montreal, where they connect with steamer lines to Europe. Other canals give communication with New York and the interior of New England. It is also proposed to construct a canal for vessels of 1,000 tons burden from the head of Georgian bay to Toronto, which would materially facilitate the lake commerce of Chicago. In the summer of 1856 the *Dean Richmond* was loaded with wheat at Chicago, which she discharged at the docks in Liverpool; and several other vessels have since made direct connection with European ports; but this operation was seldom profitable, owing to the great difference between the requirements of fresh and salt water navigation. Transfer at Montreal to ocean-built vessels is found to be much cheaper; and the long cherished idea of European traffic without transfer is now abandoned. The Illinois and Michigan canal connects Chicago with La Salle, at the head of navigation on the Illinois river, which falls into the Mississippi. Work on this canal was commenced July 4, 1836, and finished in 1848, after a suspension of two years due to financial embarrassments. It is 96 m. long, with 15 locks; the highest level was 12 ft. above the lake. During 1866-'70 the canal was deepened by the city of Chicago, at a cost of \$3,251,621; the highest 26 m. being cut down to 8 $\frac{1}{2}$ ft. below the ordinary water level of Lake Michigan. This gives improved navigation, and also carries off the sewage of the city toward the Illinois river at the rate of a mile an hour, and draws with it enough water from the lake to keep the current clean. The canal is usually navigable from the middle of April to the latter part of November.—The first line of railroad (toward Galena) was commenced in 1847. In 1850 there were 42 m. of connecting line. In 1852 the city was connected with the east by the Michigan Southern in February, and the Michigan Central in May. It now has railroad communication with all parts of the continent by four trunk lines to the east, six to the west, bridging the Mississippi and connecting with the Pacific states, two southward to the gulf of Mexico and the southwestern states, and two northward to the Lake Superior region. In addition to these, with numerous branch lines and connections, a dozen other roads are now seeking admission to the city. More than 10,000 m. of railroad are directly tributary to Chicago, with annual gross receipts of nearly \$100,000,000, and annual profits of \$40,000,000; while 350 trains enter and leave daily, giving 700 arrivals and departures. The principal lines entering the city in 1873 were as follows: the Chicago and Northwestern; the Illinois Central; the Chicago, Rock Island, and

Pacific; the Chicago, Burlington, and Quincy; the Chicago and Alton; the Michigan Central; the Lake Shore and Michigan Southern; the Pittsburgh, Fort Wayne, and Chicago; the Pittsburgh, Cincinnati, and St. Louis; and the Chicago, Danville, and Vincennes. The railroad depots were formerly much scattered; but the policy of reconstruction leans toward the concentration of the railroad business into three grand union depots—one on the lake shore, one on the south side near the river, and the third in the West or North division, with a circular railroad on the outskirts, connecting all the lines that enter the city. Ample facilities for communication between different parts of the city are afforded by three lines of street railroads in the principal thoroughfares, and numerous lines of omnibuses. Until recently intercourse between the three divisions of the city was effected only by 33 bridges, which span the river at intervals of two squares, and swing on central pivots to admit the passage of vessels. These bridges, however, were a serious impediment to navigation as well as to vehicles and pedestrians. To obviate this inconvenience, a tunnel was constructed in 1868 under the South branch at Washington street, by which an uninterrupted communication was established between the South and West divisions. It is 1,608 ft. long, with a descent of 26 ft., has a double roadway for vehicles and a separate passage for pedestrians, and cost about \$400,000. In 1870 another similar tunnel, with a total length of 1,890 ft., including approaches, was constructed under the main river on the line of La Salle street, connecting the North and South divisions. Its cost was \$549,000.—Chicago is

the great commercial centre of the northwest, and in commercial importance ranks next to New York among the cities of the United States. Formerly there was but half a league of portage for canoes from Chicago river to Illinois river, which is tributary to the Mississippi; and at high water the Indians passed from one to the other without portage. This, and the fact that Chicago river was then the only good harbor near the head of lake navigation, suggested it as the terminus of a canal to connect the two great watercourses. Its commercial importance was thus established, and grew rapidly with the development of the country westward. The mercantile trade of the city is very important, as it supplies most of the region from which produce is received. In 1852 the commerce was estimated at \$20,000,000; in 1856 at \$85,000,000; in 1860 at \$97,067,617; in 1870 at \$400,000,000; in 1872 at \$450,000,000. The following were the leading items for the 12 months succeeding the fire, counting only the cost at first sale: breadstuffs, \$49,321,000; live stock, \$70,546,000; provisions received, \$9,455,000; wool and hides, \$14,818,000; tea and tobacco, \$16,526,000; lumber, &c., \$13,166,000; other produce, \$13,125,000; groceries, \$59,000,000; dry goods, \$40,000,000; boots and shoes, \$10,500,000; hardware, &c., \$9,500,000; clothing, hats, &c., \$6,000,000; jewelry, \$5,750,000; paper, &c., \$5,000,000; drugs, &c., \$5,000,000; millinery, \$4,500,000; books and newspapers, \$3,500,000; crockery, \$3,100,000; music and musical instruments, \$2,250,000; other sales, \$104,000,000. The leading articles of commerce are exhibited in the following statement of the aggregate receipts and shipments for two years:

ARTICLES.	1871.		1872.	
	Receipts.	Shipments.	Receipts.	Shipments.
Beef, bbls.	59,289	89,451	14,512	89,911

Wool, lbs.	27,026,621	24,351,524	28,181,509	27,720,089

Chicago is a port of entry, and has an extensive commerce with Canada. The total value of domestic produce exported to Canada by lake in 1872 was \$5,251,539. By the act of congress of 1870 merchandise from foreign countries may be shipped direct to Chicago by being transported in bond from the port of first entry. This enables direct shipments to be made between Chicago and foreign countries, the transfer between Chicago and the seaports of the United States being made in

bonded cars. As early as 1854 it was announced that Chicago was the greatest primary grain depot in the world, collecting more grain from the producers than even the Russian ports. Since then the city has become also the greatest grain market in the world, her produce forming the basis for speculation, as stocks and gold do in New York. The following tables show the growth and extent of the trade, flour being reduced to its equivalent in wheat in the totals:

RECEIPTS OF BREADSTUFFS.

The grain is received and shipped in bulk. It is lifted into elevators from railroad cars by buckets running on an endless chain, and operated by powerful steam machinery, and emptied through spouts into the holds of vessels. In 1873 there were 15 elevator warehouses, with an aggregate storing capacity of 12,800,000 bushels, in addition to several smaller storehouses. The capacity of the largest is 1,500,000 bushels; of the smallest, 200,000. Most of these elevators can each re-

ceive and ship 100,000 bushels per day. The business is supervised, and the grain graded, by inspectors appointed by the state, and an accurate record of receipts and shipments is kept by a state registrar. Of the total receipts in 1872, 8,017,865 bushels came by the Illinois and Michigan canal, 173,971 by lake, and the remainder, nine tenths of the whole, by railroad. The various lines by which the grain is sent to market are indicated in the following statement of shipments for 1872:

SHIPPED BY	Flour, barrels.	Wheat, bushels.	Corn, bushels.	Oats, bushels.	Barley, bushels.
Lake—

Total.....	1,751,682	14,014,780	50,479,724	15,800,288	5,778,679

There were also shipped 1,429,076 bushels of rye, chiefly by railroad. In 1872, 563,617 bushels of wheat and 388,970 of corn were shipped direct to foreign countries, chiefly to Great Britain and Ireland, on through bills of lading.—The total number of vessels owned in the district of Chicago in 1872 was 654,

with an aggregate tonnage of 99,403. Among these were 268 schooners, 245 canal boats (including 17 propelled by steam), 54 tugs, 34 scows, 31 barks, 8 propellers, 7 barges, 6 brigs, and 1 steamer. The number of arrivals and clearances for a series of years has been:

YEARS.	ARRIVED.		CLEARED.

1865.....	10,112	2,106,859	10,067	2,092,276
1866.....	11,084	2,258,572	11,115	2,361,520
1867.....	12,230	2,588,527	12,140	2,512,676
1868.....	13,174	2,984,591	13,225	3,020,812
1869.....	13,730	3,123,400	13,872	3,149,946
1870.....	12,739	3,049,265	12,933	2,988,942
1871.....	12,330	3,096,101	12,812	3,082,235
1872.....	12,824	3,059,752	12,581	3,017,790

In 1872, 12,622 vessels in the coasting trade, of 3,001,538 tons, arrived, and 12,064 cleared; 152 foreign vessels, of 43,802 tons, arrived from and 150 cleared for foreign ports; 50 American vessels, of 14,412 tons, arrived from and 317 cleared for foreign ports.—As a market for live stock Chicago is the most important centre in the United States. The vast live stock trade is transacted at the union stock yards, situated near the S. limits of the city, and connected with all the railroad lines. They were opened Dec. 25, 1865, comprise 345 acres, of which 100 are in pens, and have 31 m. of drainage, 7 m. of streets and alleys, 3 m. of water troughs, 10 m. of feed troughs, 2,300 gates, and cost \$1,675,000. They have capacity for 21,000 cattle, 75,000 hogs, 22,000

sheep, and 200 horses. Water is supplied for the use of the yards from artesian wells. The foregoing tables exhibit the receipts and shipments of cattle and hogs for a series of years. The total value of the live stock received in 1872 was estimated by the board of trade at \$75,475,000, including cattle valued at \$41,000,000, hogs \$33,500,000, sheep \$950,000, and horses \$250,000. Since 1862-'3 Chicago has held the supremacy in extent of pork-packing, having in that year distanced Cincinnati in this respect. Of the total number (4,885,910) of hogs packed in the west in 1871-'2, 1,225,236 were packed in Chicago and 717,816 in Cincinnati. The growth of this industry in Chicago is shown in the following statement:

SEASON.	Number of Hogs Packed.	SEASON.	Number of Hogs Packed.
1851-'52.....	22,036	1862-'63.....	970,264

The packing of 1872 was performed by 27 principal firms and a number of small houses. One firm alone packed 373,725 hogs in the four winter months. The work is very expeditious. The hogs are driven up an inclined plane to a pen in the upper part of the packing house. A chain or cord attached to a pulley in a sliding frame near the ceiling is slipped over one hind leg, the hog is jerked up, his throat cut, the body lowered into a long vat of boiling water, lifted out, scraped, disembowelled, and hung up to cool. When cooled the bodies are cut up into "meats" or pork, and salted, the irregular pieces being thrown into huge tanks, where they are steamed into lard. A

large proportion of the product is shipped to Europe during the winter months. Beef packing is also an important branch of trade, but there has been a decline in this industry in consequence of the increase in the number of cattle packed in the southwest where they are raised. The number of cattle packed in 1860 was 51,606; the maximum (92,459) was reached in 1865. Since that date the number has decreased, being 21,254 in 1871, and 16,080 in 1872. The following statement exhibits the details of this business for four years, the packing being done chiefly by four packers:

	1868-'9.	1869-'70.	1870-'1.	1871-'2.
Cattle packed.....	26,950	11,963	21,254	16,080

—The lumber trade of Chicago is a very prominent item of its commerce. The city takes a very large proportion of the produce of Michigan and Wisconsin, and distributes it by railroad and canal all over the northwest, much of it being manufactured in the city before shipment. The following are the statistics of this commerce for several years:

YEARS.	RECEIVED.		SHIPPED.	
	Lumber, feet.	Shingles, number.	Lumber, feet.	Shingles, number.
1852...	147,816,232	77,090,500	70,740,271	55,851,088

The lumber trade is transacted by a lumber exchange, while the transfer of other produce is chiefly effected by the board of trade. The stock of lumber on hand Jan. 1, for three years, has been:

KINDS.	1873.	1872.	1871.

—In 1850 the manufactures of Cook county, of which Chicago forms nearly all, were returned at \$2,562,583, on a capital of \$1,068,025, employing 2,031 hands. In 1860 the productions were worth \$13,555,671; capital, \$5,571,025; hands, 5,593. In 1870, and for the years succeeding the fire, the values of products of Chicago alone were as follows:

PRODUCTS.	1870.	Oct. 9, '71, to Oct. 9, '72.
Pork packing.....	\$13,000,000	\$13,650,000

Total.....	\$76,843,000	\$103,470,000
Add buildings.....	12,000,000	44,100,000
Total.....	\$88,843,000	\$147,570,000

The manufactures of 1872 include 353,000,000 bricks, and \$6,500,000 worth of iron, Bessemer steel rails, sheet iron, and boiler plate. The iron manufacture employs 1,200 men in four establishments, which in 1872 used 100,000 tons of ore, mostly from Lake Superior, 300,000 tons of bituminous coal and coke, and 25,000 tons of charcoal iron, on an aggregate working capital of \$4,500,000. Chicago produced more Bessemer steel in 1872 than any state outside of Illinois, except Pennsylvania; and the iron industry promises to become much more important in the future. Prior to the great fire the manufacture of flour was extensively carried on. There were then 15 mills, which produced 732,479 barrels of flour in 1868, 543,285 in 1869, 443,976 in 1870, and 327,739 in 1871. In the last named year six of them were destroyed by fire, and the remainder produced 186,968 barrels of flour in 1872. The manufacture of highwines has increased from 3,744,000 gallons in 1860 to 7,082,364 in 1870, and 7,209,347 in 1872. There are also manufactures of cotton and watches. About 50,000 persons are employed in manufactures, and nearly one third of the commerce of the city is based upon the productions of these workers. The manufacturing business is yet in its infancy, except in agricultural implements, pork and meats, boots and shoes, and leather, for which the city is famous. Ship building is carried on to some extent. During the year ending June 30, 1872, six sailing vessels of 926 tons and two barges of 193 tons were built in Chicago. The banking business of Chicago is enormous. The first bank

was a branch of the second of the state of Illinois, established in Chicago in December, 1835; it suspended specie payments in 1837, and closed in 1841. The next was established in 1853. At the close of 1872 there were 21 national banks, with a total capital and surplus of \$11,044,885, and \$23,060,507 deposits. There were also 18 savings banks (some being connected with other banks), with \$12,013,000 deposits; 8 state-chartered commercial banks, with capital and surplus of \$2,926,000, and \$3,055,627 deposits; one foreign branch bank, and numerous private banks.—Chicago is divided into 20 wards. The government is vested in a mayor, chosen every two years, and a board of 40 aldermen, two from each ward, also elected for two years. The mayor has little power beyond the veto, and makes nominations to be confirmed or rejected by the council. The board of supervisors is a county organization, to which one member from each ward and two from each division of the city are elected. The board of fire and police commissioners consists of three members, elected by the people, and has full authority over the fire and police departments. The board of public works consists of three members, nominated by the mayor and confirmed by the council; they have control of the streets, public buildings (except schools), bridges, &c., with power to make assessments on property, subject to the approval of the council. The board of education comprises one member from each ward, appointed by the council; they have charge of school buildings, appointment of teachers, choice of text books, and general school regulations. Sanitary regulations are intrusted to a board of health and a sanitary superintendent. There are two boards of park commissioners. Besides the county courts, there are three police courts, one for each division. The United States circuit and district courts for the northern district of Illinois are also held here. The police force consists of a superintendent, 3 captains, 16 sergeants, and about 500 patrolmen. For police purposes the city is divided into 12 precincts. The total number of arrests during the year ending March 31, 1872, was 21,931; value of property reported stolen, \$64,449, of which \$40,187 was recovered; total amount of fines, \$123,475. The charges on arrest were: assault with a deadly weapon, 242; burglary, 160; drunk, 4,397; drunk and disorderly, 3,700; disorderly, 5,684; forgery, 26; highway robbery, 22; keeping disorderly house, 135; keeping gaming house, 63; keeping house of ill-fame, 302; larceny, 2,123; murder, 3; riot, 141; robbery, 157; vagrancy, 881. The nationalities of those arrested were: 8,167 Irish, 7,646 American (including 652 colored), and 3,379 German. The cost of the department during the year was \$498,247, of which \$229,652 was for salaries. The fire department comprises a force of 201 men, including officers, fire wardens, and the

fire alarm telegraph corps. The apparatus in use includes 16 steam fire engines with an attending hose cart to each, and 26,150 ft. of rubber and 9,100 ft. of leather hose. The apparatus used for elevating hose can be raised to the height of 84 ft. without contact with any building or other support. It is used for the purpose of elevating firemen with hose to the upper stories of high buildings, in order to throw a stream more effectively upon a fire, and to save life and property. The estimated value of property in use, including real estate, is \$639,050. During the year ending March 31, 1871, there were 489 fires and 44 false alarms. The total amount of loss was \$972,800; amount of insurance, \$745,000; total amount of insurance on property more or less injured by fire, \$1,246,224. These figures do not include the great fire, an account of which is given hereafter. In the preceding year there were 669 fires, with losses amounting to \$2,447,845; insurance, \$2,183,498; total amount of insurance on property injured by fire, \$4,416,690. There is a very efficient fire alarm and police telegraph system, established in 1864, and much improved since the fire, having in 1872 234 signal boxes in different parts of the city, each connected by electric wire with the police stations and engine houses. The expenses of the fire department for 1872 were \$512,520.—The system of water supply for Chicago has been called one of the wonders of the world. A nearly cylindrical brick tunnel, 62 inches high and 60 wide, extends two miles under the lake, lying 66 to 70 ft. below the lake surface. The water descends through a grated cylinder enclosed in an immense crib, on which a lighthouse is to be constructed. At the shore end it is pumped up an iron column 130 ft. high, inside a stone water tower, and thence flows to all parts of the city. The engines can pump 72,000,000 gallons daily, and the tunnel can deliver 57,000,000 gallons daily. The tunnel was commenced March 17, 1864, and finished Dec. 6, 1866. Water was first supplied to the city through it March 25, 1867; it is always pure, and the supply has never been interrupted except a few days by the great fire. The city is now (1873) constructing another tunnel 7 ft. in diameter to the same crib, to extend under the city, to give an independent supply to the southwestern quarter. An abundant water supply has recently been also developed in artesian wells, of which there are now about 40. The depth varies from 650 to 1,646 ft., the lowest reaching the sandstone. The flow averages about 200 gallons per minute, and no diminution is observed from sinking adjacent wells. The water is variously supposed to come from Rock river and from the region of the Mississippi; it is reasonably pure, containing 70 grains of solid matter per gallon, while lake water has 8 grains. It is chiefly objectionable because it contains 24 grains of sulphuric acid, while lake water has less than one third of a grain. In 1872 there

were 309 m. of supply pipes and 1,667 fire hydrants. The amount of water daily supplied in 1872 was 23,464,877 gallons, or 72·8 to each inhabitant. The total cost of the water works to Jan. 1, 1873, was about \$5,225,000. A site for the new water works, consisting of 3½ acres of land, has been purchased in Ashland avenue, near 22d street. A tunnel 7 ft. in diameter and 4 m. in length will pass under the central portion of the city, connecting the old and the new works. It will be capable of conveying 100,000,000 gallons of water daily, and will afford a central supply of water for use in case of fire, independent of that furnished by the pumps and water mains.—The bonded debt of Chicago, Jan. 1, 1873, was \$13,546,000. The receipts into the treasury for the year ending April 1, 1872, amounted to \$12,936,581, and the expenditures to \$14,112,957. The chief items were :

	Receipts.	Expenditures.
Board of public works appropriation	\$269,969	\$983,529
Certificates of debt.....	252,703	83,985
Fire department.....	146,598	352,660
Interest fund.....	131,328	258,097
Lamp districts.....		169,140
Licenses.....	187,631	2,385
Police fund.....	228,402	490,685
River improvement fund.....	488,264	669,956
School tax fund.....	54,974	462,136
Sewerage fund.....	3,309,273	3,600,772
Sewerage tax fund.....	3,021,234	3,119,839
Special assessments.....	1,397,299	1,887,312
Taxes.....	2,209,953	
Tunnel fund.....	94,743	180,963
Water fund.....	655,960	774,836
Water tax fund.....	111,645	322,942

The total valuation of real and personal property in the city for the purposes of taxation, with the amount and rate of taxation and the bonded debt, has been as follows :

YEAR.	Total Valuation.	Rate of Taxation per ct.	Total Tax Levied.	Bonded Debt.
1841...	1,667,445	6-10	10,004
1842...	1,530,213	6-10	9,181

The actual value of property in 1871 was about \$620,000,000.—The public school system takes high rank for efficiency; it gives instruction to the children of citizens free of charge. The total number of schools in 1872 was 32, including 1 high, 1 normal, 19 grammar, and 11 primary schools. These occupied 45 buildings and 412 rooms. There were 476 teachers, of whom 445 were females. According to the school census of 1872, the school population, including those between 6 and 21 years of age, was 88,219. The whole number of different pupils enrolled was 38,035. The average number belonging to the high school was 512; normal, 63; grammar and primary schools, 23,964; total 24,539. The course of study in the high school is four years. Of the 476 teachers employed in 1872, 221 were graduates of the normal and high schools. German and music are extensively taught in the public schools, the number of pupils studying the former in 1872 being 4,533. The total amount expended for the support of schools was \$479,349, including \$359,588 for teachers' salaries. The total cost for each pupil, including 6 per cent. valuation upon school property, was \$15 97 on the number of pupils enrolled, \$24 75 on the average number belonging to the schools, and \$26 41 on the average daily attendance. The total income for school purposes amounted to \$395,289, including \$303,802 from school tax fund (at the rate of 2 ⁴/₁₀₀ mills per dollar), \$30,487 from state fund, and \$61,003 from rents and interest. The value of school buildings was \$1,071,100; land, \$1,194,452. There are also many private academies, and several schools sustained by the Catholics. The Baptists, Methodists, Presbyterians, Congregationalists, and Roman Catholics have flourishing colleges and institutes for training ministers, all moderately well endowed, but suffering heavily from the fire. The Baptist denomination is identified with the university of Chicago, founded by the efforts of and partially by gift from Stephen A. Douglas. Connected with it are a very efficient law institute and the Dearborn observatory, which contains a very fine equatorially mounted refracting telescope, of 23 feet focal length and 18½ inches aperture, made by Alvan Clark and sons, and set up in 1864, then being the largest and best in the world. The city also contains six medical colleges, one of which is open to women. The academy of sciences, established in 1857, lost a valuable collection of 18,000 specimens by fire in 1866, and again lost all in 1871, though in a "fire-proof" building. It is now in a new building, and is slowly gathering a new museum and library. The Chicago historical society, established in 1856, lost in the fire 60,000 bound volumes and 150,000 pamphlets, besides files of newspapers, valuable MSS., fine paintings, and numerous war relics. It has not been revived, but its place is being taken by a public library, the nucleus of which was con-

tributed by English authors and publishers in 1872. It will occupy the custom house and post office of 1871, the walls of which were left standing. The Christian union has a library, reading room, gymnasium, &c., and evening classes in languages, art, and science; the total expense to each member being \$1 per year. The young men's Christian association, organized March 28, 1858, will probably soon erect a new building, to take the place of their magnificent Farwell hall, burned down in 1871.—The newspaper press of Chicago has wide circulation and influence. The first was the "Democrat," established in 1833 by John Wentworth, which in 1861 was merged in the "Tribune," established in June, 1847, originally whig, afterward republican, now free-trade independent. The "Evening Journal," protectionist republican, was established in 1844; the "Times," free-trade democratic, in 1854; the "Evening Post," free-trade republican, in 1865; the "Inter-Ocean," protectionist republican, in 1872, succeeding the "Republican;" the "Evening Mail," independent, in 1869; and the *Staats-Zeitung*, German, republican, in 1846. There are two other German dailies, several secular weeklies, four religious weeklies ("Advance," "Interior," "Northwestern Christian Advocate," and "Standard"), one scientific, three literary, and several medical monthlies. The total number of dailies, weeklies, and monthlies is about 80, not including mere advertising sheets, programmes, and circulars.—Since 1860 the city has been a prominent art centre. Several galleries and the academy of design were burned in 1871; the latter will be re-established. Before the fire Chicago was liberally supplied with places of amusement. Of first-class theatres, McVicker's and Hooley's are rebuilt; Aiken's, the academy of music, and Myers's are new. The magnificent opera house, erected in 1864, and the museum, in 1863, had not been reproduced in 1872. The board of trade is an influential commercial body of nearly 1,400 members, organized in 1850. It meets daily in the chamber of commerce. Chicago had three taverns in 1830, and not less than four hotels in 1835; the oldest now existing is the Tremont, built in 1834. Since then the city has been noted for the extent of its hotel accommodations. Nine extensive hotels have been rebuilt since the fire, at a cost of more than \$8,000,000, which, with 12 or 15 smaller ones, more than restore the original accommodations for travellers. All are much superior in appearance and comfort to those destroyed, most of them containing fewer rooms and better furniture.—The following countries are represented by consuls in Chicago: Austria, Belgium, Denmark, France, Germany, Great Britain, Italy, the Netherlands, Sweden, and Switzerland.—Chicago, almost equally with Brooklyn, is entitled to be called a city of churches. The Methodists were the pioneers in worship. They were

represented there by the Rev. Jesse Walker; the first quarterly meeting was held in the autumn of 1833, and the first regular class was formed the following spring. The first Presbyterian church was organized June 26, 1833, with the Rev. Jeremiah Porter as pastor, 25 members from the garrison and 9 citizens. Other churches began as follows: Baptist, Oct. 19, 1833; Roman Catholic (built), 1833-'4; Episcopal, 1834; Unitarian, 1836; New Jerusalem, 1843; Jewish, 1847; Universalist, 1850; Congregational, 1851. The following were the structures the day before the fire; the congregations were widely scattered by the calamity, but most of the church edifices destroyed have since been rebuilt, and the membership is probably greater now than then: Baptist, 20 churches, 8 missions; Christian, 4 societies, 2 churches; Congregationalist, 13 churches, 2 missions; Episcopal, 15 churches, 4 missions; Evangelical, 17 churches; Independent, 1 church, 5 missions; Jewish, 5 synagogues; Lutheran, 6 churches, 1 mission; Methodist, 21 churches; Presbyterian, 19 churches, 8 missions; Roman Catholic, 25 churches, 12 convents and schools; New Jerusalem, 2 churches, 2 missions; Unitarian, 3 churches and one other society; Universalist, 3 churches and a fourth society; Friends, 2 societies; miscellaneous, 4 churches. Total, 156 structures, a large proportion of which were fine stone edifices, 36 Protestant missions or societies not owning buildings, and 12 Catholic convents or schools. Total attendance, 150,000; number of Sunday school scholars, 57,000; value of church property, with lands, \$10,350,000, or an average of \$69 to each attendant on church worship.—Long before the site of Chicago was visited by a white man, it was a favorite rendezvous for several Indian tribes in succession. The earliest recorded were the Tamaroas, the most powerful of many tribes of the Illini (whence the name Illinois). The word Chicago is Indian, probably corrupted from *Cheecagua*, the name of a long line of chiefs, meaning "strong;" also applied to a wild onion that grew plentifully on the banks of the river. The first geographical notice occurs in a map dated Quebec, Canada, 1683, as "Fort Checagou." It was first visited by Marquette, a French Jesuit missionary, in 1673, who returned and camped near the site during the winter of 1674-'5. It was visited about the same time by Joliet, and subsequently by Hennepin and La Salle, and other French explorers. The first fort was probably built by the French, and abandoned when Canada was ceded to Great Britain. Fort Dearborn was built in 1804 by the United States government, on the south bank of the river, near its mouth. When the war with Great Britain broke out in 1812, the government ordered the fort to be abandoned, fearing it could not be held. On Aug. 15 Capt. Heald marched out with the garrison and others, and when a mile and a half from the fort he was

attacked by the Pottawattamie Indians, who killed 26 regulars, 12 militiamen, 2 women, and 12 children, and then destroyed the fort. In 1816 Capt. Bradley rebuilt the fort, which was occupied by the United States till 1837, and then abandoned, as the Indians had removed beyond the Mississippi Oct. 1, 1835. The fort was demolished in 1856, but one of the outbuildings remained till it was burnt down in the great fire. On March 2, 1827, congress granted to Illinois every alternate section of land on each side of the line of the proposed Illinois and Michigan canal, to aid in its construction, to connect Chicago with the head of navigation on the Illinois river. On Jan. 22, 1829, the state organized a board of canal commissioners, with power to lay out towns along the line. Under them James Thompson surveyed the town of Chicago, his

first map being dated Aug. 4, 1830; it embraced an area of three eighths of a square mile. In 1831 it contained about 12 families, besides the garrison in Fort Dearborn. The town of Chicago was organized Aug. 10, 1833, with 5 trustees; it contained 560 acres, 550 inhabitants, 29 voters, 175 buildings, and property valued at \$60,000; the taxable valuation was \$19,560, and the first year's taxes were \$48 90. On Sept. 26, 1833, 7,000 Pottawattamies assembled there in council, and signed a treaty to remove beyond the Mississippi; they ceded some 20,000,000 acres to the United States for \$1,100,000. Chicago was incorporated as a city March 4, 1837. The first election under the charter was held May 1 following, when W. B. Ogden was chosen mayor. The first census was taken July 1, 1837, when the city contained a population of 4,170. The

Chicago after the Fire. (Scale, 1 inch to the mile.)

rapid growth of Chicago in population and commercial importance is without a parallel; while the energy of the citizens is attested by the many gigantic public improvements that have been successfully completed at immense cost.—In October, 1871, Chicago was the scene of one of the most destructive conflagrations of modern times. There had been several unusually large fires on previous days, but on Sunday evening, Oct. 8, the great fire originated in a small wooden barn in De Koven street, in the southern part of the West division, near the river, from the upsetting, as is supposed, of a lighted kerosene lamp. The buildings in that quarter were mostly of wood, and there were several lumber yards along the margin of the river. Through these the flames raged with great fury, and were carried across the South branch by the strong westerly wind then prevailing, and thence swept into the South

division, which was closely built up with stores, warehouses, and public buildings of stone, brick, and iron, many of them supposed to be fire-proof. The fire continued all day Monday, and crossed the main channel of the Chicago river, sweeping all before it in the North division, which was occupied mostly by dwellings. The last house was not reached till Tuesday morning, and many of the ruins were still burning several months afterward. The total area burned over, including streets, was 2,100 acres, or nearly $3\frac{1}{2}$ sq. m.; number of buildings destroyed, 17,450; persons rendered homeless, 98,500; killed, about 200. Among the buildings were the court house, custom house and post office, chamber of commerce, gas works, 3 railroad depots, 9 daily newspaper offices, 32 hotels, 10 theatres and halls, 8 public schools and several branches, 41 churches, 5 elevators containing 1,642,000 bushels of

grain, and all the national banks but one. The loss on buildings was \$50,000,000, and on personal property and merchandise \$140,000,000; total, \$190,000,000, of which about \$44,000,000 was recovered on insurance. Including depreciation of real estate and loss to business in consequence of the fire, the grand total of pecuniary damage has been estimated at over \$200,000,000. The property in the city before the fire was valued at \$620,000,000; the loss, therefore, was about one third of the entire property. The total losses by insurance companies amounted to \$96,533,721 of which about \$6,000,000 was sustained by foreign companies, and the remainder by companies of the United States. In consequence of their losses 57 of these companies were forced to suspend payments. The suffering occasioned by the fire was very great, and elicited prompt expressions of sympathy and offers of material aid from all parts of the United States, and from various cities of Europe. A relief and aid society was immediately formed to receive and distribute the supplies and funds contributed. According to a report of the society, published Nov. 7, about one month after the fire, \$3,500,000 had then been subscribed, of which \$2,050,000 had been paid; the society was then aiding 60,000 persons. The legislature of Illinois was promptly convened in extra session, and adopted measures of relief for the city. The whole amount contributed in money, provisions, and clothing for the relief of the sufferers reached nearly \$7,000,000. The business of the city was paralyzed but a short time. Before winter many merchants were doing business in extemporized wooden structures, and the rest in dwellings; while the sufferers who could not procure other homes were cared for in board barracks. In a year after the fire a large part of the burnt district had been rebuilt, at an expenditure of \$40,500,000, and \$4,000,000 worth of buildings were erected outside the fire limits; while the mercantile business and produce movements were much larger than ever before. The work of rebuilding is now (1873) advancing almost as rapidly as in 1872; and scarcely a trace of the disaster will be left in three years from the date of the occurrence, except in the improved character of the new buildings over those destroyed.

CHICCORY, or **Succory** (*cichorium intybus*), or the wild endive, a plant belonging to the same family as the dandelion, found growing wild in most parts of Europe, and in England in great profusion. It is also naturalized in this country, and is seen in the fields and roads along the fences in neighborhoods long settled. It blossoms in August and September, and may be easily recognized by its bright blue flowers. In its natural state the stem rises from 1 to 3 ft. in height, though under cultivation it may be brought to a height of 6 ft. The root is fleshy and milky. Chicory was formerly used to a considerable extent for medicinal purposes, and is still thought by

some to be beneficial, if taken freely, in the early stages of jaundice and visceral obstructions, &c. It is employed almost exclusively of late as a substitute for coffee, or in the adul-

Chicory.

teration of this article. When prepared for this purpose, the roots are dried and reduced to powder, which resembles in color ground coffee, but it has neither the essential oil nor aromatic flavor of coffee. Its cheapness recommends it to the poor, and the beverage is by no means unpleasant. Large crops of chicory are raised in England for the acknowledged purpose of adulterating coffee, and the sale of this mixed article is legalized, under the proviso that each package be labelled "Mixture of Coffee and Chicory." By chemical analysis, it has been found that chicory possesses few elements in common with coffee, and contains very little of the nutritive properties of which so high an opinion is sometimes entertained. In cases where it is used for a long time its effects are often deleterious, especially upon the nervous system. Notwithstanding the great cheapness and abundance of chicory it does not escape adulteration. The substances used for this purpose are roasted wheat, rye, acorns, carrots, and a variety of similar articles, and even, it is said, exhausted tar, or "croats," and oak-bark powder.

CHICHEN, or **Chichen Itza**, an ancient city of Mexico, in the state and peninsula of Yucatan, about 35 m. S. W. of Valladolid; lat. 20° 15' N., lon. 88° 30' W. Notwithstanding the appearance of great antiquity of these ruins, which are perhaps the most remarkable in all Yucatan, they are in a better state of preservation than any others; but they have the distinguishing feature common to all of them, namely, the impossibility of ascertaining the purpose or uses of the extraordinary structures which still stand in testimony of the high degree of civilization of a people long since forgotten. According to Stephens, the most curious and at the same time the most incomprehensible ruins he had met with were a series

of columns at Chichen, the highest of which do not exceed 6 ft., so disposed as to form a vast parallelogram, each row being 3, 4, and 5 ft. deep from the outside to the enclosed space

Chichen.

within. In the immediate vicinity of the area comprised within these pillars is the *castillo* or castle, rising from the same plane, and occupying the top of a lofty pyramidal mound which measures at its base on the N. and S. side 196 ft., and on the E. and W. side 202 ft., and is 75 ft. in height. The four sides of the building itself measure 43 and 49 ft. respectively in the same directions as the mound.

CHICHESTER (anc. *Regnum*), a city of England, capital of the county of Sussex, at the termination of a gentle slope from the South Down hills, 53 m. S. W. of London, and 14 m. E. N. E. of Portsmouth; pop. in 1871, 8,205. It is surrounded by an old but well preserved wall $1\frac{1}{2}$ m. in circuit, lined with elms, and forming a pleasant walk. There are four main streets radiating from a central square, where there is an elegant cross, erected in 1478. Most of the houses are of brick with tiled roofs, and many are built with considerable taste. The principal edifice is the cathedral, erected in the 13th century, upon the foundations of one erected in 1108, and exhibiting specimens of nearly every style of Gothic architecture. The beautiful octagonal spire, 300 ft. high, built in the 14th century, fell down in 1861, in consequence of some repairs which were in progress, and a new one was erected in 1866. One of its most striking features is a monument to the poet Collins, who was born and died in this city. It has eight other modern monuments by Flaxman, and many more of some antiquity. The extreme length of the cathedral is 407 ft., and its breadth 150 ft. The transept is 129 ft. long by 34 ft. broad. Near the N. W. angle is a massive bell tower, 120 ft. high, and on the S. is a quadrangle enclosed by cloisters and containing the churchyard. There is a blue coat school founded in 1702 and enjoying an income from endowment of £1,800 per annum. There are also a diocesan

theological college, and a training college founded by Bishop Otter in 1841, with a model school attached to it. Two hundred years ago nearly all the needles made in England came from this town, but the only manufactures now are coopers' and other wooden ware, leather, parchment, and candles. Extensive corn and cattle markets are held. The town has communication with the sea at Chichester harbor, by means of a branch of the Arundel canal, used chiefly for the transportation of coal.—The name Chichester is supposed to be a corruption of Cissanceaster, the camp of Cissa, an Anglo-Saxon chief who repaired it after its partial destruction by the South Saxons under Ælla in 491. It was the capital of the kingdom of Sussex till its conquest by the West

Chichester Cathedral.

Saxons. In December, 1642, the parliamentary forces took it from the royalists, and in 1648 the parliament caused its fortifications to be destroyed. The see of Chichester was originally founded at Selsea in the 7th century, and removed to Chichester toward the end of the 11th. The income of the bishop is £4,200 a year. Chichester gives the title of earl to the Pelham family.

CHICKADEE. See BLACKCAP.

CHICKAHOMINY, a river in S. E. Virginia, near which were fought several important battles during the civil war. It rises in swampy uplands about 20 m. N. W. of Richmond, flows S. E. about 50 m. parallel with and about midway between the James and York rivers, then turns sharply S., and after a winding course of nearly 20 m. falls into the James, about 40 m. S. E. of Richmond, and 10 m. W. of Williamsburg. Toward its mouth it becomes a consid-

erable stream, navigable by small steamers. The military operations of 1862 and 1864 embraced that portion of the river from Bottom's bridge on the south, where it is crossed by the Williamsburg turnpike, to Meadow bridge, 15 m. N. W., where it is crossed by the Fredericksburg railroad. Richmond lies nearly opposite the centre of this line, about 6 m. from the Chickahominy at its nearest approach. Between these points the river flows through a wooded swamp a few hundred yards wide, from which the land slopes gently up about 100 ft. to the level of the surrounding country. In dry weather the stream is here a mere rivulet; but a moderate shower fills the channel, which is a dozen yards wide and 4 ft. deep; a continuous rainfall floods the swamp and overflows the adjacent bottom lands. These are intersected by deep ditches, and even when not overflowed are so soft as to be impassable for cavalry and artillery. The stream was crossed by several rude bridges, and there were here and there fords, accessible only in dry weather. The spring and summer of 1862 were unusually rainy; the channel was always full to the brim, and every shower flooded the swamp and bottoms. Infantry might possibly have picked their way in loose order through the swamp; but horses would have sunk to their girths, and artillery and trains to the axles. An army could cross only by bridges built above the level of the highest floods, and provided with long approaches through the swamps. As a military obstacle the narrow Chickahominy, with its bordering swamps, is more formidable than a broad river which can be crossed by boats, or over which a pontoon bridge may be thrown in a few hours.—Early in the spring of 1862 the Union army of the Potomac, under Gen. McClellan, disembarked near Fortress Monroe, with the design of moving upon Richmond. The natural approach by the James river was commanded by the confederate iron-clad Merrimack, and it was resolved to march up the peninsula formed by the York and James rivers. This peninsula is about 60 m. long, with an average breadth of 12 m. The lower part is covered with swampy forests, and intersected by sluggish creeks. The roads are few and hardly passable by vehicles. After some trials McClellan decided that he could not move his army directly up the peninsula, but must invest and capture Yorktown, near the mouth of the York river, or rather estuary. Yorktown captured, his base of operations would be at West Point, near the junction of the Pamunkey and Mattaponi, which form the York, whence a railroad runs to Richmond, 30 m. W., crossing the Chickahominy about midway. I. WILLIAMSBURG. The siege of Yorktown was the initial step in the peninsular campaign of 1862. Strong works had been here erected, which were placed under the command of Gen. Magruder, who had at the outset barely 15,000 men to defend Yorktown, Gloucester point, on the opposite side of the

York river, and the line across the peninsula, here about 10 m. broad. But the confederate force in northern Virginia numbered about 50,000, of whom 38,000 were soon transferred to Yorktown, so that by April 17 Gen. J. E. Johnston, who now took the command, had 53,000 men, exclusive of cavalry. Against these McClellan had on the 30th 112,000 present for duty, and 6,000 sick and on special duty. The siege of Yorktown began April 5, and by the close of the month the batteries were nearly completed. The 6th of May was fixed upon as the day when fire was to be opened. But two days before Johnston evacuated his works, carrying away everything worth taking; his trains and the mass of his troops were well under way toward Richmond hours before their departure was known by the besiegers. The Union cavalry started in pursuit, and came up with the rear of the enemy, who made a stand near Williamsburg, where some works had been previously erected. Hooker's division soon came up, and on the morning of the 5th commenced a vigorous attack, which was continued throughout the day by a constantly increasing force. Longstreet, who commanded the confederate rear, had gone beyond Williamsburg; but he turned back, and a severe action ensued, which toward evening was decided by a brilliant bayonet charge by Hancock's division. The confederates then abandoned their works; but they had delayed the pursuit long enough for their trains to be beyond reach. The Union loss at the battle of Williamsburg was 1,856 killed and wounded, and 372 missing, more than two thirds of which was in Hooker's division of 9,000 men. The confederate loss is unofficially stated by Gen. Johnston to have been about 1,800; but it was probably considerably larger, for 800 wounded were found next day in the hospitals at Williamsburg, besides many in private houses. "Sickness and the fight at Williamsburg," says Johnston, "reduced our number by 6,000."—McClellan's advance was slow. The right wing kept to the north, striking the Chickahominy at New bridge, directly in front of Richmond; the left, keeping to the south, reached the river at Bottom's bridge, 13 m. below, on May 20. The bulk of the confederates were across the stream, and a detachment at Mechanicsville was easily brushed away by an artillery fire. On the 20th a Union division crossed the river, occupied the high ground, and made two reconnoissances, one reaching beyond the Seven Pines to within four miles of Richmond. The enemy was nowhere found in force, and no traces of defensive works were discovered. The two corps of Keyes and Heintzelman were then sent across the river, taking up their position near the Seven Pines. Johnston, in his retreat, had neglected to tear up the railroad from Richmond to the Pamunkey. He had indeed partially destroyed the bridge by which it crossed the Chickahominy; but by the 26th the road was in operation up

to the river, and the bridge was nearly reconstructed. There was no military reason why the whole Union army should not then have crossed the Chickahominy by Bottom's bridge and the railroad bridge, and moved directly upon Richmond, where the confederate force numbered 54,000. But McClellan, who had considerably more than 100,000, greatly overestimated the numbers opposed to him. He urged that McDowell, who had 32,000 near Fredericksburg, should be sent to him. This had indeed been promised; but the operations of Jackson in the valley of the Shenandoah alarmed the federal authorities, and McDowell was detained to prevent an anticipated attack upon Washington. II. HANOVER COURT HOUSE. Meanwhile McClellan learned on May 25 that there was a considerable body of confederates at Hanover Court House upon his right and partly in his rear. This force consisted of 13,000 raw troops from North Carolina, who were coming down from Gordonsville to Richmond. McClellan supposed that they were moving up from Richmond, and were "in a position either to reënforce Jackson, or to impede McDowell's junction, should he finally move to join us." Fitz John Porter was directed to dislodge this force on the 27th. A fight ensued, the results of which, says McClellan, "were some 200 of the enemy's dead buried by our troops, 730 prisoners sent to the rear, one 12-pound howitzer, one caisson, a large number of small arms, and two railroad trains captured. Our loss amounted to 53 killed, 344 wounded and missing." The confederates, however, reached Richmond, raising Johnston's force to 67,000. III. SEVEN PINES AND FAIR OAKS. On May 28 the Union force was thus posted: The corps of Heintzelman and Keyes, forming the left wing, were on the west side of the Chickahominy, massed checkerwise for a distance of 6 m. along the Williamsburg road. The stronger corps of Sumner, Franklin, and Porter, forming the right wing, were stretched for 18 m. along the east bank of the river. The two wings formed an acute-angled triangle of unequal sides, the apex being at Bottom's bridge. The distance from centre to centre of the wings was barely 5 m., but between them was the Chickahominy, over which there was then no practicable passage except by Bottom's bridge. If the left wing were assailed in force, the right could come to its aid only by a march of about 23 m., which in the condition of the roads at that time could not be made with artillery in less than two days. For a hostile commander with anything like an equal force, there were two courses open: He might throw himself upon the weaker left, with a probability of annihilating it; or he could assail the extremity of the right wing, threatening its weakly guarded line of communications with West Point. Johnston at the end of May tried the first and most obvious plan, and failed by mere accident. Lee, a month later, tried the second plan, and

succeeded, against all military probability. On May 30 Johnston learned the general position of the enemy; he however supposed that only one corps instead of two was across the river, and presumed that he had but 20,000 to deal with, whereas the actual number was something more than 30,000. The attack was to be made by the four divisions of Huger, Smith, Longstreet, and D. H. Hill, numbering about 50,000. During the afternoon and night of the 30th a violent storm swept over the region. The channel of the Chickahominy was already full to the brim, and the stream swollen by the rain would overflow swamp and bottom lands, preventing any aid being sent from the right wing to the left. The attack was to be made simultaneously at daybreak on the 31st. The storm delayed the movements of the troops; but by 8 o'clock Longstreet was in position, waiting for the arrival of Huger, who did not make his appearance. Soon after noon he began the attack. Casey's division of Keyes's corps was three quarters of a mile in advance of the Seven Pines, its pickets being thrown a third of a mile further up to the edge of a wood. The confederates burst through this screen, forced back the pickets to the intrenchments, where a stand was made, and the position was held for three hours against greatly superior numbers; but both flanks being turned, Casey fell back to the Seven Pines. The confederate attack here had been made by the division of Hill. Longstreet now pressed upon the Union centre and left. After an hour and a half of stubborn resistance, the Seven Pines was abandoned, and the troops fell back to a belt of wood, where Heintzelman succeeded in rallying about 1,800 men, who formed a firm front, and poured in a fire so deadly that the assault was checked. The confederates, who had forced the enemy back for two miles, now fell back a little, and passed the night in the camps which they had won; the federals also fell back a mile to an intrenched camp.—Meanwhile another action had been going on at Fair Oaks station, hardly a mile away. The noise of the battle had been heard across the Chickahominy; and McClellan, who was confined to his bed by illness, directed Sumner, who had just constructed two bridges over the Chickahominy, to hold himself in readiness to cross. The river had begun to rise, and the bridges were almost impassable; many of the timbers were already floating. Two of Sumner's divisions, under Sedgwick and Richardson, were advanced to the head of the bridges, ready to cross the moment orders were given. Late in the afternoon tidings came that the battle was going hardily, and Sumner was ordered to move. Sedgwick's division, which got over the shaking bridge, dragged its artillery through the swamp, and, guided by the noise of the firing, moved upon Fair Oaks, where a single brigade of Couch's division of Heintzelman's corps, which had become separated from the main body, was momentarily expecting an attack from Smith's divi-

sion of the confederates. Fair Oaks is somewhat nearer Richmond than the Seven Pines, and here Johnston had posted himself to direct the general conduct of the whole battle. Sumner now took command here, and received the attack, which began at 4 o'clock, and lasted until twilight, when a vigorous charge hurled the confederates back in confusion; and the action here closed at almost the same time with that at the Seven Pines. At this moment Johnston was severely wounded, and just afterward Richardson's division of Sumner's corps came upon the field. The bridge by which it had attempted to cross the Chickahominy had been found impassable, and it was necessary to go to that by which Sedgwick had already crossed. The division was posted, and the two armies bivouacked on the field, so near together that their pickets were within speaking distance. Johnston being disabled, the command of the confederates devolved upon Gen. G. W. Smith, who the next morning (June 1) decided not to attack at the Seven Pines; but the action was renewed near Fair Oaks, the confederate attack falling mainly upon Richardson's division, which had not as yet been engaged. Meanwhile Hooker had come up from the left, and after an hour's hard fighting pushed the enemy from the woods by which they had been sheltered. The confederates along the whole line retreated in confusion to Richmond. The actions of the Seven Pines and Fair Oaks were fought by the confederates with a much smaller force than had been contemplated by Johnston; for Huger's division got lost in the swamps, and never appeared on the field. The entire attacking force was about 38,000. When strengthened by Sumner's two divisions, the entire Union force on that side of the Chickahominy was about the same; but at the beginning of the action they were considerably scattered, while the confederates were massed upon the assailed points; so that on the 31st the confederates had a decided preponderance in action, but the federals had the advantage of slight intrenchments. The Union loss is officially stated at 890 killed, 3,627 wounded, 1,222 missing; 5,739 in all. The confederate loss was probably rather more, but no official statement appears to have been made. Johnston says, "Longstreet reports the loss in his command at about 3,000; Smith reports his loss at 1,233," 4,233 in all; but no mention is made of the loss in Hill's division, which is elsewhere stated to have been 2,500, which would give a total of 6,733. At Richmond these battles were considered a total defeat; and there is little doubt that had McClellan then moved his whole force against Richmond, the city would have fallen into his hands, for as yet it was defended by none of the works which within a few weeks became formidable. Smith held the command only two days, when, being partially disabled by a paralytic stroke, he was replaced by Gen. R. E. Lee.—After the battle of Fair Oaks McClellan for some time

devoted his attention to building new bridges across the Chickahominy. By June 20 eleven of these were measurably complete, of which seven were available for army transport. Earthworks of no great strength were also thrown up in front of the line on the west side of the river, and the bulk of the Union army was gradually transferred to that side. The position was in the midst of a swampy region, and notwithstanding considerable reinforcements, the number and strength of the army very considerably declined. On June 13 Stuart with 1,500 cavalry started upon a daring raid clear around the Union army. He reached the White House, McClellan's main depot on the Pamunkey, destroyed some stores, and recrossed the Chickahominy 14 m. below the Union left, losing only a single man in the expedition. Lee, whose force had by this time become considerably augmented, now resolved upon an important movement. This was to cross the Chickahominy above the Union right, and attack the force on the east bank of the stream. Jackson, who had gathered a considerable army in the valley of the Shenandoah, was to move down and cooperate in this movement; but to veil it, a considerable force was ostentatiously sent from Richmond toward the Shenandoah, giving the impression that a movement from that quarter upon Washington was in contemplation. The ruse only partially succeeded. If the force at Richmond was weakened, the city would be so much the more open to assault. This was now fairly contemplated by McClellan. By June 24 four of his five corps were across the Chickahominy, leaving only Fitz John Porter with 36,000 men on the east bank. On the 25th the Union lines were pushed half a mile forward, and a desultory engagement occurred at a place known as King's school house, each side losing some 600 men. This was preparatory for a general forward movement which McClellan designed on the next day. At 5 o'clock he telegraphed to Washington that the affair was over; he had gained his point, and all was quiet. An hour and a half later he sent a quite different despatch. Jackson's advance was at Hanover Court House; Beauregard was at Richmond; there were 200,000 men opposed to him, and he should probably be attacked the next day; he would do all he could, and if his army was destroyed by overwhelming numbers, he could at least die with it; if the result of the coming engagement should be disaster, he was not responsible for it. This was partly correct. Lee had also fixed upon the 26th for an offensive movement; Jackson's whole force, not merely his advance, was at Hanover Court House. But Beauregard was in Alabama, not in Richmond; and the confederate force, instead of being 200,000 strong, numbered barely half as many. Instead of having to meet an overwhelming force, McClellan had a slight preponderance, having with him on the Chickahominy about 103,000 men present for duty,

while Lee had, including those coming on with Jackson, about 100,000. An allowance of 5,000 on either side will cover all possible errors in this estimate. Lee had reasoned that McClellan intended to lay siege to Richmond by regular approaches. The city was in no condition to sustain a prolonged investment, for it had not provisions for a fortnight, and its sources of supply were precarious and liable to interruption. His object was to raise the siege by attacking McClellan at the point where he was most vulnerable; that is, by threatening his line of supply on the east side of the Chickahominy. For this purpose the divisions of Huger and Magruder, 24,000 strong, Holmes's division of 7,000, which was posted at Fort Darling on the James river, and the reserve artillery and cavalry, 3,000 more, were to be left on the Richmond side; while A. P. Hill, Longstreet, and D. H. Hill, with 34,000, besides 2,000 cavalry under Stuart, were to cross the Chickahominy and unite with Jackson's command, 30,000 strong, and fall upon the enemy on that side. IV. MECHANICSVILLE. The divisions from Richmond began moving during the night of Thursday, June 25, and reached their assigned positions at 8 o'clock the following morning. They waited till the afternoon for Jackson's approach. He had been delayed, and at last A. P. Hill crossed the stream beyond the extreme Union right, and moved down the bank until he came upon two brigades of McCall's Pennsylvania reserves strongly posted behind Beaver Dam creek, a small stream falling into the Chickahominy. The creek was five or six yards wide, with steep banks, the water being waist deep. The roads approaching it were commanded by artillery, and the whole line was defended by rifle pits and felled trees. The confederates made several determined attacks, which were repelled; and at 9 o'clock they fell back, having lost 1,500 men. The federals, fighting under cover, lost barely 300. In this action, sometimes called the battle of Mechanicsville, sometimes that of Beaver Dam creek, the Union force engaged consisted of the brigades of Reynolds and Seymour, 6,000 strong; that of the confederates of five brigades, numbering 12,000.—From the moment that McClellan learned of the approach of the enemy, he gave up all thought of holding his position on the east bank of the Chickahominy, and began to execute the plan which he had already conceived of changing his base from the York to the James; a wise operation, which had been perfectly feasible since the destruction of the Merrimack on May 11. The quartermaster at West Point was ordered to forward supplies to the front till the last moment, and to send the remainder to the James, burning everything which could not be got off. His change of base required that the whole army should be united on the west side of the Chickahominy. McClellan proposed to hold the enemy in check for a few hours on the east side until all his trains could be got over. The

position at Beaver Dam creek was considerably in advance of the main line, and though unassailable in front could be easily turned. V. COLD HARBOR. During the night of the 26th the troops were quietly withdrawn. Porter's line was posted 5 m. below. The 30 heavy guns which had been placed in batteries between these points, together with nearly all the trains, were safely conveyed over, and the New bridge partially destroyed. There was indeed no necessity for fighting the battle which ensued, for the whole Union army might easily have got over hours before the enemy came in sight on the 27th. The Union position was well chosen. A small stream falling into the Chickahominy was in front. The banks were usually fringed with a belt of swamp; but here and there they were steep. The land rises into a flat table land, with patches of forest and cultivated fields. Two places are named on the maps, New Cold Harbor, near the Chickahominy, and Cold Harbor, a mile northward, each consisting of three or four dilapidated houses. Cold Harbor formed the centre of Porter's semicircular line, which covered the bridges across the river. Some rifle pits had been dug and a few trees felled along the sides of the slope, which was crowned with artillery, so that the guns could play over the heads of the infantry upon an advancing enemy. The confederates were astir at dawn, but it was two hours before they began to move. A. P. Hill and Longstreet kept to the right, along the bank of the Chickahominy. D. H. Hill bore to the left in order to unite with Jackson, who had encamped near by. About noon the right column came to Gaines's mill, where a slight encounter took place, from which has been given one of the names by which the whole battle is designated. At 2 o'clock A. P. Hill came in sight of the main Union force drawn up on the hillside beyond the creek. The plain in front, a quarter of a mile wide, was swept by artillery and partly commanded by heavy guns on the opposite side of the Chickahominy. The confederates charged across the plain, floundered through the morass, and pressed up the slope in the face of a fierce fire of artillery and musketry. Some regiments even pierced the Union lines. The battle here raged for two hours, but the assailants were at length driven back in apparent rout. Longstreet's division had been drawn up in the rear of Hill, sheltered by a low ridge. Lee directed him to make a feigned attack upon the Union left, in order to relieve Hill. He found that the force there was too strong to be disturbed by a feint, and that he must make a real attack. Jackson had now come up on the Union right. The direction of the firing showed that on the left A. P. Hill and Longstreet were falling back. Lee ordered a general assault. Porter, seeing the great force advancing upon him, had two hours before asked for reinforcements from the other side of the Chickahominy. Slocum's division had been all day kept in readi-

ness for that purpose. It had begun to cross at daybreak, but was recalled when half over. It was now ordered to move, and came upon the field at half past 4. Porter's line was so severely pressed everywhere that he was compelled to send Slocum's division, regiment by regiment, to the most vital points. Still for more than an hour Jackson gained no ground. Lawton's Georgia brigade, 4,000 strong, which had been held in reserve, was now ordered up. It was half past 6, an hour before sunset. The whole force, except a single confederate brigade held in reserve, was now in action. Making allowance for losses on both sides, the confederates on the field numbered 56,000, the federals 33,000. The Union force was thus pressed along its whole line by almost double its numbers. It gave way almost simultaneously on the right, centre, and left. It was not a rout, but fast threatening to become one. The core of every division remained solid, but fragments were flying off on every side, and all were pressing toward the bridges across the Chickahominy. At this moment the brigades of French and Meagher came over the river, dashed through the stragglers, and up the bluff. The regiments in retreat rallied and faced the pursuers, who fired a few ineffectual volleys, and withdrew as night set in. An hour earlier these two brigades would have secured a victory; as it was, they just prevented a disastrous rout. This action of June 27 has been called the battle of Gaines's Mill, but is more properly that of Cold Harbor; Lee calls it the battle of the Chickahominy. The confederate loss in killed and wounded was 9,500; the Union loss 4,000, besides about 2,000 prisoners, and 22 guns. During the whole of this action McClellan had remained on the west side of the Chickahominy, where the confederates kept up a show of force far greater than they possessed. For this the formation of the country furnished special facilities. There was a continuous series of swamps, gullies, and ridges, which shut out from view all that was passing at the distance of a few hundred yards. A force would show itself at one point, vanish, and reappear at another; no one could tell whether it was a regiment or a division. An artillery fire might be a feint or the prelude to an attack in force. These movements deceived not only McClellan but Sumner and Franklin, both of whom thought they were confronted by superior numbers. But the only affair which rose even to the dimensions of a skirmish occurred near sunset, when two confederate regiments attacked a strong picket line at Peach Orchard, and out of 650 men lost 200.—Lee had won a formal victory, in which he suffered double the loss which he had inflicted. But he had placed himself in a perilous position. Two thirds of his force, now not more than 54,000, was east of the Chickahominy, the remaining 35,000 on the west, of whom 7,000 were across the James. Between them lay McClellan with

fully 96,000. A third of this would easily have guarded the river; the remainder could have marched into Richmond in five hours. The fall of Richmond would have involved the dissolution of the army across the Chickahominy, for it had marched out with only three days' supplies; and out of Richmond the confederates had not within 100 m. food to supply the soldiers for a week. The confederate army after the battle of Cold Harbor was in just the position in which an enemy would wish it to be. McClellan, instead of assaulting or besieging Richmond, resolved to move to the James river. VI. SAVAGE'S STATION. The problem, sometimes called the "change of base," but in reality a retreat, was a very simple one. It was to march 10 or 15 m. with no enemy in front, but with one supposed to be superior upon one flank and possibly in the rear. White Oak creek falls into the Chickahominy three or four miles south of the left of the Union position at the Seven Pines. It is bordered by White Oak swamp, which toward Richmond is several miles wide, and slopes up into a wooded tract extending to the James river. Three main roads, the Charles City, Darbytown, and Newmarket, starting from near Richmond, diverge southeastward toward the Chickahominy, skirting the swamp on its southern side. The region is intersected by obscure cross roads, upon which there is here and there a clearing. In this region took place the engagements of June 30. The line of the retreat lay through White Oak swamp. The trains, which if drawn up in a single line would have stretched a distance of 40 m., and were accompanied by a herd of 2,500 cattle, were got safely over the creek by noon of the 28th, and, preceded by Keyes's corps, moved toward Malvern hill on the James, which they reached without molestation on the morning of the 30th. The corps of Franklin and Porter followed on the morning of the 29th, leaving those of Sumner and Heintzelman to protect the rear. The works at Fair Oaks and Seven Pines were abandoned, and the two corps fell back to Savage's station, on the railroad, where were the hospitals and depots of the army, which they were directed to hold till nightfall. Heintzelman moved away before the time, leaving orders for the destruction of such stores as could not be carried off. The provisions were piled up and burned. The ammunition and shells were heaped upon a train, which with a full head of steam was sent down the railroad toward the river; as it started the train was set afire, and before it reached the bridge the shells began to explode. The rails across the bridge had been removed; but so great was the momentum that the engine and one car leaped across the chasm and landed on the opposite side. At the same instant the whole mass of powder exploded, and the other cars plunged into the mud of the river. Magruder in the mean time moved cautiously down the railroad, somewhat harassing the retreat, and at half past 5 made an attack at

Savage's station, then occupied by Sumner. Darkness put a close to the action; and during the night Sumner moved off, leaving behind 2,500 sick and wounded in the hospital. In the engagement at Savage's station the Union loss was about 600, that of the confederates 400.

VII. FRAZIER'S FARM. Early on the morning of the 30th Magruder and Huger were directed by Lee to move from Richmond down the Charles City and Newmarket roads to take part in the flank attack which was meditated, in which they were to be joined by Holmes and Wise from Fort Darling. In this attack the entire effective confederate force, numbering more than 85,000, was to take part. Early on the morning of the 29th A. P. Hill and Longstreet crossed the Chickahominy by the New bridge, which had been only partially destroyed on the 26th, passed through the deserted Union lines almost to Richmond, turned eastward, and heading the White Oak swamp moved down the Darbytown road, and at nightfall, after a march of 20 m., encamped not far from the centre of McClellan's retreating column. The day had been intensely hot, and many of the men dropped from the ranks. The Union line was 8 m. long, the head having almost reached Malvern hill, the rear being at the crossing of White Oak creek. The bridges over the Chickahominy in front of Jackson were down, and he was unable to repair them until the morning of the 30th, when he crossed, and by noon came to White Oak creek, the bridge over which was destroyed, and all the approaches commanded by artillery. He was detained here all the afternoon, unable to take part in the battle which was going on two miles distant. Early in the morning Holmes and Wise had come in sight of the head of McClellan's column, upon which they opened a distant fire; but a few rounds of artillery and a few shells from the gunboats scattered their force, which took no further part in the operations which ensued. Longstreet and A. P. Hill resumed their march down the Darbytown road, and at noon came in sight of a part of the Union line drawn up at Frazier's farm, near a point where a road leading from the James crosses those from Richmond. Huger was supposed to be moving by the Charles City road upon the same point; but he mistook the way, and did not make his appearance that day, and on the next he was virtually removed from the command of his division. The Union line was so long that it was unoccupied in places. McCall's division was at Frazier's farm; Kearny's on his left, on his right that of Hooker, and beyond him Sumner's corps. Keyes's and Porter's corps had nearly reached Malvern hill; Franklin's corps was in the rear, at White Oak creek. At 4 o'clock the attack was begun upon McCall by Kemper's brigade of Longstreet's division, which had not as yet been engaged, having been kept in reserve at Cold Harbor. It was driven back, losing in a few minutes 250 killed and wounded and 200 prisoners, a quarter of

its whole number. Other divisions were sent in, and McCall was forced back for a space; then the enemy were checked by Hooker, and in return driven back. The whole action now took the form of a desultory fight, each brigade on both sides acting almost independently; batteries were taken and retaken, and ground lost and won by each army; but when night closed in the advantage seemed somewhat on the Union side. McCall's early repulse in the centre had been retrieved, and Hooker and Kearny had gained something on the right and left. Of all the reports on both sides, that of A. P. Hill is the most accurate: "On our extreme right matters seemed to be going badly. Two brigades of Longstreet's division had been roughly handled, and had fallen back. Archer was brought up and sent in, and affairs were soon restored in that quarter. At about dark the enemy were pressing us hard along our whole line, and my last reserve was directed to advance slowly. Heavy reinforcements to the enemy were brought up at this time, and it seemed that a tremendous effort was being made to turn the fortunes of the day. The volume of fire that approaching rolled along the line was terrific. Seeing some troops of Wilcox's brigade who had rallied, they were rapidly reformed, and, being directed to cheer long and loudly, moved again to the fight. This seemed to end the contest, for in less than five minutes all firing ceased, and the enemy retired." The attempt to break the Union line had failed. The action was hardly over when the federal retreat was resumed. The rear of the wagon train and artillery had reached Malvern hill at 4 o'clock in the afternoon; and before daylight the last division had come up and taken the position assigned to it. The battle of Frazier's farm, or Charles City cross roads, as it is sometimes called, was fought on the confederate side wholly by the divisions of A. P. Hill and Longstreet. They had crossed the Chickahominy 24,000 strong, and had in the mean time lost 8,200 in killed and wounded. They were so exhausted by four days' continuous marching and fighting as to be unable to take any part in the battle of the next day. The Union loss on this day was about 300 killed and 1,500 wounded; that of the confederates 325 killed and 1,700 wounded.

VIII. MALVERN HILL. On the morning of Tuesday, July 1, the Union army was posted in a strong position at Malvern hill, an elevated plateau a mile and a half long, and half as broad. The flanks were well covered by woods; in front were gullies rendering the approach difficult except by the roads which crossed them. On the crest of the hill seven heavy siege guns were placed in position, and the artillery was so posted that a fire of 60 guns could be concentrated upon any point which might be assailed. The position was one which could be held against a double force. McClellan had about 90,000 men; Lee, counting every man except the divisions of A. P. Hill and Longstreet, not more than 60,000,

with only a portion of which he undertook to storm the Union position. It is clear that he all along vastly underrated the strength of the enemy. When he crossed the Chickahominy on the 26th, he supposed that the greater part of McClellan's army was on the east side; but at Cold Harbor he himself had clearly a great preponderance of numbers, and he might fairly assume that the enemy was weak on the other side, otherwise he would have brought more men upon that field. At Frazier's farm the two divisions of Hill and Longstreet evidently were as strong as the force opposed to them; and if they were too much exhausted to be brought into action, so too would be those with whom they had fought. The dispositions made by Lee for the attack clearly evince that he did not suppose himself to be confronted at Malvern hill by an effective force of more than 50,000 men. At 9 o'clock in the morning Jackson received orders to attack. Including D. H. Hill's division, which now formed a part of his command, he had, after deducting all losses, about 35,000 men. Hill, being on the confederate right, was opposite the Union left, where Hooker was posted. He suffered so severely from the artillery fire that he halted to reconnoitre, and found the enemy, as he reports, "strongly posted on a commanding hill, all the approaches to which could be swept by his artillery and guarded by swarms of infantry, securely sheltered by fences, ditches, and ravines. Tier after tier of batteries were grimly visible on the plateau, rising in the form of an amphitheatre. We could only reach the first line of batteries by traversing an open space of from 300 to 400 yards, exposed to a murderous fire of grape and canister from the artillery, and musketry from the infantry. If that was carried, another and still more difficult remained in the rear. An examination convinced me that an attack would be hazardous." The assault here was suspended; but Lee still persisted. He sent to each of his commanders a brief message, each word of which cost him a hundred men: "Batteries have been established to act upon the enemy's lines. If they are broken, as is probable, Armistead, who can witness the effect of the fire, has been ordered to charge with a yell. Do the same." This second attack was to be made by Magruder with 20,000 men, comprising his own division and that of Huger, who had been displaced. Magruder, after a long and weary march, came up, and found that Armistead, of Huger's division, had driven some skirmishers. The Union line was thought to be broken. "It is reported," Lee wrote to Magruder, "that the enemy is getting off; press forward your whole line, and follow up Armistead's success." Hill pressed forward with the others, and in an hour and a half his division, now reduced to 8,000, lost 336 killed and 1,373 wounded. Magruder's attack failed to make any real impression; his men were mown down as they advanced by a terrific fire of artillery and musketry, which cost him some 500 killed and

2,000 wounded. The battle closed when darkness set in. On the confederate side it had been borne almost wholly by the divisions of D. H. Hill and Magruder, together not more than 28,000 strong. Jackson's own division was not fairly engaged, but being within distant range of the Union artillery it lost 41 killed and 363 wounded. Longstreet, A. P. Hill, and Holmes had no part in the battle. The Union loss at Malvern hill was about 375 killed and 1,800 wounded; the confederate loss, 900 killed and 3,500 wounded.—The series of engagements from June 26 to July 1 has been styled the "seven days' battles," although there were really but six days. In all, including skirmishes, the Union loss appears to have been 1,582 killed and 7,709 wounded; that of the confederates nearly twice as great, being 3,150 killed and 15,255 wounded. The former lost also 5,958 in missing, of whom 2,000 were the prisoners at Cold Harbor, and 2,500 in the hospitals at Savage's station; the confederate loss in prisoners was about 1,000. So that the entire Union loss was 15,249; confederate, 19,405. Had McClellan followed up the victory at Malvern hill within the next day or two, the confederate army must have been annihilated. But instead of doing this, during the night following he abandoned his strong position, and retreated to an unhealthy one at Harrison's landing, where he intrenched himself, and pleaded for reinforcements. At first he asked for 50,000, then for 100,000. Three weeks later he said if he could have 30,000 he might attack Richmond with a good chance of success, though he would then have an effective force of only 120,000, while he estimated that of the enemy at 200,000. So matters rested until the middle of August, when the Union army was withdrawn from the region of the Chickahominy and the James, and ordered to the Potomac. After the battle of Malvern hill the confederates remained for a week near the spot, and then returned to Richmond. Lee had accomplished his main purpose of raising the siege of the confederate capital. IX. SECOND COLD HARBOR. In the spring of 1864 the current of the war again rolled toward the Chickahominy. The command of the Union army was given to Grant, who encountered Lee in the bloody but indecisive battles of the Wilderness, May 5, 6; Spottsylvania, May 11; and the North Anna, May 25. All this time the two armies had been verging toward the region where they had contended two years before. On June 2 Lee had taken up his position near Cold Harbor, while Grant was marching toward him from the same direction in which Jackson had marched upon Porter. The confederate position was strongly intrenched. Lee could retreat no further, for behind him was the Chickahominy, now unbridged, and he could not cross it without winning a decisive battle. Grant, whose force was now about 150,000, while Lee had barely 50,000, resolved to attack the enemy in his intrenchments; if

he could be forced from these, he must retreat up the bank of the Chickahominy, pressed by threefold numbers. The plan of attack was simple. Hancock's corps was on the left, then Wright's, then Smith's, massed opposite the confederate right; Warren's corps came next, stretched in a long thin line, which was continued by Burnside's, whose right was flung back. In the gray rainy dawn of the 3d these corps rushed upon the confederate lines. Barlow's division of Hancock's corps, formed into two lines, struck a sunken road in front of the confederate intrenchments, where they met a solid mass of fire and lead, which in a quarter of an hour drove them back, with the loss of a third of their numbers. Gibbon's division, which was next on the right, dashed up to the works, breasting a torrent of musketry, in the face of which they mounted the parapets; but they could go no further, and were soon repelled. Wright and Smith assaulted with like ill fortune, though they maintained the fight for an hour. Warren was only to hold in check the enemy directly in his front; while Burnside, swinging round, was to fall upon the confederate left. He drove in the outposts, but before he could execute the order to attack in force, it was countermanded; for Meade, who commanded in the field, thought the failure of the assault on the left showed that the confederate works could not be carried. The skirmish line was withdrawn, and the corps set about intrenching itself in its position, upon which the confederates made a feeble sortie, which was easily repulsed. With this closed the second battle of Cold Harbor, in which Grant had wholly failed. His loss was severe, probably not less than 7,000 in killed and wounded; that of the confederates being less than half as many.—For ten days longer the two armies lay facing each other on the east side of the Chickahominy, Grant edging to the southward, still hoping to be able to turn the confederate right; Lee at the same time extending his intrenched line in the same direction. A continual series of skirmishing and picket firing was kept up, only interrupted on June 7 by a truce in order to bury the dead. Grant, while making preparations to move his army to the south side of the James river, still hoped that Lee would make some movement which would furnish opportunity for another attack on the Chickahominy. But Lee showed no disposition to move from his intrenchments, which the experience at Cold Harbor had shown to be unassailable. At length on the 12th Grant broke up his position. The bulk of the army marched down the Chickahominy to the James, which was crossed just below the point where McClellan had remained after the battle of Malvern hill. A portion of the army, however, crossed the Chickahominy below the White Oak swamp. Lee, who could only see this part of the movement, supposed that Grant proposed to march up the north bank of the James, and assail Richmond from that side.

He therefore abandoned his position on the east bank of the Chickahominy, crossed the stream, and fell back within his strong lines in front of Richmond.

CHICKAMAUGA, Battle of, fought upon Chickamauga creek, an affluent of the Tennessee river, 12 m. S. W. of Chattanooga, in S. Tennessee, Sept. 19, 20, 1863, between the Union army of the Cumberland, under Gen. Rosecrans, and the confederates under Gen. Bragg. During the summer Rosecrans had moved into southern Tennessee, and on Sept. 9 had taken possession of Chattanooga, from which Bragg had retired on his approach. Rosecrans, supposing that the enemy were in full retreat in Georgia, moved after them; but Bragg, having received large reinforcements, and knowing that Longstreet's division from Virginia was on its way to him, resolved to give battle, with the special purpose of recovering Chattanooga. Both armies were considerably scattered in that mountainous region; but on the 18th the forces on both sides were concentrated on the Chickamauga creek. The main battle was opened on the morning of the 19th, the immediate object of the confederates being to gain possession of the road leading to Chattanooga. The fighting was hot all day, but at its close neither side had gained any decided advantage. During the night Longstreet arrived with a portion of his division, and was appointed to the immediate command on the confederate left, that on the right being given to Polk. Thomas, who commanded on the Union left, was first attacked by Polk, who was repulsed. But in the mean time Longstreet had been more successful, and was hardly pressing the Union right and centre, where Rosecrans commanded in person. Owing to an erroneous order from Rosecrans to Gen. T. J. Wood, a movement was made which left a wide gap in the Union centre. The confederates poured through this, and routed part of Crittenden's and all of McCook's army corps, driving them from the field in utter confusion. Rosecrans, who had fled to Chattanooga, telegraphed to Washington that his whole army was beaten. But on the left Thomas still held his own. He had taken up a strong line, and awaited the coming attack from the whole confederate force. Longstreet, who actually directed the battle, now pressed the whole confederate strength against Thomas, who was outnumbered more than two to one. Assault after assault was made, but each was repulsed; and at half past 5 the attack was abandoned. Thomas then fell back to Rossville; and during the night of the 21st the whole of his command returned to Chattanooga. This battle was a formal victory for the confederates, who retained the battle field, and captured 40 or 50 guns and some thousands of prisoners, mainly wounded. They however gained no real advantage, for Rosecrans still retained Chattanooga, the prize for which the action was fought. The confederate force actually engaged was about

50,000; the Union force was about 55,000, but of this more than 10,000 were isolated early in the day, and took no further part in the battle. In this estimate the cavalry on either side are not included, as they had no scope for action. The Union loss is officially stated at 1,644 killed, 9,262 wounded, and 4,945 prisoners; 15,851 in all. The confederate reports are wanting for about one third of the force, including Longstreet's own brigades, which were most severely engaged. In the two thirds reported, the loss was 1,394 killed, 8,974 wounded, and 882 missing, 11,250 in all; the entire loss being not far from 18,000. A month after this battle Rosecrans was relieved from the command of the army of the Cumberland, which was incorporated with the armies of the Ohio and the Tennessee, and placed under command of Gen. Grant, who on Nov. 23-25, 1863, defeated Gen. Bragg in front of Chattanooga. (See CHATTANOOGA.)

CHICKAREE, a name given, from its loud chattering note, to the red, Hudson bay, or pine squirrel (*Sciurus Hudsonius*, Pall.). The body is stout, 7 to 8 inches long, and the tail

Chickaree (*Sciurus Hudsonius*).

rather less, narrow and flat; ears moderate, broad, tufted at the tip. The color above and on the sides is a mixed black and grayish rusty, with a broad wash of bright ferruginous down the back and upper surface of the tail; dull white below; tail rusty at the margin, within which is a narrow black band; there is often a black line on the flanks separating the colors of the sides and belly; soles hairy or naked according to the season. It is found from high northern latitudes to the Mississippi, and throughout the northern and middle Atlantic states in elevated regions. It is active, graceful, fearless of man, cleanly, and industrious in laying up a winter supply of food; it sometimes makes its nest in outbuildings; it is very lively all winter, eating its store of nuts, and the seeds of pines and firs; in cold climates it burrows in the ground at the foot of some large coniferous tree. Its flesh is tender and well-flavored; it is less gentle and easily tamed than the gray squirrel. It much resembles the common squirrel of Europe (*S. vulgaris*, Linn.).

CHICKASAW. I. A N. E. county of Mississippi; area, about 990 sq. m.; pop. in 1870, 19,899, of whom 10,069 were colored. It was ceded to the state by the Chickasaw Indians. The surface is level, and the soil fertile. The Oktibbeha, Looshacona, and Yallahusha are the principal streams. The Mobile and Ohio railroad crosses the N. E. corner. The chief productions in 1870 were 6,669 bushels of wheat, 478,406 of Indian corn, 16,992 of oats, 36,314 of sweet potatoes, and 8,892 bales of cotton. There were 2,366 horses, 2,193 mules and asses, 4,067 milch cows, 6,911 other cattle, 4,980 sheep, and 25,813 swine. Capital, Houston.

II. A N. E. county of Iowa, intersected by the Wapsipinicon river and its tributaries, and also drained by Crane creek and the Little Cedar river; area, 576 sq. m.; pop. in 1870, 10,180. Prairies and forests occupy most of the surface. The Cedar Falls and Minnesota railroad touches the S. W. corner, and the McGregor and Missouri River railroad passes through the county. The chief productions in 1870 were 417,849 bushels of wheat, 386,723 of Indian corn, 334,521 of oats, 22,762 of barley, 62,462 of potatoes, 34,651 tons of hay, 422,338 lbs. of butter, and 13,426 of wool. There were 3,558 horses, 4,736 milch cows, 7,919 other cattle, 4,830 sheep, and 6,206 swine. Capital, New Hampton.

CHICKASAW BAYOU, Battle of, fought near Vicksburg, Miss., Dec. 29, 1862. Gen. Sherman, who was besieging Vicksburg, finding the city unassailable in front, endeavored to attack it in the rear. He sent a strong force 10 m. up the Yazoo river, which was to land and march down from the north. In the way of this march was the Chickasaw bayou, setting out from the Yazoo, bordered by a broad miry swamp, almost impassable, and guarded by batteries and rifle pits. These were held in such force that all attempts to cross the bayou failed, and the enterprise was abandoned, having cost 192 killed, 982 wounded, and 756 missing. The confederate loss was insignificant.

CHICKASAWS, a nation of American Indians, residing when first known to the whites about 160 m. E. of the Mississippi, between lat. 34° and 35° N. According to their own tradition, they came from west of the Mississippi with the Creeks and Choctaws. When about to start eastward, they were provided with a large dog as a guard and a pole as a guide. As they marched they planted the pole in the ground every night, and in the morning looked at it and went in the way it leaned. They crossed the Mississippi, in which their guardian dog was drowned, and arrived on the Alabama, where their pole, after being unsettled for several days, at length pointed southwest. They proceeded in that direction to what is known as the Chickasaw old fields, where the pole remained perfectly upright. In 1540 De Soto reached Chicaça, one of their towns in what is now the northern part of the state of Mississippi, and wintered there. But

when in the spring he wished to force them to supply men to carry his baggage, they fired their town and attacked him, causing great loss. When the French settled Louisiana the Chickasaws had already been visited by traders from the English colonies, and thus came into the struggle of the rival nations. They had at one time, it is said, 10,000 warriors, but in 1720 numbered only 450, in four large contiguous settlements, Yaneka and Chookka Pharaah (Long House) being the most important. They were divided into five clans or families, Minko, Showa, Coishto, Oushpehne, Minne, and Huscona, and recognized a king or *mico* as head of the nation. They began hostilities against the French in 1722, killing a sergeant and his wife near the Yazoo post. In 1732 they cut to pieces a war party of the Iroquois who invaded their territory, but in 1746 were cooperating with that confederacy against the French. By advice of English traders they urged the Natchez to cut off the French, and after the overthrow of that nation gave a refuge to the remnant who escaped from the vengeance of the French. They then took up arms openly, cut off all trade on the Mississippi river, and joined the desperate Natchez in their raids. They killed the chief of the Tonicas by treachery, and besieged Denys at Fort Nachitoches, but were repulsed there with loss. This led to a war, and in 1736 the French attempted to crush them by a simultaneous attack from the south under Bienville and from Illinois under D'Artaguette. The former retired; the latter took several of the Chickasaw towns, but was defeated and taken at Amalahta with Vincennes, Père Senat, and others, all of whom were put to death. In 1739 a very formidable expedition ascended the Mississippi under Bienville and De Noailles, but they halted near Chickasaw Bluff, and after some skirmishes made a hollow peace with the Chickasaw envoys in August, 1740, though hostilities were kept up in a desultory way for the next ten years. The Chickasaws entered into friendly relations with Gen. Oglethorpe, and seem to have maintained them. In 1765 their head men and warriors, with those of the Choctaws, met Gov. George Johnstone of West Florida in a general congress at Mobile, and established a regular tariff of trade; but troubles were soon caused by grasping traders who had settled among the Chickasaws. After the revolution the United States made a treaty at Hopewell in 1786 with Pío Mico and other chiefs, fixing their territory at the Ohio on the north, and running down into what is now Mississippi. They were then estimated at from 800 to 1,200 warriors, but as their territory was remote from settlements there had been no encroachments or collisions. When the Creeks drove them to war in 1793, they joined the whites in operations against the Creeks, remaining constantly friendly to the settlers, although surrounded by hostile tribes. In 1805, 1816, and 1818 Chenubbe Mico and

other chiefs ceded all their lands north of Mississippi for certain specified annual payments; the Colberts, influential men of the tribe, aware of the value of the lands, securing better terms than usual. The scarcity of game and the narrowing of their hunting grounds had led some of the tribe to emigrate to the Arkansas about the beginning of the present century. In 1822 those remaining in Mississippi comprised 3,625 souls in eight towns, advancing in civilization, owning slaves, and selling cattle and hogs to the whites. When the United States adopted the plan of removing all Indians west of the Mississippi, the Chickasaws, by the treaties of Pontotoc Creek, Oct. 20, 1832, and Washington, May 24, 1834, ceded to the United States all their remaining lands in Mississippi, amounting to 6,442,400 acres, for which they received \$3,646,000. They had determined to settle on lands already assigned to the Choctaws, who speak the same language. By a convention, Jan. 17, 1837, they paid the Choctaws \$530,000 for a district on the Red west and south of the Washita, to be held by them as a tribe and in common, and inalienable except with the consent of the Choctaws. They were also to abandon their government by a king and form part of the Choctaw nation, governed under its constitution, with equal representation. During the emigration smallpox broke out, carrying off 500 or 600 of the tribe. They did not all settle on their new tract, but scattered through the Choctaw country as they found lands to suit them, some wealthy men like Col. Colbert taking up large tracts for cotton, and employing numerous slaves in its culture. As a body they did not advance as rapidly as the Choctaws, their large annuity (\$60,000 among about 4,200) encouraging idleness. They were harassed by some neighboring tribes, and had no schools till an academy was opened in 1851. Their political condition also caused discontent, as, instead of equal representation as they expected, they were allowed only in proportion to population, and were a powerless minority. They appealed to the President of the United States, and on paying \$150,000 to the Choctaws obtained by treaty of June 22, 1855, a political separation from them and a complete title to the Chickasaw district. Here they organized a new government of their own, and have since been recognized as a distinct tribe. Their progress after this was rapid, but the civil war was a severe blow to them. Like the Choctaws, the Chickasaws first joined the south, led by their agents; and though there were no military operations in their district or contest in the tribe, they lost nearly one fourth of their population, much stock, and of course their slaves. By the treaty of Fort Smith, September, 1865, the Chickasaws with other tribes, held to have forfeited all their rights by rebellion, were restored on certain conditions and new treaties made. By another treaty, April 28, 1866, the

United States government reaffirmed all the old treaty stipulations, and the Chickasaws gave up nearly 7,000,000 acres of land at 4½ cents an acre, the money to go to their late slaves unless within two years they accepted them as members of the tribe. The Chickasaws were very loath to lose the money or adopt the negroes, but finally accepted the latter alternative, Jan. 10, 1873. Since the war they have recovered greatly; they have 14 schools and about 500 pupils. Their government consists of a governor, senate, and house of representatives. The lands are still held in common, though by act of Sept. 28, 1872, steps were taken to divide it among the members of the tribe. Their stock has always been individual property. In 1871 they owned 4,500 horses, 15,000 sheep, and 25,000 swine; they had 14,500 acres under cultivation, raising 300 bales of cotton and 380,000 bushels of corn. They receive a perpetual annuity of \$3,000, and have in the hands of government nearly \$1,200,000 in bonds, of which they receive the annual interest.

CHICKEN POX (*varicella*), an exanthematous disease, characterized by the eruption of small vesicles appearing in successive crops. It is confined almost exclusively to children. The eruption is preceded by more or less fever for a day or two; it appears first on the back, neck, and breast, whence it spreads to the face, limbs, and body. The eruption is very early, if not from the beginning, vesicular, resembling drops of water about the size of split peas, the contained fluid being transparent or straw-colored; they sometimes run together, and assume a conical or globular form, which has given rise to the described varieties; they are usually surrounded by slight redness, and accompanied by considerable itching, which causes them to be very soon broken. About the fifth day they begin to dry up in scales, which fall off in a few days, leaving a discoloration and sometimes a slight permanent pitting of the skin. Sometimes the contents of the vesicles become pustular, accompanied by higher and more lasting fever; English writers call such cases swine pox. The Latin name *varicella* is a diminutive of *variola* (smallpox), from the opinion which formerly prevailed that the two diseases were nearly allied, variola, varioloid, and varicella being all considered varieties of smallpox; but chicken pox is now understood to be a distinct affection. It may be distinguished from smallpox by its mildness, vesicular character, and the successive appearance of its eruption; though some severe cases are with difficulty distinguished from mild varioloid. It occurs in persons who have been vaccinated and who have had smallpox, and in those who have not experienced vaccination, varioloid, or variola; though often prevalent at the same time with variola, it has not been known to communicate the varioloid or the smallpox; it is not certain that it can be transmitted by inoculation, and it is generally considered

very slightly, if at all, contagious. It is a disease unattended with danger, unless from accidental complications, and requires no treatment other than attention to diet, mild laxatives, and cooling drinks.

CHICKEN SNAKE, a name given in the northern states to the *coluber eximius* (De Kay), *ophibolus eximius* and *O. clericus* (Bd. and Gd.). The head is short and the snout rounded; the nostrils are lateral, the eyes large, with a dusky pupil and gray iris; the neck is contracted, the body long but robust, covered with smooth, small hexagonal scales above, and with broad plates below; the tail is short, thick, soon becoming cylindrical, and ending in a horny tip. The color, as described by Holbrook, is milky white above, sometimes tinged with red; along the vertebral line is a series of dusky oval spots, bordered with black, sometimes giving the appearance of transverse white and black bands (as described in Storer's report on the Massachusetts reptiles); alternating with these bands on the sides is another series of smaller rounded and blacker spots, and sometimes a third smaller series lower down; the upper lip is

Chicken Snake (*Ophibolus eximius*).

milky white; the abdomen is silver white, sometimes yellowish; each plate marked with one or two black spots, quadrilateral, near the centre if single and near the margin if double, giving a tessellated appearance, whence the specific name *calligaster* given by Say to the western variety; in a specimen 3 ft. long, the head was 11 lines, body 30 in., and the tail about 5 in.; the abdominal plates 198 to 208, and the subcaudal scales 47; it grows to the length of 5 ft. It is perfectly harmless; from its frequenting houses and dairies, it has been called "house snake" and "milk snake." It feeds on frogs, toads, mice, insects, and small birds. It does not appear to be found below lat. 37° N.; westward it extends to the Mississippi; it prefers shady and rocky places; in the southern states it is replaced by *scotophis guttatus*.—The chicken snake of the south is *scotophis quadrivittatus* (Bd. and Gd.); the body is very long; above, a greenish clay color, with four longitudinal brown bands; yellowish beneath; scales on the back ridged, on the sides smooth; the head is quite distinct; the tail is one fifth of the whole length; in a specimen 4½ ft. long, the head was 1¼ in., body 3½ ft., and tail 10 in.; 233 abdom-

inal plates and 90 subcaudal scales; it is said to attain a length of 7 ft. It is found from North Carolina southward, and to the Mississippi; it destroys rats, young chickens, and small animals, but its bite is harmless to man; it is sometimes found on trees.

CHICKERING, Jonas, an American pianoforte manufacturer, born at Mason Village, N. H., April 5, 1798, died in Boston, Dec. 8, 1853. He was put to the trade of a cabinetmaker, but early evinced great fondness for music, and successfully readjusted and tuned an old and disused piano which he found in the town. In 1818 he became a workman in Boston in a pianoforte manufactory, and five years later began the business for himself. He extended his resources by a partnership in 1830, but after the death of his partner in 1841 prosecuted the business alone with ample means. His establishment became one of the largest in the country, and he finished annually more than 1,500 instruments, and gave employment to about 500 operatives. His manufactory being burned one year before his death, at a loss of over \$200,000, he commenced a new and magnificent building, which was completed by his sons. Mr. Chickering's improvements, which have given the superiority to American pianos, have been generally adopted in this country and Europe.

CHICLANA, a town of Spain, in the province and 11 m. S. E. of the city of Cadiz; pop. about 9,000. It has a number of country residences belonging to the wealthy inhabitants of Cadiz, the workhouse of that city, a hospital, and a theatre. Near the town, on March 5, 1811, the battle of Barosa was fought between the Anglo-Spanish army under Sir Thomas Graham and the French under Victor.

CHICOPEE, a town of Hampden co., Mass., on the E. side of the Connecticut, at the mouth of the Chicopee river, 95 m. by rail W. S. W. of Boston; pop. in 1870, 9,607. It contains the villages of Chicopee or Cabotville and Chicopee Falls, which are connected by a branch railroad 2 m. long, uniting with the Connecticut River railroad at Chicopee. The town was settled about 1640, and formed the northern part of Springfield, and was set off from that city in 1848. The principal establishments are 7 cotton mills, with 114,208 spindles, 1 woolen mill, 1 manufactory of hollow ware and castings, 1 of locks, 2 of ploughs and other agricultural implements, 2 brass founderies (Ames company), 1 manufactory of military goods, &c., 1 of arms, and 1 brick yard. The chief companies are the Dwight manufacturing company (prints, sheetings, &c.), and the Ames manufacturing company, which makes machinery, bronze cannon, small arms, &c. The bronze doors of the senate wing of the capitol at Washington were cast by this company, as was also Ball's equestrian statue of Washington in the Boston public garden.

CHICORY. See CHICORY.

CHICOT, a S. E. county of Arkansas, bordering on Louisiana, and bounded E. by the Mis-

issippi river; area, 820 sq. m.; pop. in 1870, 7,214, of whom 5,399 were colored. It is intersected by Crooked and Mason bayous. The surface is level and in some places subject to inundation. The soil in several parts is very fertile. The chief productions in 1870 were 85,462 bushels of Indian corn, 5,092 of sweet potatoes, and 10,187 bales of cotton. There were 449 horses, 988 mules and asses, 1,005 milch cows, 2,073 other cattle, and 2,529 swine. Capital, Lake Village.

CHICOUTIMI, a N. county of the province of Quebec, Canada, intersected by the Saguenay, and containing besides the parishes a large unorganized territory; area, 23,759 sq. m.; pop. in 1871, 17,493, of whom 16,643 were of French origin, and 17,393 Roman Catholics. Much of the surface is rugged and uneven, though recent explorations give a better impression of its agricultural capabilities. The pine forests, which are of immense extent and great value, have been partially worked for several years. Vessels are freighted with timber for England at the town of Chicoutimi, the capital of the county, 75 m. up the Saguenay.

CHICOSI. See USUMASINTA.

CHIERI, a town of Italy, in the province and 9 m. S. E. of the city of Turin; pop. about 16,000. It has a gymnasium, a polytechnic school, and a collegiate church, which is believed to have originally been a temple of Minerva, with many beautiful paintings.

CHIETI, a province of Italy. See ABRUZZO CITERIORE.

CHIETH (anc. *Teate Marrucinorum*), a fortified city of Italy, capital of the province of Chieti or Abruzzo Citeriore, Italy, built on a hill, in the midst of a pleasant country near the Pescara, 96 m. E. N. E. of Rome; pop. in 1872, 23,602. It is the seat of an archbishopric, a high court of judiciary, a civil court, and of many wealthy families. The city contains five churches, a military hospital, a college and a religious seminary, several monasteries, wool and silk manufactories, and carries on a trade in the produce of the country. There are remains of a large theatre, some ruined temples, a gateway, and a mosaic pavement.—The ancient Teate was the capital of the tribe of the Marucini, and was one of the principal towns of this part of Italy. It joined the Samnite league, after the fall of which it was held successively by the Romans, Goths, Lombards, Franks, and Northmen. The order of Theatines or Chietines took its name from this place, its founder, Paul IV., having been archbishop of Chieti. It was taken by the French in 1802.

CHIGI, a family of Roman prelates and princes, who are hereditary marshals of the conclave. They originally came from Siena, where the Chigi-Zondadavi branch still exists. FABIO (1599–1667) became pope under the name of Alexander VII. and vastly increased the wealth and influence of his relatives, the magnificent Chigi palace and the extensive Chigi library in Rome still perpetuating the

memory of the family. They subsequently added the family name Albani of Pope Clement XI. to their own. The present head of the Chigi-Albani princes is Don SIGISMONDO, born Aug. 24, 1798. FLAVIO, a brother of Prince Sigismondo, and the present papal nuncio in Paris, born in 1810, was in 1848 an officer of the pope's body guard of nobles, and afterward took holy orders. On being appointed papal representative at the coronation of Alexander II. of Russia (Sept. 7, 1856), he received the title of archbishop of Mira *in partibus*. He was subsequently nuncio in Munich, and on Jan. 23, 1862, he was accredited in the same capacity in Paris.

CHIGO, a species of flea (*sarcopsylla penetrans*), called also jigger and sand flea, found in the West Indies and the tropical regions of South America. It inhabits the sand and chinks in the stalls of animals, and it is only the impregnated female that is found on man. She bores deeply into the skin of the feet in order to deposit her eggs, and as soon as an attachment is obtained, her hindmost segment swells up in a wonderful manner beneath the skin, so that the thorax and head appear as appendages to a bladder often as large as a pea. This sac contains the eggs or larvæ,

1. Chigo, magnified. 2. Chigo gorged with blood.

about 60 in number, which, if the sac be broken during removal, are scattered through the tissues, and give rise to troublesome ulcers, which may necessitate amputation. Its removal unbroken may be effected with a needle, as soon as the swelling takes place. The negroes, and others going without shoes and stockings, are liable to suffer from this insect; and some of them acquire much dexterity in its removal. The best preventive is cleanliness and the constant wearing of shoes.

CHIHUAHUA. I. A N. state of Mexico, bounded N. by New Mexico and Texas, E. by Coahuila, S. by Durango, and W. by Sinaloa and Sonora, between lat. 26° 30' and 31° 45' N., and lon. 103° 50' and 108° 40' W.; area, 105,295 sq. m.; pop. 180,000. A prolongation of the Sierra Madre covers the western portion of the state, the mountains being in some parts little short of 180 m. in breadth. The mountain passes and fastnesses are frequented by savage Indians. The plains maintain an average elevation of from 4,000 to 5,000 ft., while the mountain systems by which they are traversed rarely rise to a greater altitude than 1,000 ft. above them, until by a gradual slope upward

the Sierra Madre is reached, some of the peaks of which attain 8,000 ft. The Rio Grande del Norte serves as the dividing line with the United States. The Conchos and the Verde are the other important rivers. The soil, especially in the northern districts, is in general stony and unfavorable to vegetation. But the valleys are very fertile, and support large herds of cattle; and the region bordering the eastern slope of the Sierra Madre is well watered, and is reputed to possess the richest soil in the state. The vine is cultivated with some success; cotton is raised, though to no considerable extent; and the chief resources of the people are their cattle, sheep, horses, and mules, all of which they export in large numbers. Gold, silver, copper, iron, tin, lead and other minerals abound, especially silver, for which the Chihuahua mines have been celebrated for centuries. The most productive silver mines were those of Batopilas, Jesus Maria, and El Parral, in the Sierra Madre, and those of Sta. Eulalia, in the plain a few miles distant from Chihuahua city. The region adjacent to the boundary line with the state of Sonora is interesting as the site of extensive ruins. (See CASAS GRANDES.) Wild animals abound, including black and grisly bears, the buffalo, the elk and other deer, the puma, ounce, and wild boar. The state is infested by tarantulas and scorpions, and there are four species of serpents. **II.** A city, capital of the state, and of a district of the same name, situated at the base of the Sierra Madre, in a beautiful plain, 800 m. N. W. of Mexico, in lat. 28° 35' N., lon. 105° 30' W.; pop. about 12,000. The most noteworthy public edifices are the magnificent cathedral, situated in the Plaza Mayor, constructed of hewn stone, at a cost of \$800,000; the mint; the prison, formerly a convent of the Jesuits; and the handsome aqueduct by which the city is supplied with water. In the Plazuela de San Felipe is a monument commemorative of the execution on the same spot of the first heroes of Mexican independence; and there are two hospitals, a house of correction, a military and several other schools. Chihuahua was founded in 1691, and erected into a town in 1718, when it is said to have had over 70,000 inhabitants.

CHILBLAIN, an atonic inflammation or chronic engorgement of the skin and subcutaneous or cellular tissue, caused by sudden alternations of temperature, generally by exposing the hands and feet when benumbed with cold to too great heat. As it usually appears, the skin is reddened and somewhat swelled, painful on pressure, with considerable tingling and itching. It is most frequently seen on the toes, heel, and ball of the foot, and appears only during the winter season. The treatment consists in stimulating lotions, such as salt and water, or tincture of iodine.

CHILD, Sir Josiah, an English merchant, born in London in 1630, died there in 1699. He was for some time chairman of the East India company, and wrote several papers, without

signature, in defence of the traffic with the East. In his essay on trade he advocated the compulsory emigration of paupers to the colonies. His principal work is entitled "Brief Observations concerning Trade and the Interest of Money, by J. C." (4to, London, 1668). An enlarged edition was published in 1690, under the title of "A New Discourse on Trade." The work has been several times reprinted. It was written in defence of the reduction, by legal enactment, of the rate of interest on money from 8 to 6 per cent., and recommends a further diminution to 4 per cent. Charles II. made him a baronet. His son became Viscount Castlemaine and Earl Tynley, but the peerage expired with the second earl.

CHILD, Lydia Maria, an American authoress, born at Medford, Mass., Feb. 11, 1802. Her father, David Francis, was a baker. In 1824 she published her first book, "Hobomok, an Indian Story," which was followed the next year by "The Rebels, a Tale of the Revolution." The scene was laid in Massachusetts, and some of the characters were the historical men of that period. The book for several years held its place as a standard novel, the times and the events with which it dealt giving it a strong hold upon the popular esteem. A speech which she put into the mouth of James Otis was believed by many to have been actually delivered by him. A sermon of Whitefield's was also given, which was inserted in the New England school reading books as a genuine sermon of the great preacher. In 1826 she commenced the "Juvenile Miscellany," a monthly magazine, which for eight years was under her management. She published a cookery book, under the title of "The American Frugal Housewife," which later publications upon the same subject have not displaced. In October, 1828, she was married to David Lee Child, a lawyer of Boston. "The Girls' Own Book" and "The Mothers' Book" (1831) testified to her strong interest in practical education. About this time the anti-slavery movement was commenced in Boston, and Mrs. Child identified herself with it at the beginning. One of the first distinctive anti-slavery books was her "Appeal in behalf of that class of Americans called Africans," in which she advocated the immediate emancipation of the blacks. This is her largest and most comprehensive work upon the subject of slavery; but it was followed in subsequent years by various smaller publications of a similar character. In 1836 she published "Philothea," a Grecian romance of the time of Pericles and Aspasia. In 1841 she removed to New York to take charge as editor of the "National Anti-Slavery Standard," of which she remained editor, assisted by Mr. Child, for two years. In its columns she commenced a series of "Letters from New York," which, with others written subsequently, were collected in two volumes (1843-'4). She afterward published "History of the Condition of Women in all Ages and

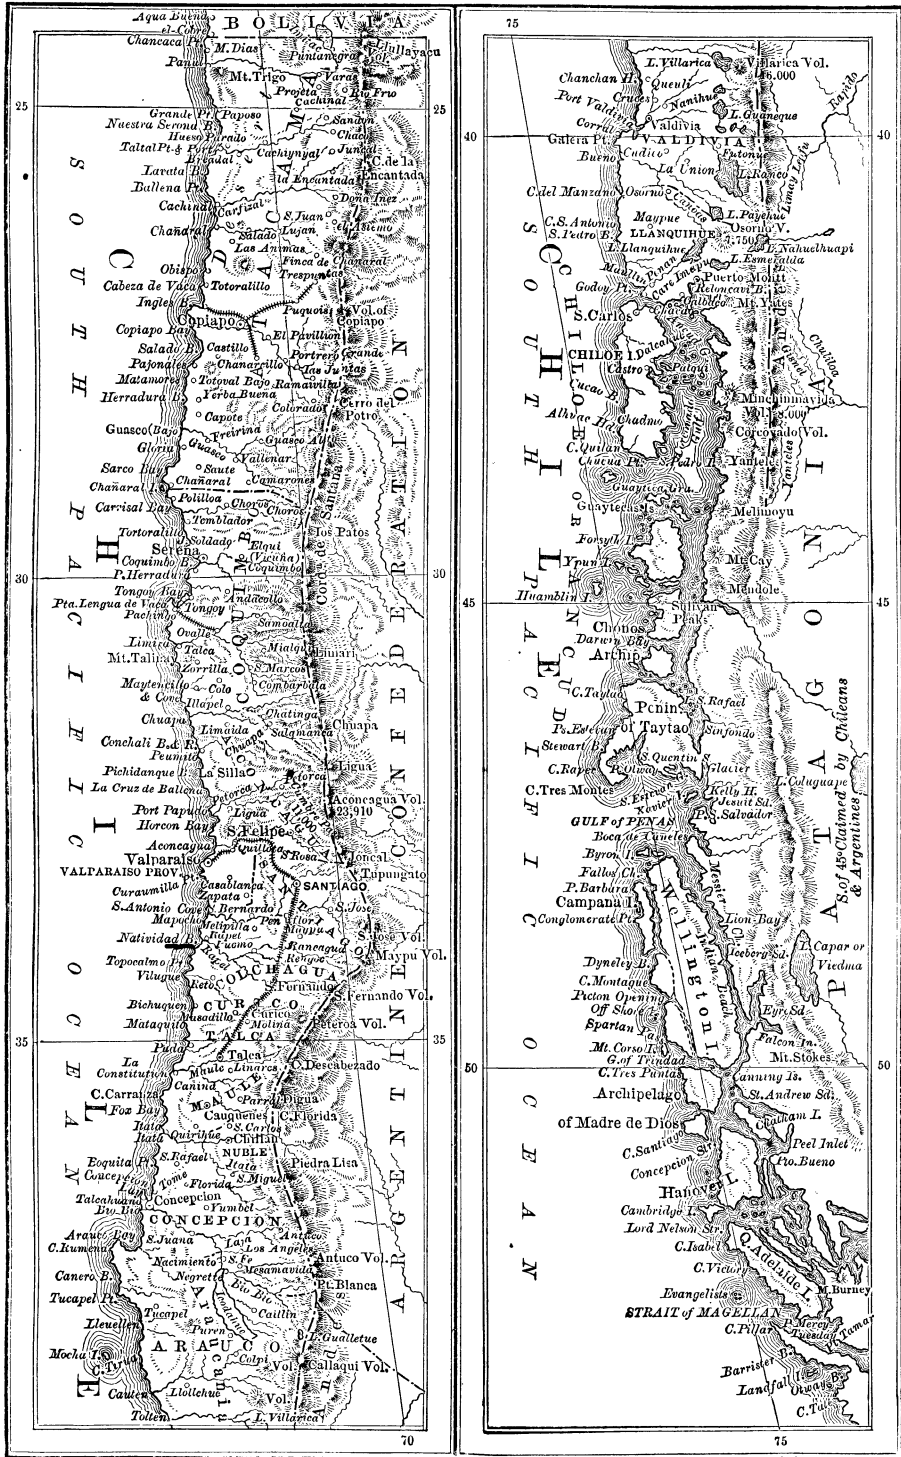

Nations" (2 vols., 1845), "Biographies of Good Wives" (1846), and several volumes of stories for children. In 1859 she wrote a letter of sympathy to John Brown, which involved her in a correspondence with Gov. Wise and Mrs. Mason of Virginia. This correspondence was published in a pamphlet of which 300,000 copies were circulated. Her other works are: "Life of Isaac T. Hopper" (1853); "Progress of Religious Ideas" (3 vols., 1855); "Autumnal Leaves" (1857); "Looking toward Sunset" (1860); "The Freedman's Book" (1865); and "A Romance of the Republic" (1867).

CHILDBIRTH. See OBSTETRICS.

CHILDEBERT, a Merovingian king of the Franks, the third son of Clovis and the second of Clotilda, born about 495, died in 558. On the death of his father in 511 he became king of Paris as his share of the patrimony, while Clodomir became king of Orleans and Clotaire king of Soissons. In alliance with his brothers he participated in the conquest of Burgundy, and subsequently successfully conspired with Clotaire to usurp the kingdom of their brother Clodomir, who had been killed in the Burgundian war. He afterward made some conquests in Spain. On his return he quarrelled with Clotaire and made war on him; but before the contest ended he died, and having no male heir his kingdom fell to Clotaire. Two other Merovingian Childeberts are to be found among the *rois fainéants*.

CHILDREN, John George, an English electrician, born at Ferox Hall, Tunbridge, May 18, 1777, died Jan. 1, 1852. He was educated at Cambridge for the church, but his wife dying, he travelled for some time in the south of Europe and the United States, and then devoted himself wholly to scientific pursuits. In 1808 he published in the "Philosophical Transactions" an account of a series of experiments confirmatory of Davy's view that electric intensity increases with the number of voltaic plates, and the quantity of electricity with the extent of surface. In 1815 he continued the subject in the "Philosophical Transactions," relating among other interesting results the conversion of iron into steel by union with diamond. Subsequently he discovered a method of extracting silver from its ore without amalgamation. Besides the papers above mentioned, he published translations of Berzelius "On the Blowpipe," and Thénard "On Chemical Analysis;" he also assisted to establish and edit the "Zoological Journal." He was for some years secretary of the royal society, and one of the librarians of the natural history department in the British museum.

CHILI, or **Chile**, a republic of South America, lying W. of the Andes, between lat. 24° and 56° S., and lon. 70° and 74° W. It is bounded N. by Bolivia, E. by the Argentine Republic and Patagonia, S. and W. by the Pacific ocean. These limits include that part of Patagonia W. of the Andes and S. of lat. 43° 20', over which the jurisdiction of the Chilean government is

at present merely nominal. The area, exclusive of Patagonia, is about 133,000 sq. m.; including it about 250,000 sq. m. The surface is greatly diversified. Besides the Andes, which form its E. border, there are two other ranges, of less elevation, which traverse portions of the narrow strip between the Andes and the Pacific, commencing near the 33d parallel. The more easterly of these is known as the central chain; it terminates on the Pacific, opposite the N. end of the island of Chiloe. The other, known as *la cordillera de la costa*, or the coast range, separating from the central near its origin, follows more nearly the line of the coast. It is of lower elevation than the central range, and is in some parts arable. Besides these mountain chains, there are multitudes of isolated hills. The principal valley of the country is that between the central chain and the Andes. The mean elevation of the mountains of Chili is from 13,000 to 14,000 ft. The most of them are now, or have been at some former time, volcanic. The highest peak, Aconcagua (22,422 ft., according to Pissis), shows no sign of modern igneous action; but Llullaillaco (21,000), Villarica, San José (18,150), Peteroa, Llayma, Antuco, Hanahue, Chillan, Calbuco, Corcovado, Osomo, Yantéles, Minchinmadom, and several others, are, or have been within a late period, active volcanoes. Besides these, the following, which are not volcanoes, are remarkable for their elevation: Cerro del Mercedario (22,305 ft., Pissis), Tupungato (21,413, Pissis; 22,450, Gilliss), Cerro de la Ramada (20,824, Pissis), Joncal (20,368, Gilliss), Cerro del Plomo (17,825), Maypu (17,664), Cruz de Piedra (17,126), San Francisco (16,998), Cordillera de la Laguna (15,575), and Descabezado (13,100). In the northern portion, the coast and central Cordilleras spread out into the elevated plateau known as the desert of Atacama, which rises rapidly from the coast to a height varying from 4,000 to 10,000 ft., and from the comparatively level surface of which shoot up mountain peaks of great elevation, and often volcanic. There are 10 passes across the Andes, from the Argentine Republic: 1, from Antofagasta in Catamarca, through the Portezuela de Come Cavallo, to Huasco and Copiapó, about 14,500 ft. above the sea; 2, from San Juan, over the Portezuela de la Laguna, to Coquimbo, 15,575 ft.; 3, pass of Los Patos, on the N. side of the Aconcagua; 4, the pass of La Cumbre, from Mendoza, by way of Uspallata to Santiago, 445 m., 12,530 ft., passable from November to May; 5, the Dehesa pass, near Tupungato, seldom used; 6, the Portillo pass, much used from the beginning of February to the end of April, from Mendoza to the valley of the Maypu river; 7, the pass of La Cruz de la Piedra, leading into the Portillo road on the western slope of the Andes; 8, the pass of Las Damas (highest point 11,600 ft.), 9, the Planchon pass, along the Claro and Teno rivers to Curico, 6,600 ft., which has been surveyed

for a proposed railway across the mountains; 10, the pass of Antuco, on the road from Concepcion. A new pass has recently been discovered by Germans travelling from Chili to Patagonia.—Chili belongs to the basin of the Pacific, excepting the valley of Uspallata, the waters of which flow toward the Atlantic. The rivers are all of inconsiderable length, but when swollen by the melting of the snows they discharge large amounts of water, and of alluvium, into the Pacific; and almost all of them have in consequence considerable bars at their mouths. The Biobio rises in an extinct volcano in the extreme E. of the Andes, lat. $38^{\circ} 15'$, and takes a general N. W. direction, and after a course of about 200 m. falls into the Pacific at Concepcion. It has a sand bar at its mouth, which prevents vessels of any considerable draught of water from ascending it; but it is navigable as far as Nacimiento, nearly 100 m. The Maule rises in the Andes, in lat. $35^{\circ} 10'$, and has a nearly due W. course of about 150 m.; it is navigable for small craft about 70 m. The Valdivia rises in Lake Guanegue, in lat. $39^{\circ} 45'$, and has a W. S. W. course; its length is about 100 m., and it is navigable for 50 m. The other considerable streams, few of which are navigable, are the Imperial, the Tolten, the Bueno, the Itata, the Maypu, the Rapel, the Aconcagua, the Mataquito, the Limari, the Coquimbo, the Huasco, and the Copiapó. The last is often dry in summer.—Chili has numerous lakes, particularly in the southern provinces, but few of them are large. In some near the coast the water is brackish, but the most of them are bodies of fresh water, accumulated in the elevated valleys. They all abound in fish. The largest of the fresh lakes are Llanquihue, in the province of the same name, and Villarica, in the province of Valdivia, the former of which is 30 m. long and 22 in its greatest breadth. Villarica covers more than 100 sq. m. Todos los Santos or Esmeralda, and Rupanco, in the same plain, are respectively 18 and 24 m. long. In the province of Concepcion are Guilletue, with a surface of about 50 sq. m., and La Laja, celebrated for its picturesque scenery and the beautiful fall at its outlet.—There are few good harbors. The best is that of Talcahuano, which is well protected, and with ample room and depth of water. Coquimbo is the next harbor in point of safety. The harbor of Valparaiso though exposed, is the most important on the Chilian coast in the extent of its commerce. The other principal harbors are Caldera, the port of Copiapó, lat. $27^{\circ} S.$, from which the largest exports from the silver and copper mines are shipped; Constitucion, within the mouth of the river Maule, Valdivia, an excellent harbor for small vessels; and San Carlos, on the island of Chiloe, lat. $41^{\circ} 51'$.—Of the numerous islands belonging to Chili, the most important are those of Chiloe and its archipelago, more than 60 in number, of which 30 are settled and have harbors. They abound in seals, otters, and

shell fish, and are well supplied with wood and water. (See CHILOE.) Southward of these are the Guaytecas group and Huafo, similar in their general character. On the coast above Chiloe are several smaller islands, the principal of which are Mocha, lat. $38^{\circ} 23'$, Santa Maria, lat. $37^{\circ} 3'$, and Quiriquina, in the mouth of Concepcion bay, all of which have within the past 100 years met with extraordinary physical changes, from the earthquakes so common on the coast. The most famous of the Chilian islands is the group called Juan Fernandez. (See JUAN FERNANDEZ.)—The climate of Chili is one of the finest on the globe. Being in the south temperate zone, its summer answers to our winter, December, January, and February being the hottest months. During three months little or no rain falls, and the thermometer sometimes rises to 90° or 95° F.; but the sea breeze at night cools the earth, and renders the temperature refreshing. The mean temperature of the winter months at Valparaiso is 54° , at La Serena 54.8° , at Santiago 49° , at Valdivia 46.8° . The highest temperature known at Santiago is 90° , the lowest 47.5° . At Valparaiso the highest mean point in summer in three years' observation was 78° , the lowest 62° , and the annual mean 70.8° . At Coquimbo the mean summer temperature was 63.6° , and the entire range only 16.8° . At Concepcion the mean summer temperature at 3 P. M. was 73.5° , the mean for the year about 56° . In Valdivia the mean summer temperature is 60° , that of the year 55° . At Santiago the average number of hours during which rain fell in the year, during 26 years' observation, was $215\frac{1}{2}$, or about 9 days. Further south the quantity of rain is somewhat greater. Toward the north, on the contrary, the rain diminishes in quantity, and on the desert of Atacama seldom or never falls. As a result of this equable and uniform climate, trees, fruits, and flowers of both tropical and temperate regions flourish well. "The native palm and pine of Araucania," says Lieut. Gilliss, "the cherimoya of tropical America and the medlar of Japan, the magnolia of Florida and the olive of Asia, may all be found within the compass of a garden, not less luxuriant in their proportions and ever verdant foliage than under the climes of their origin." The atmosphere is remarkably clear, especially at night. It is estimated that a $6\frac{1}{2}$ -inch achromatic telescope at Santiago is fully equal to a $12\frac{1}{2}$ -inch one at the Cape of Good Hope. The crescent of Venus was more than once seen with the naked eye by Lieuts. Gilliss and Macrae. There are two drawbacks to this delightful climate, the violent winds and hurricanes which occur at some seasons, and the earthquakes. During the summer months northerly winds, known as *temporales*, occasionally blow in violent gusts, sometimes for two or three days, and are then followed by several weeks of pleasant weather. There is usually a fresh breeze from the S. W. between the hours of

10 and 3 in the day during the summer, and the force of this breeze on the mountains is terrific. The climate, though so delightful, seems to predispose the inhabitants to apathy and indolence. The Chilians are not a long-lived people; pulmonary diseases, affections of the heart and liver, and epidemic dysentery prove fatal to great numbers, and reduce the average duration of human life there to a lower point than in more variable climates. How far these diseases may be dependent on other causes than climate is difficult to ascertain.—Chili may with propriety be called the land of earthquakes, for it is probably visited by more than any other known region of the earth. The inhabitants have two words by which they designate the phenomena: *temblores*, slight and partial agitations of the surface, and *terremotos*, or violent upheavings and oscillations. The *temblores* are so frequent as to pass unnoticed. The record of 25 months' observation at La Serena, in the province of Coquimbo, between 1849 and 1852, shows 156 shocks in that period, though the great earthquake of April, 1851, and the repeated shocks which followed, were not included. Of these not more than two or three could be put down as *terremotos*. At Santiago, in 32 months, there were 130, of which four were very severe. The number increases in a rapid ratio as the observer proceeds northward, though in general those of central Chili are most severe. Of the great earthquakes, 16 of peculiar severity are recorded, in nearly all of which there was considerable destruction of life and property. In that of 1570, which destroyed Concepcion, 2,000 persons perished; and in that of 1647, which destroyed Santiago, 1,000 persons and 60,000 head of cattle. The great earthquake of 1730 destroyed Valparaiso, La Serena, Concepcion, Coquimbo, and every village on the coast between Concepcion and Coquimbo, and in Santiago over 100 persons lost their lives. In 1835 Concepcion was a fourth time destroyed, and Talcahuana, Los Angeles, Yumbel, Cauquenes, and Constitution were levelled, and about 200 persons were killed; in 1837 the city of Valdivia was destroyed; and in 1851 a great number of persons and churches were injured at Santiago, Valparaiso, and many of the intervening villages. In 1871, March 25, occurred a very severe shock, by which much property was destroyed at Valparaiso and Santiago, but no lives were lost.—The topographical structure of Chili implies the continuation of similar geological formations in a N. and S. direction, following the range of its mountain chains. The belt of country between the Andes and the coast, ranging from 80 to 100 m. in width, is traversed, S. of lat. 32° , by numerous longitudinal ridges, called the Cordilleras of the coast, which are granitic. Further N. these spurs are more irregular in their direction, and are covered in great part with barren sands, showing no trace of vegetation. This northern

portion is of importance for its valuable mines, while a strip along the S. coast, from Concepcion to the island of Chiloe, contains the principal mines of bituminous coal worked in South America. The country between the Andes and the coast is particularly interesting to geologists for the evidences it presents of several successive elevations which it has experienced within modern times. Some of these are historical, as that of 1822, when the coast at Valparaiso, and for many leagues N. and S. of it, was uplifted about 6 ft. The bed of shells and sea pebbles which marked its former beach is now that distance above the reach of the highest tides; and a succession of similar collections of shells of species belonging to the coast, accompanying terraces found further inland, and at higher levels, indicate as many as five uplifts of this character, but of much greater height, the difference of level between two terraces being found 120 ft. and between the next two 182 ft. Around the bay of Coquimbo these terraces are most distinctly marked in the hills; and as they extend back into the country they spread out into plains, upon which the towns are built. Near Valparaiso comminuted sea shells of living species are found at elevations of over 550 ft.; and some, it is stated, have been met with even 1,300 ft. above the sea level.—Chili abounds in mineral wealth. Among the metals are gold, silver, copper, lead, tin, iron, zinc, nickel, cinnabar, cobalt, antimony, bismuth, manganese, and arsenic. The copper and silver mines are probably the richest in the world, and gold exists in very considerable quantities. The principal mining region is in the north, chiefly in the province of Atacama, but rich deposits are continually discovered in the different mountain ranges further south. Copper exists along the course of the granitic and metamorphic rocks of the coast range and western spurs of the Andes, from Santiago to the northern extremity of the country, and beyond into Bolivia and Peru. The region about Copiapó has been worked the longest, and many new mines are opened there every year. Rich deposits of silver and copper have lately been discovered in the province of Coquimbo. Copper is the chief mineral product, the annual value of the exports being over \$12,000,000. The other metals, though abundant, are little sought after. Cinnabar was once mined to some extent, but its importance is now greatly reduced by the cheaper production of quicksilver in California. Besides the metals, Chili contains other valuable minerals. Sulphur, salt, nitre, and alum are plentiful, gypsum and limestone abound, and a fair quality of bituminous coal, of a dull black color, is found near Concepcion and at other points along the coast. These coal beds were known as early as 1825. In 1841 the formation was traced between Talcahuano and Valparaiso, and mines were soon after opened at the former locality. The coal has

also been found in abundance near the mouth of the Laraquita, and the beds are visible in the cliffs from vessels sailing along the coast. New mines have been opened lately along the gulf of Arauco, and large deposits have been discovered in Cobquecura. The most productive mines are in the districts of Coronel and Lota, the latter 30 m. S. of the Biobio, in the province of Concepcion. The coal beds are contained in strata supposed to be of the tertiary formation; and though the coal of this age is never so good as that of the true coal measures, that of Chili is found to answer for steam and domestic purposes; it is considered unsuitable for smelting copper ores. By analysis specimens of this coal afforded 67.62 per cent. of carbon, showing a decided superiority over the ordinary brown coal of the tertiary. Reports of examinations of other coals of the region represent, however, a percentage of carbon not exceeding 40, and the presence of much iron pyrites. The most noted mineral springs are those of Apoquindo, Colina, Cauquenes, Panimavila, Mondaca, Cato, Soco, and Doña Ana; the principal constituents of which are chloride of calcium, chloride of sodium, chloride of magnesium, and sulphates of soda and lime, with occasional traces of iron and alumina. About 75 m. E. S. E. of Chillan hot sulphur springs are found almost up to the line of perpetual snow on the Nevado de Chillan. They are much frequented, and are reputed to possess extraordinary medicinal virtues.—A large part of the soil of Chili is unproductive. The extensive portions of its surface covered by lofty and precipitous mountains, too cold for vegetation, or too scantily covered with earth to sustain it; the deserts of the north, where rain never falls; the large tracts covered by the primitive forest; and the districts inhabited by warlike Indian tribes, must all be deducted from that fit for cultivation; and the remainder forms but a small fraction of the area. Yet the soil, when capable of tillage, is so fertile and yields crops so abundant, that Chili exports very considerable amounts of cereals and meats. Of its provinces, Atacama and Coquimbo do not produce a sufficiency of grain or cattle for home consumption; but the others not only supply themselves and these, but raise a large surplus. The principal grains are wheat, barley, oats, and maize; rye does well, but is not raised because there is no demand for it. Superior hemp is produced in the country north of the Maypu. Beans are a very large and important crop, and peas are extensively cultivated. In the southern provinces potatoes of excellent quality are produced. Fruits abound, including apples, pears, peaches, oranges, limes, nectarines, plums, apricots, figs, grapes, and cherries. Melons, squashes, and gourds also grow to perfection. In the south of Chili a profuse vegetation prevails. The sides of the mountains are covered with herbaceous plants and with flowers of the richest hues, and dense forests abound. This verdure

lasts only about five months, from May to October; at other times the country has a barren appearance, and furnishes an inadequate supply of food for cattle, so that beef and mutton are of inferior quality. In the southern provinces large quantities of timber, valuable for building and ornamental purposes, are produced. Evergreens attain a gigantic size. The araucaria, a species of pine, the alerce, a cypress with a dark rich heart-wood, the roble, tiqui, mañu, muermo, and mayten are all valuable and durable woods. The coligue, a species of bamboo, is in very considerable demand for thatching roofs.—The animals of Chili are not as numerous as those of the countries east of the Andes. The mammals are comparatively few. Claude Gay, the eminent naturalist, enumerates seven species of *cheiroptera*, mostly of the bat tribe; 12 of *carnivora*, embracing four of the cat tribe, three foxes, one weasel, two polecats, the nutria, and the otter; six species of the *phocidæ*, embracing the seal and his congeners; one marsupial, the *didelphys elegans*, peculiar to Chili; 12 genera and 25 species of rodents, of which 12 belong to the *muridae* family; the chinchilla and its congeners, and the cavy or mountain rabbit. There are only two species of the *edentata*, the *dasybus* and *pichiciego*, the latter a very rare animal, found only in Chili. There are three ruminants, the guanaco, the largest of the llama tribe, and two of the deer tribe, the pudu and the güamul. There are four species of *cetacea*, two dolphins, the sperm whale, and the right whale. There are 11 species of *reptilia*, five of which are saurians, four ophidians, one frog, and one toad. The birds are more numerous. The *raptores*, embracing the condor, the vultures, hawks, and owls, are largely represented. The great order of *incessores* has numerous representatives of its every tribe and family, many of them of superb plumage, and some of wonderful powers of song. The dove and pigeon tribes are also found in considerable numbers, and the waders (*grallatores*) and swimmers (*natatores*) are almost numberless, several of the species being peculiar to the western coast of South America. Among the fishes, there are three species of the perch tribe, all new; one of the *atherinidæ*, the kingfish; three of the *siluridæ*, one a new genus; two *clupeidæ*, both new, one a new species of the shad; one *cheirodon*, a new genus of the *characini* family; and a new myxinoïd, having an affinity with the lamprey eel of our northern waters. Crustaceans and mollusks are abundant, especially in Chiloe and the other southern provinces, but have not been very fully examined. The chonos, a peculiar species of oyster, exists in great quantities along the coast, and forms a favorite dish. Among the domestic animals, cattle are raised in large numbers. The horses are hardy and capable of great endurance. Mules and asses are excellent. Sheep, goats, and hogs abound, but are of poor quality.—

Chili is divided into 15 provinces and one colony. The following table shows the estimated area and population of the provinces, exclusive of Patagonia, in 1870:

PROVINCES.	Area.	Population.
Aconcagua	6,000	184,178
Arauco	13,800	87,677
Atacama	38,000	83,343
Chiloe	9,050	62,958
Colchagua	3,900	153,096
Concepcion	3,600	155,382
Coquimbo	13,300	159,695
Curicó	3,000	100,200
Llanquihue	8,850	43,342
Maule	6,400	211,567
Nuble	3,700	125,519
Santiago	7,800	374,078
Talca	3,600	107,412
Valdivia	10,700	27,980
Valparaiso	1,670	144,954
Colony of Magellan	?	729
Total	132,870	1,972,438

The foreign population numbers about 25,000, of whom over one half belong to the Argentine Republic and other neighboring states. The remainder are chiefly English, Germans, French, Americans, Spanish, Portuguese, and Italians, with a few Chinese. Santiago, the capital, had in 1865 a population of 115,377; Valparaiso, 70,438; Talca, 17,900; Concepcion, 13,958; La Serena, 13,550; Copiapó, 13,381; Chillan Nuevo, 9,781; and San Felipe, 8,696. In the above estimate of the total population, the warlike aborigines, nominally under the jurisdiction of Chili, are not included. They are supposed to number about 75,000. These alone, of all the American tribes who came in contact with the Spanish or Portuguese invaders, have maintained their independence, notwithstanding a war of extermination was waged against them for a century and a half. (See ARAUCANIANS.) Of the other inhabitants of Chili, the Chilenos, as they call themselves, not more than a third, and perhaps not more than a quarter, are of pure Spanish descent; the greater part are of mixed blood, as their forms, features, and hair testify. South of the Biobio there are considerable numbers of Indians who have been reduced to subjection, and are employed as peons or farm laborers, and sometimes, though rarely, as *inquilinos* or tenants on the *haciendadas* or large farms of that region, rendering a kind of feudal service, and making their payments of rent in labor or in kind. The Chilians are more enterprising than the inhabitants of most of the South American states, and the *hacendados* (planters) and merchants often accumulate large amounts of property. With the exception of those destined for the learned professions, they have generally but little education. The men are usually slender, and to the casual observer appear wanting in muscular development; but Lieut. Gilliss affirms that they possess much more strength than the men of other nations. The women, who are generally pretty, have fuller and rounder figures, and seem to have more intelligence

than the males. The dress of the Chilians of the higher classes is in the French style, except that the poncho (a blanket, with a hole in the centre for the head to pass through) is in universal use with both rich and poor. The ladies also copy the French fashions, except in a constant use of the shawl, both indoors and out. The poorer classes dress more like the gauchos of the eastern states of South America. In manners they are gay, social, hospitable, and generous, but retain in some degree the bigotry and indolence of their Spanish ancestry. Crimes are of comparatively rare occurrence, but gambling is an almost universal passion. The *chicha*, a fermented liquor made from grapes, green apples, and other fruits, and very intoxicating, is a constant drink, and often inflames the passions of the lower classes and the Indians to fury. Licentiousness exists to an alarming extent, and the diseases it engenders are among the most fatal in the country. Illegitimacy is common. In Santiago a fifth, and in Valparaiso a quarter of all the births are illegitimate. Blindness and goitre are very common. The religion of Chili is Roman Catholic, and the laws tolerate no other; but in practice there is no very marked opposition to the quiet performance of worship under other forms of faith.—Within a few years the government has devoted much attention to the subject of education, and now no other South American state has so efficient an educational system. New schools and colleges have been established, and a strong effort has been made to extend their benefits to all classes. There are now more than 500 government schools, and as many municipal, private, and monastic, with an aggregate attendance of nearly 40,000 scholars. The books for the government schools are furnished by the republic. There are two normal schools for the education of teachers, one for males, the other for females. The national institute at Santiago, which is the government university, is divided into two sections, the preparatory and the university. The preparatory section has two courses, that of the humanities, occupying six terms, and that of mathematics, occupying five. Instruction in both sections is free. Another institution, called the conciliar seminary, combines the college and theological seminary. There are also at the capital a school of agriculture, a naval school under the direction of the minister of marine, and a military school under the care of the minister of war. The national library, also at the capital, contains about 25,000 volumes, and is especially rich in theological works, having been originally founded by the Jesuits.—The agriculture of Chili is very primitive. With the exception of a tolerably skilful system of irrigation, the farmers and planters are grossly ignorant of the improved methods. Their ploughs are rude instruments, only scratching the earth to the depth of two or three inches. The yoke is fastened to the horns instead of the neck of the

cattle. Of subsoiling, the application of manures, underdraining, and rotation of crops, they know nothing; and the stubborn adherence of the peons to old methods handed down from one generation to another is a barrier to any considerable improvement. Still, with all these drawbacks, so fertile is the soil, and so much is it enriched by the detritus brought down by the mountain streams, that agriculture is a very profitable pursuit. The farms are usually very large, frequently comprising several thousand acres; and herds of cattle 5,000, 10,000, or 20,000 in number are pastured on the elevated plains, and tended by the gauchos, till the period for their slaughter arrives. The hacendados usually reside in the cities, leaving their plantations under the care of mayordomos or overseers, and only visiting them occasionally. Smaller estates are called *chacararas haciendas* and also *haciendas*, and the small farms are called *quintas*. In the northern portions the population is far more laborious than in the southern, where few laborers are to be found above the age of 22. In the southern provinces, as soon as the young men marry they yearn for independence and live upon a little patch of land, which is generally presented to them by the planters. This class of laborers are attached to the plantation, and are called *inquilinos*. In consideration of the land and accommodation granted to them, they are bound to assist the planter during the *rodeos* (cattle fair) and the *trilla* (threshing season).—The manufactures of Chili are not extensive, but are increasing under the patronage of the government, which has endeavored to introduce them by offering exclusive privileges. Among them are hempen cloths, cordage, soap, tallow, leather, charcoal, flour, brandy, the coarser kinds of work in gold, silver, copper and iron, earthenware jars of a superior description, and ponchos. The latter, though woven in the rudest looms, possess some qualities which the French and English goods have never been able to attain. *Charqui*, or beef dried in the sun, is also produced in considerable quantities.—The greater part of the foreign trade of Chili is with Great Britain. The articles most extensively exported are copper, silver, wheat, flour, barley, hides, and wool; and the imports include nearly every variety of manufactures and foreign products. The total value of the exports for 1870 is shown in the following table:

Countries.	Value.	Countries.	Value.
Peru.....	\$5,220,000	France.....	\$1,750,000
Uruguay.....	940,000	Germany.....	130,000
Argentine Repub.....	80,000	Belgium.....	20,000
Bolivia.....	830,000	Other European	
Brazil.....	100,000	countries.....	10,000
Central America..	80,000	Countries not enu-	
United States....	350,000	merated.....	800,000
Other American			
countries.....	270,000	Total.....	\$27,060,000
Great Britain.....	16,450,000		

The value of imports for 1870 was as follows:

Countries.	Value.	Countries.	Value.
Peru.....	\$1,470,000	Great Britain.....	\$12,760,000
Uruguay.....	30,000	France.....	6,050,000
Argentine Repub.	820,000	Germany.....	2,690,000
Bolivia.....	160,000	Belgium.....	670,000
Brazil.....	550,000	Various European	
Central America..	170,000	States.....	350,000
United States.....	1,980,000	Asia.....	200,000
Other countries of			
America.....	400,000	Total.....	\$28,300,000

In 1871 the total imports from Great Britain amounted to \$12,814,900, and the total exports to Great Britain to \$18,403,067. The commercial intercourse of Chili with the United States has been very variable. In the earlier years of Californian emigration she sent large quantities of flour, grain, and lumber to that state, and took freely of our goods in return. Since that time her exports to this country have continued in large amount, but she receives little except money in return, the balances being mostly settled in Europe, where she is a debtor. In 1871 the exports to the United States were \$1,581,519, and the imports \$716,544; in 1872, exports \$1,849,880, imports \$721,799.—The government of Chili is nominally republican, and its offices elective; but practically it has been hitherto little more than a dictatorship, in which, while the forms of the constitution were tolerably preserved, the legislative, executive, and judicial functions were exercised by the party who had succeeded in seizing the reins of government. The president is elected for five years, and is eligible for a second term, but not for a third until a period of five years has elapsed. He is chosen by indirect election. The people nominate their delegates by ballot, and the latter appoint the chief of the state. The votes are examined and the declaration of the poll takes place at a meeting of the two houses of the legislature. The president is assisted by a council of state composed of 13 persons, all of his own choosing, and removable at his will, of whom, however, four must be heads of departments. The legislature consists of a senate of 20 members, elected for nine years, one third of whom go out of office every three years, and a house of deputies, consisting of one for every 20,000 inhabitants, elected for three years. Government officers may be members of either branch of the legislature, and still hold their offices. They may also represent more than one constituency. The election of the legislature is usually entirely in the hands of government, the mass of voters being the members of the national guard, who are appointees of the president, and the laborers and peons of the plantations and mines, who are entirely under the control of the wealthy proprietors, whose interests are the same as those of the president. For foreigners to obtain citizenship, ten years' residence is required if unmarried; if married, six years; if married to Chilenas, three years. The judiciary consists of primary courts, three courts of appeal, and a supreme court. The judges of the higher courts are appointed for life, or rather during good behavior, and can

only be removed by impeachment. There are four cabinet ministers: of foreign and home affairs, of finance, of war and marine, of religion and education. They are responsible for every official act, and cannot leave the country for six months after the expiration of their term of public service. No order or document from the president is legal without the counter-signature of the minister to whose department it belongs. Slavery is prohibited by law, and every person who treads the soil is declared free. In 1871 the standing army consisted of 2,400 foot, 712 horse, 804 artillery, 6 generals, 38 lieutenant colonels, 54 majors, 141 captains, and 256 lieutenants; total, 3,916 men and 540 officers, 165 of the latter belonging to the national guard. The latter comprised 30,542 foot, 21,300 horse, 2,445 artillery, and 2,149 officers. The navy consisted of 10 screw steamers, with 39 guns and 121 marines. In 1872 an appropriation of \$2,200,000 was made for increasing the naval force, and it was decided that one small ship of war and two iron-clads should be purchased. The merchant navy in 1869 comprised 255 vessels, of 58,200 tons, with 2,900 sailors. The ordinary receipts of the government in 1871 were \$11,788,500, and the ordinary expenditures \$12,542,493, showing a deficit of \$753,993. The deficit in 1869 was \$2,481,443; in 1870, \$2,464,484. The national debt, Jan. 1, 1871, was as follows:

HOME DEBT.	Capital.	Interest.	Sinking Fund, 1870
Debt at 3 per cent.	\$3,216,200	\$97,853	\$45,550
Debt at 8 per cent.	2,585,400	216,128	116,200
Railway loans at 6 per cent. .	2,985,000	185,700	110,000
Other debts, from 3 to 5 pr. ct.	7,945,149	885,144
Total.....	\$16,731,749	\$885,024	\$271,750
FOREIGN DEBT.			
Loan of 1842, at 3 per cent. . .	\$1,915,500	\$58,965	\$50,000
Loan of 1848, at 4 per cent. . .	6,455,000	294,300	85,000
Loan of 1866, at 7 per cent. . .	5,096,500	366,590	140,500
Loan of 1867, at 6 per cent. . .	9,363,000	575,280	225,000
Loan of 1870, at 5 per cent. . .	5,013,000	253,175	50,500
Total.....	\$27,843,000	\$1,548,310	\$551,000
Total national debt, Jan. 1, 1871.....	\$44,574,749	\$2,383,334	\$822,750

—Chili was among the earliest of the South American states to encourage the building of railways. At the close of the year 1871 there were 474 m. open for traffic, and 138 more nearly completed. The following shows those in operation: from Santiago to Curicó, 116 m.; Valparaiso to Santiago, 115; Caldera to San Antonio, 93; Ovalle to Tongoy, 42; Coquimbo to Las Cardas, 40; Pabellon to Chañarcillo, 26; Carrizal Alto to Carrizal Bajo, 25; Llaillai to San Felipe, 17; total in operation, 474 m. The following are in course of construction: From Taleahuano to Chillan, 112 m.; San Fernando to La Palmilla, 19; San Felipe to Santa Rosa de los Andes, 9; total in construction, 1872, 140 m. Chili intends to cooperate with the Argentine Republic in building a railway across

the Andes at an early day. The surveys show that the Planchon pass is the most feasible route. The length of the road by this line will be 1,023 m., and its cost is calculated at \$23,000,000 for the Argentine division and \$6,000,000 for the Chilean. The time required to build it is estimated at four years. New railways are projected also from Mejillones to the silver mines at Caracoles, 100 m.; from Huasco to Vallenar, and from La Serena to Elgin; and the Copiapó company are to extend their line to the Cordilleras. Lines of telegraph are in operation from Santiago to Valparaíso, and from Copiapó to the mining districts. In July, 1872, the Trans-Andine line, connecting Santiago and Buenos Ayres, was opened to the public. A number of other lines are in course of construction or projected. On May 13, 1868, the first steamer of a line direct to Europe, by way of the strait of Magellan, sailed from Valparaíso. This line has an annual subsidy from the government of \$60,000, to be increased to \$100,000 as soon as permanently established.—Prior to 1450, the present territory of Chili was inhabited by the ancestors of the Indian tribes now found there, who seem to have all descended from a common stock, and called themselves by the general title *Alapu-che*, people or children of the land. They were subdivided into a number of tribes, but all spoke a common language. In 1450 Yupanqui, the reigning inca of Peru, formed the project of extending his sway over the Chilean territory, and, having stationed himself with a powerful army in Atacama, despatched his lieutenant Chinchiruca, with 10,000 men, southward to subdue the *Alapu-che*. With that tact which characterized the policy of the incas, Chinchiruca sought to win rather than conquer these rude and warlike tribes; and such were his powers of persuasion that tribe after tribe yielded to the "children of the sun," and in six years the inhabitants of northern Chili, for 600 m. from the Atacama frontier, acknowledged fealty to the Peruvian monarch. But his sway received a check. Pushing further south, his officers and soldiers encountered on the further bank of the river Rapel a warlike tribe of the *Alapu-che*, known as the *Purumancians*, who returned a defiant answer to the summons and representations of the inca, refused all overtures for peace, and attacked the Peruvian troops; a desperate battle followed, lasting three days, in which both armies were too thoroughly shattered to renew the conflict. Upon hearing of the result of this battle, Yupanqui wisely resolved to forbear offensive warfare, and to maintain only what he already possessed. When, some 80 years later, the Spaniards had overthrown the empire of the incas, they found Chili owning a nominal allegiance to the Peruvian monarch, and resolved to subjugate that country also; and Diego Almagro, from the double motive of glory and gold, led an expedition across the desert of Atacama and the mountain passes

of the Andes. When he reached Copiapó a quarter of his Spanish troops and three eighths of his Indian allies had perished from cold, fatigue, and starvation. They were received by the people very kindly, and met no opposition till they reached the territory of the *Purumancians*, where, like their predecessors, they found a foe so brave that they were fain to pause and retrace their steps. Almagro and the remainder of his force returned slowly and sadly to Peru, and five years elapsed before another expedition to Chili was attempted. Pedro Valdivia, a prudent and able commander, was selected for this service, and so well did he arrange his plans that, though occasionally meeting with hostile bands of Indians, he penetrated without serious difficulty to the river Mapocho, and encamped upon the present site of Santiago. Finding the location pleasant and the adjacent country fertile, he here founded a city, to which he gave the name of the patron saint of Spain. Scarcely had he fortified himself in his new town before the Indians, availing themselves of his temporary absence, assailed it, and would have taken it but for the hasty return of the commander; but though balked of their intended prey, they returned again and again to the charge, till Valdivia was compelled to send for reinforcements from Peru. After the arrival of these he proceeded southward, and, though the *Purumancians* seem to have offered no effectual opposition to his progress, he found after crossing the Maule, which formed their southern boundary, a new foe, braver and fiercer than any he had hitherto encountered—the *Araucians*, now for the first time appearing on the page of history. So terrible and unexpected was their first attack, that it well nigh annihilated Valdivia's army, and compelled him to retreat to Santiago, and eventually to return to Peru for further reinforcements. He returned in 1550 with a large and well appointed force, and founded the city of Concepcion, on a site now known as Penco. Here the *Araucians* rallied their forces, and with 4,000 men under Aillavalu attacked the new city with a more determined valor than any Spanish general had before witnessed. It was not until the fall of their leader that they would yield an inch of ground. Conflict after conflict followed, and in 1559 Valdivia was captured by the Indians and put to death. They afterward destroyed Concepcion, resisted all attempts to rebuild it, and eventually marched upon Santiago and placed it in great peril, but were finally repulsed. Under the count Mendoza the Spanish forces, often reinforced, still persisted in their policy of conquest; but at length, when more than 100 years had been wasted in the effort to drive the Indians from the territory south of the Biobio, the Spaniards were compelled in 1665 to make a treaty of peace, and acknowledge the independence of these mountain tribes, and establish the limits of their territory. This peace lasted till 1723, when war broke out again,

and lasted with slight intermissions for 50 years. Under Spanish rule Chili formed a viceroyalty divided into 13 districts. By perverse misgovernment the resources of the country were undeveloped and the minds of the people alienated. In 1810 began the revolution which resulted in its independence. In July of that year Governor Carrasco was deposed and a junta formed with the secret design of severing the connection with the mother country. In April, 1811, the first blood was spilled. The Spanish authorities, becoming apprised of the intentions of the patriots, attempted to overawe them and their leaders. Royal troops drawn up in the great square of Santiago were attacked by the patriots and defeated with a considerable loss on both sides. In the same year Don Juan José Carrera was appointed by the junta supreme president of the congress and general-in-chief of the army. In all the skirmishes in the beginning of the contest the patriots were successful. In 1813 a powerful army under Gen. Paroja invaded Chili, and was twice defeated by Carrera; but the royalists receiving large reinforcements, the country was overrun and obliged to own once more the sovereignty of Spain. After three years of tyranny, the patriots raised an army in La Plata, and under the command of Gen. San Martín marched into Chili and defeated the royalists at Chacabuco, Feb. 12, 1817. An elective government was organized, of which Don Bernardo O'Higgins was made supreme dictator. Again the Spaniards rallied, and in a battle fought at Chancarayada defeated the patriots with heavy loss. The royalists, lulled into security by the result of this engagement, were attacked suddenly by the Chilenos in the plains of Maypu, April 5, 1818, and routed with great slaughter, not more than 500 escaping from the field. This secured the independence of Chili, and decided as well the fate of Buenos Ayres and Peru. The port of Valdivia was held by the Spaniards till 1820, when it capitulated. Gen. O'Higgins held the dictatorship till 1823, when he was obliged to resign in consequence of a popular tumult. A provisional triumvirate succeeded him for a few weeks, when Gen. Freire became dictator. In 1828 a constitution was adopted. In 1831 a convention was called for its revision, the result of which was the present constitution, promulgated May 25, 1833. Though less revolutionary than some of the South American states, Chili has passed through several attempted forcible changes of the government. The most formidable of them occurred in April and September, 1851. That of April was instigated and commanded by Col. Urriola, who lost his life in a severe battle between the insurgents and the government forces at Santiago. That of September was led by Gen. De la Cruz, the defeated candidate for the presidency at the preceding election. At one time it threatened to prove a revolution, as in nearly every conflict the insurgents were victorious; but at length

the money of the government effected what the valor of its armies could not, and after 4,000 soldiers had fallen in battle and the productive industry and commerce of the country had suffered immense injury, the revolt was quelled and an amnesty granted to the insurgents. Chili passed through this crisis in her history under the presidency of Don Manuel Montt, a man of great ability, who had been the minister and adviser of Gen. Bulnes, his predecessor in office. He restored peace and prosperity to the country, and it has since enjoyed internal tranquillity. President Montt was reelected in 1856. Under his administration a civil code was framed, tribunals of commerce were established, a discount and deposit bank founded in Valparaiso, and a bank to advance money on real estate opened Jan. 1, 1856. Treaties of commerce were concluded with France in 1852, and with Sardinia and the United States in 1856; a free-trade treaty with the Argentine Republic in 1856 (abrogated in 1868); and with Great Britain in 1856. Walker's invasion of Nicaragua led President Montt to conclude, in November, 1856, a political alliance with Ecuador and Peru, which was joined by Costa Rica. In 1861 José Joaquín Pérez was elected president, and was reelected in 1866. In 1862 the Araucanians gave the republic much trouble, under the lead of De Tonneins, a Frenchman, who claimed to be king of Araucania and Patagonia, under the title of Orélie Antoine I. He was captured during the year, and confined in prison, but was released in 1863. In 1864 Chili sympathized warmly with Peru in her struggle with Spain, and in the following year became herself involved, and her coast was blockaded by a Spanish fleet. Chili declared war, and a loan of \$20,000,000 was authorized. On Nov. 26 the Chilean steamer Esmeralda captured the Spanish gunboat Covadonga, with Admiral Pareja's correspondence on board. Two days after Admiral Pareja, dispirited by want of success, committed suicide, and was succeeded by Commodore Nuñez. On Jan. 14, 1866, a treaty, offensive and defensive, with Peru was proclaimed. An engagement between the allied fleets of Peru and Chili and a part of the Spanish fleet took place Feb. 7, 1866. The Spanish withdrew, but little damage was sustained by either side. On March 31 Admiral Nuñez bombarded Valparaiso, notwithstanding the earnest protest of all the foreign ministers and consuls. The firing began at 9 A. M. and lasted $3\frac{1}{2}$ hours, between 2,000 and 3,000 shot and shell being thrown into the city. No shot was returned from the town. The destruction was immense, most of the public and many private buildings being demolished. The loss was estimated at \$10,183,000, of which about nine tenths was sustained by foreign residents. In April following the fleet left the Chilean waters, and the war thenceforth was merely nominal. A treaty of armistice and indefinite truce, brought about by the mediation of the United

States, was signed at Washington April 11, 1871. In 1869-70 the Araucanians again proved troublesome; but in 1871 their self-styled king had left the country, and Chili was preparing to occupy it permanently. During the past few years Chili has made great material and intellectual progress. New mines have been opened, agriculture has made steady advances, means of communication have been increased, schools and libraries have been established, and improved means of education adopted, and numerous measures of social reform inaugurated. Agricultural schools have been founded, and a national agricultural society is in successful operation. In 1873 this society sent a collection of the agricultural products of the country to the Vienna exposition. Religious instruction is no longer made obligatory in private schools; dissenters from the established Roman Catholic religion are allowed to worship in buildings belonging to private individuals, and to be buried in the cemeteries; and civil marriages have been legalized. Among new measures proposed are a bill for the abolition of flogging, another for the reform of the election laws, and a third for a new assessment of landed property. A mole, to cost \$400,000, is to be constructed at Valparaiso; the navigation of the river Valdivia is to be improved; and the bar at the entrance of the Maule is to be opened, so as to render the harbor of Concepcion more accessible. There is also a project to widen the principal streets of Santiago, and to beautify it. There is a strong liberal party in Chili in favor of curbing the power of the clergy in political affairs, of separating church and state, and of abolishing the property qualification for suffrage. Suffrage is now much restricted, there being only about 40,000 voters in a population of 2,000,000. In the election of 1871 the liberals nominated as their candidate José Urmenita, and he was supported by a large portion of the wealth and intelligence of Chili; but Federigo Errazuriz, the candidate of the clerical party, was elected, all the government patronage being employed in his interest.—The following works treat of the history, geography, commerce, &c., of Chili: Molina's "History of the Conquest of Chili" (1782), and "Geographical, Natural, and Civil History of Chili" (1787; English translation, Middletown, Conn., 1808); M. Claude Gay's "Natural History of Chili," published by the government; Von Tschudi's "Peru;" Lieut. Gilliss's "Report of the United States Naval Astronomical Expedition" (6 vols., Washington, 1855-'8); and Lieut. Smith's "Araucanians" (New York, 1855). The subject of Ercilla's "Araucana," the greatest of Spanish epic poems, was a war with the Araucanians in the middle of the 16th century, in which the poet was personally engaged. (See EROILLA.)

CHILIASM. See MILLENNIUM.

CHILlicothe, a city of Ohio, capital of Ross county, on the right bank of the Scioto river, 45 m. in a direct line, or 70 m. following the

windings, above its junction with the Ohio, and 3 m. above the mouth of Paint creek, 45 m. S. of Columbus, and 96 m. N. E. of Cincinnati; pop. in 1870, 8,920. The Marietta and Cincinnati railroad renders accessible the rich coal and iron mines of southern Ohio. The Ohio and Erie canal extends from Portsmouth, at the mouth of the Scioto, through this city, to Columbus and Cleveland. Chillicothe is the centre of nearly all the trade of the rich farming country bordering on the Scioto, one of the finest agricultural districts of the United States. It is beautifully situated, 30 ft. above the river, on a plain which forms the bottom of a valley, enclosed by two ranges of cultivated hills 500 ft. high. The principal avenues follow the course of the stream, and are intersected at right angles by others, all lighted with gas, and regularly planned. The two main streets, which cross each other in the centre of the city, are each 99 ft. wide; Water street, facing the river, is 82½ ft. wide; and the width of the others is 66 ft. A supply of water is obtained from works erected at a cost of \$75,000. There are many handsome public buildings, including 13 churches, 4 brick school houses, and a stone court house, which cost over \$100,000. The manufacturing industry is important, embracing 7 carriage and wagon factories, 3 flour mills, 5 bakeries, a machine shop, a saw mill, a distillery, a manufactory of agricultural implements and edge tools, a planing mill, a paper mill, a pork-packing establishment, a book-bindery, an iron foundery, and a manufactory of mattresses. There are 11 hotels, an insurance company, and 3 national banks with an aggregate capital of \$400,000. The city is divided into four wards, and is governed by a mayor and a common council of two members from each ward. It contains 36 public schools, including a high school, which in 1871 had 42 teachers and an average attendance of 1,857. There are also two Catholic parochial schools, with an average attendance of 692, a commercial college, a select school for girls, and three newspapers. Chillicothe was founded by emigrants from Virginia in 1796, and from 1800 to 1810 was the seat of the state government.

CHILLIES. See CAPSICUM.

CHILLINGWORTH, William, an English divine and controversial writer, born at Oxford in October, 1602, died at Chichester, Jan. 30, 1644. He was admitted a scholar of Trinity college, Oxford, in 1618, and elected a fellow in 1628. He made great proficiency in divinity and mathematics, and displayed remarkable skill in disputation. The theologians and university scholars in his time were constantly debating the comparative merits of the churches of England and Rome, and Chillingworth, while delighting in ingenious argumentation, became unsettled in his opinions. A Jesuit named Fisher convinced him of the necessity of an infallible rule of faith, whereupon he immediately abjured Protestantism and proceeded to the college of the Jesuits at Douai. He had

no sooner taken this step than he "doubted that his new opinion was an error," and by invitation of Laud, then bishop of London, he returned to Oxford to reëxamine the whole question. He soon abandoned the Roman church, and in 1634 wrote a refutation of the arguments which had induced him to join it. Engaging in controversy with several distinguished Jesuits, he published in 1638, in answer to one of them, his "Religion of Protestants a Safe Way to Salvation," which passed to a second edition in five months, was received with general applause, and is still esteemed one of the ablest defences of the Protestant cause. Maintaining that the Protestant's sole judge is the Bible, and its sole interpreter private judgment, he was opposed not only by the Roman Catholics but by the Puritans, who affirmed that he destroyed faith by resolving it into reason. The appellations of Arian and Socinian were applied to him, and he for a time declined preferment on the ground of scruples in regard to subscribing to the thirty-nine articles. In 1638 he subscribed to the articles, regarding them as a basis of peace or union and not of belief or assent, and was promoted to the chancellorship of Salisbury, with the prebend of Brixworth annexed. During the civil war he was zealously attached to the royal party, and at the siege of Gloucester in 1643 he directed the making of some engines in imitation of the Roman *testudines* for assaulting the town. He was taken prisoner a few weeks before his death, and was buried in the cathedral of Chichester. Dr. Cheynell, who was one of his severest antagonists, attended and treated him kindly in his last sickness, but appeared at his funeral, and after an admonitory oration hurled a copy of the "Religion of Protestants" into the grave of its author, exclaiming, "Earth to earth, dust to dust." Cheynell published "*Chillingworthi Novissima*, or the Sickness, Heresy, Death, and Burial of William Chillingworth" (1644; 2d ed., 1725), which has been described as "the quintessence of railing, which ought to be kept as the pattern and standard of that sort of writing." The works of Chillingworth have been frequently republished, the earliest complete edition being that of London, 1742, in folio, with a life of the author by Dr. Birch (new ed., 3 vols. 8vo, Oxford, 1838). The constant study of them is recommended by Locke "for attaining the way of right reasoning." Anthony Wood affirms that "it was the current opinion of the university that he and Lucius, Lord Falkland, had such extraordinary clear reason that if the great Turk or the devil could be converted, they were able to do it." His character and ability were admired by his contemporaries, and he was reckoned the most acute logician of his age; yet Lord Clarendon says that he "had contracted such an irresolution and habit of doubting, that at last he was confident of nothing." He has therefore been cited by Dugald Stewart as an instance of the ruinous effects of scholastic logic.

CHILLON, Castle of, a fortress in the canton of Vaud, Switzerland, near the E. extremity of the lake of Geneva, on an isolated rock surrounded by deep water, and connected with the main-

Castle of Chillon.

land by a wooden bridge. It was built according to some historians in 1120, and according to others in 1236 or 1238. It is not certain by whom it was built, but it is attributed by some writers to Amadeus IV. of Savoy. For many years it was a state prison. Bonnivard, prior of St. Victor, was confined here from 1530 to 1536. The place has been rendered famous by Byron's "Prisoner of Chillon." The castle is now used as an arsenal.

CHILMARI, or **Chilmaree** (Hindoo, *Chalamari*), a beautifully situated but ill-built town of Bengal, on the Brahmapoetra, in the district and 36 m. S. E. of Rungpoor. At certain religious and commercial festivals, from 60,000 to 100,000 Hindoos are said to assemble here.

CHILO, or **Chilon**, one of the seven sages of Greece, and one of the ephori of Sparta, flourished about the commencement of the 6th century B. C., and is said to have died of joy on occasion of his son's gaining the prize for boxing at the Olympic games. The institution of the ephorality has been frequently, but it is believed erroneously, ascribed to this sage. According to Pliny, he caused the words "Know thyself" to be inscribed in letters of gold on the temple of Delphi. He said that three things were very difficult: to keep a secret, to make the best use of time, and to suffer injuries without murmuring.

CHILOE. I. The southernmost province of Chili, comprising the island of the same name and the other islands of the archipelago of Chiloe, and the islands of the archipelago of Chinos. Since 1865 the entire western coast of Patagonia, up to the ridge of the Cordilleras, and its islands as far as Cape Horn, have been added to it. Exclusive of this addition, over which the jurisdiction of Chili is merely

nominal, the area of the province is estimated at about 9,050 sq. m.; pop. in 1870, 62,983. The chief towns are San Carlos or Ancud, the capital, Castro, and Chacas, all on the island of Chiloe. **II.** An island in the above province, lying off the S. W. extremity of Chili, between lat. 41° 45' and 43° 30' S., and lon. 73° 30' and 74° 30' W. It is separated from the mainland on the N. by the strait of Chacas, about a mile wide, and on the E. by the gulf of Ancud, about 35 m. wide. It is 120 m. long from N. to S., and about 50 in breadth at the widest part; but a deep indentation reduces its breadth in the centre to about 15 m. The western coast is rocky, rising abruptly from the sea to a height of from 1,500 to 3,000 ft.; on the east the coast is of moderate elevation. There are numerous inlets which afford good anchorage, but no large harbors; the best are San Carlos, Castro, Chacas, and Dalcahue. The interior is little known, being filled with rugged mountains, some of which are sterile and some covered with dense forests. The climate is temperate and healthy, but is unpleasant on account of the incessant rains which prevail for ten months in the year. The air is almost continually loaded with moisture, so that it is frequently necessary to dry the wheat and barley crops by artificial means. Ice does not form, and frost and snow are rare. The soil is a rich sandy loam of extraordinary fertility, but, on account of the dampness of the atmosphere, the cereals do not thrive. The potato is indigenous, and has reached by cultivation a fair degree of excellence. Flax, tobacco, vegetables, and fruits are also raised. Agriculture is in a very primitive condition, the implements used being of the rudest description. Cattle, sheep, and swine are bred in great numbers. The horses are small, but hardy and strong. Poultry of all kinds abounds. Fish and shell fish are found in abundance along the coast, and constitute an important part of the food of the inhabitants. Traces of coal exist, and some of the streams are strongly impregnated with copper, iron, and other minerals, but no mines have been developed. The principal manufactures are *casso*, a coarse woollen cloth, dyed blue, used for men's garments, ponchos, blankets, and other fabrics of wool; cables, hawsers, and ropes are also made, and salt and dried fish are prepared to some extent. The chief exports are timber, fire wood, hides, wool, hams, dried fish, brooms, and a little wheat. The imports are sugar, wine, brandy, tea, salt, indigo, hardware, wearing apparel, and household furniture. The inhabitants are whites, Indians, and mixed. The whites are either Chilenos or Spaniards, the latter being almost the only Europeans. The Indians, who are Araucanians, are few in number. The people of all classes are temperate and honest, drunkenness and crime being nearly unknown. Chiloe was discovered by the Spaniards in 1558. Castro on the E. coast, founded in

1566, was formerly the capital.—The Chiloe archipelago is composed of the island of the name and of over 60 smaller islands, lying between it and the mainland, about half of which are inhabited. Several of them are well cultivated, but most are mountainous and sterile. The principal ones are Quinchas, Lemny, Chalbuco, and Llaicha.

CHILTERN HUNDREDS, a small hilly district extending through part of Buckinghamshire and Oxfordshire, England, to which a nominal office is attached in the gift of the crown, the person chosen to fill it being called the steward of the Chiltern Hundreds. This office is associated with a parliamentary usage of England. A member of the house of commons cannot directly resign his seat; to accomplish that object indirectly, it is customary for a member wishing to resign to accept a nominal office under the crown, such as the stewardship of the Chiltern Hundreds, whereby his seat in parliament is vacated, and a new writ is issued.

CHIMÆRA, in Grecian mythology, a three-headed, fire-breathing monster, sprung from Typhon and Echidna, and killed by Bellerophon.

Bellerophon on Pegasus attacking the Chimæra.

phon. The fore part of its body was that of a lion, the hind part that of a dragon, and the middle part that of a goat; while it had three heads, each of which resembled that of one of the three animals. It was described by the poets as committing great ravages in Caria and Lycia, and some critics suppose that the myth was suggested by the volcano called Chimæra near Phaselis in Lycia. Works of art have recently been discovered in Lycia on which the Chimæra is represented, not as a monster of triune conformation, but in the simple form of a species of lion still found in that region. The term *chimæra*, applied figuratively to a vain, idle fancy, is derived from this fabled monster.

CHIMÆRA, a name given to the holoccephalous suborder of the selacians or sharks, from their strange appearance. (See SEA CAT.)

CHIMAPHILA (Gr. *χειμα*, winter, and *φίλος*, a friend), a drug consisting of the leaves of *chimaphila umbellata*, a small evergreen plant called wintergreen or pipsissewa, belonging to the heath family, growing in the northern latitudes of both continents. The leaves contain a resin, a bitter principle, a volatile oil, and tannic acid, all of which contribute to its medicinal efficacy. It is used in affections of the kidneys and urinary passages, acting as a diuretic and astringent. Decoctions and extracts are employed. *C. maculata* probably possesses similar virtues. The dose of the decoction is a pint in 24 hours; of the fluid extract, half a dram to a dram.

CHIMARA, Khimara, or Chimari. See CERAUNIAN MOUNTAINS.

CHIMAY, the name of a little principality in the Belgian province of Hainaut, with a thriving capital of the same name on the river Blanche, in the arrondissement of Charleroi. In former times it belonged to the lords of Croy. In 1470 it was made a county by Charles the Bold of Burgundy, and in 1486 a principality by Maximilian of Hapsburg. After passing through various hands, it came by inheritance in the beginning of this century to the French family Riquet de Caraman.

CHIMAY, Jeanne Marie Ignace Thérèse, princess of, born in Saragossa about 1775, died in Belgium, Jan. 15, 1835. She was the daughter of Count Cabarrus, minister of finance in Spain. Married at a very early age to M. de Fontenay, a councillor to the parliament of Bordeaux, from whom she was soon divorced, she became interested in the revolutionary movement, but gave umbrage to the government and was arrested. Tallien, on passing through Bordeaux, fell in love with her, procured her liberation, and finally married her. On her arrival in Paris, her beauty created a great sensation. She took a deep interest in politics, siding with the moderate republicans. She prevailed upon her husband to engage in a plot for the overthrow of Robespierre, and was thus the promoter of the revolution of Thermidor (July, 1794). From this period her house became the centre of the most brilliant society of Paris, and she was for years, but especially during the directory, the queen of fashion. She appeared in the Tuileries in a Greek or Roman costume, remarkable for its transparency, and won admiration by the classical perfection of her person. Such triumphs were far from being agreeable to her husband, who had still more serious causes of complaint. He left France, first travelling in England, then accompanying Bonaparte to Egypt. On his return to Paris he was divorced from his wife by mutual consent. In 1805 she took as her third husband Count Caraman, François Joseph Philippe de Riquet (born Sept. 21, 1773, died March 2, 1843), who soon became prince of Chimay, and lived with him on good terms, residing in Paris, Nice, or at his castle of Chimay in Belgium. She kept for many years her rank among the

beauties of France, but was never admitted to the court of Napoleon; and although her husband had access to nearly all the courts of Europe, she was excluded from them, even from that of Belgium, where the prince held the office of first chamberlain to Leopold. Her revolutionary reputation had closed to her the doors of the monarchical world. She was not only a handsome, but a most generous, kind, amiable, and witty woman, always ready to serve even her enemies. A lady whom she had saved from death during the revolution said of her, "If you call Madame Bonaparte our lady of victory, you must call Madame Tallien our lady of good help."

CHIMBORAZO, a mountain of Ecuador, South America, the most famous peak of the Andes, situated in lat. 1° 30' S., lon. 79° W. It was

Chimborazo.

for a long time supposed to be not only the highest point on the western continent, but the highest in the world. This distinction it has now lost, as it ranks only as the sixth among the loftiest peaks of the Andes, and falls far below some of the mountains in the Himalaya chain. Its elevation above the sea was ascertained by Humboldt to be 21,422 ft. It is surrounded by high table lands, above which it rises less than 12,000 ft., so that on a near approach it appears less gigantic than when viewed from a distance. The form of the mountain is that of a truncated cone, and its appearance from the coast of the Pacific is peculiarly grand. Nearly 200 m. distant, it

resembles an enormous semi-transparent dome, defined by the deep azure of the sky; dim, yet too decided in outline to be mistaken for a cloud. Its top is covered with perpetual snow. Humboldt and his companions, in June, 1802, made extraordinary exertions to reach its summit, and arrived within about 2,000 ft. of that point, then believed to be the greatest elevation ever attained by man. Here they planted their instruments upon a narrow ledge of porphyritic rock, which projected from the vast field of unfathomed snow. A broad impassable chasm prevented their further advance; besides which, they felt in the extreme all the usual inconveniences of such high situations. They were enveloped in thick fogs, and in an atmosphere of the most piercing cold. They breathed with difficulty, and blood burst from their eyes and lips. J. B. Bous-singault, in December, 1831, ascended still higher, reaching an elevation of 19,695 ft.; but the summit of this gigantic mountain still remains unexplored by man.

CHIMES, a set of bells tuned to the modern musical scale, and struck by hammers which are moved either by clockwork or by hand. In the latter case they are commonly termed *carillons*, a name applied by the French in common parlance indiscriminately to the tune played and to the series of bells, whether sounded by machinery or by hand, though the most accurate writers distinguish the latter as *carillons à clavier*. The mechanism for sounding chimes consists of a cylinder from the circumference of which project pegs placed at proper intervals according to the order in which each bell is to be struck. This is made to revolve by clockwork, and the pegs are thus brought into contact with levers operating upon the bell hammers. Carillons are played by means of an attachment similar to the key board of a pianoforte; for the larger kinds the keys are of great size, and the performer strikes them not with his fingers but with his fists, which are guarded by leathern coverings. Notwithstanding the great force requisite in playing this colossal instrument, musicians have sometimes acquired marvellous skill in performing on it the most difficult airs. It is often adapted to music in three parts, the base being played on pedals and the first and second trebles with the hands. Potthoff, a blind organist and carillon player of Amsterdam, used to execute fugues on it, though every key required a force equal to the weight of 2 lbs. A pleasing application of chimes is made to clocks and watches, by which they ring out the hours, halves, and quarters. When intended to be placed in a small compass, the bells are arranged concentrically one within another. This species of music is supposed to have originated in some of the monastic institutions of Germany, and the first instrument for producing it is said to have been made at Alost, in the Netherlands, in 1487. Among the finest sets of chimes in Europe are those at Copen-

hagen and Ghent. At Amsterdam there are both carillons and chimes, the former of three octaves, with all the semitones complete.

CHIMNEY (Lat. *caminus*, Gr. *καμινος*, a furnace), the flue for producing a draught and conveying off the smoke of a fire. Simple as these contrivances are, chimneys do not appear to have been known in ancient times. According to Tomlinson, they were probably in use in England before those of Padua, the earliest record of which carries them back to some period previous to 1368, when Carraro, lord of Padua, introduced them into Rome. But the use of the curfew bell in preceding centuries indicates their absence, when the practice prevailed of thus summoning the people to cover over the fires that burned in pits in the centre of the floor, under an opening in the roof. In Venice they appear to have been common in the 14th century, a number being thrown down, it is recorded, by an earthquake on Jan. 25, 1347. Leland thus speaks of Bolton castle, which he says "was finished or kynged Richard the 2 dyed:" "One thyng I muche notyd in the hawle of Bolton, how chimeneys were conveyed by tunnells made on the syds of the walls betwyxt the lights in the hawle, and by this means, and by no covers, is the smoke of the harthe in the hawle wonder strangely conveyed." But for centuries afterward they appear to have been known only as luxuries in the houses of the great; and in the time of Queen Elizabeth visitors were occasionally sent to houses thus provided, that they might have the enjoyment of this convenience. Beckmann, in his "History of Inventions," has gathered from ancient sources many curious allusions to what in our translations are called chimneys; but these appear after all to have been nothing better than holes in the roof, through which the smoke found its way out, as from the wigwags of the American Indians. Neither Vitruvius nor Julius Pollux, an ancient lexicographer, who gives the names of all parts of a house in Greek, nor Grapaldi, who does the same in Latin, makes mention of chimneys. Among the most ancient ruins no traces of them are found, nor have any been discovered in Herculaneum, though charcoal has been met with in some of the apartments. The mode of warming rooms appears to have been to place upon the floor a portable pan or furnace containing live coals. Hence the propriety of the observation of the poet Sosipater, that one qualification of a perfect cook was the art of determining which way the wind blows; and also of the advice of Vitruvius, that there should be only plain cornices in rooms where there are to be fires and lights, as more elaborate ornaments would soon be filled with soot. Anacharsis, the Scythian, speaks of the Greeks keeping the smoke without, and bringing only fire into their houses; and Heliogabalus is said by Lampridius to have burned in the stoves spices and costly perfumes instead of wood. The Persians, who still retain some of the most

ancient customs, are described by Pietro della Velle as making their fires in a round or square hole in the earth floor of their apartments, in which is an iron vessel containing the fuel. Over it is placed a low table, covered with a thick quilted cloth, reaching to the floor. The heat is described as being exceedingly agreeable, and not causing uneasiness to the head, though no provision is made for conveying away the gaseous products of combustion. A pipe for blowing the fire with the mouth is made to project up from the floor.—To such expedients were the most refined nations of antiquity probably reduced in their ignorance of the simple chimney flue; a fact which would seem quite irreconcilable with the progress they had made in many of the arts dependent more or less upon the use of fires, were it not that these were less essential to them than to the inhabitants of more northern latitudes. The tendency of heated air to ascend must have been almost as familiar to them as that of water to flow down inclined planes; and to us it would seem to require not much more ingenuity to devise pipes for conveying the former away, than to contrive aqueducts which to this day are regarded as extraordinary works of art. It was the every-day need of supplies of pure water, and not of artificial warmth, which alone made the difference. This tendency of warm air to form ascending currents comes from its greater proportional lightness as it is expanded by heat and made to occupy a greater space. Deep mines in cold countries well exemplify the working of this principle. In the winter season the deep shafts are perfect chimneys of ventilation. The air enters the mines through the lowest openings into them, and mixing with the smoke of the candles and of the gunpowder blasts, acquires from these, and from the warmer underground temperature, a greater heat than that of the air above. Expanding in bulk, it floats upward, establishing an ascending current, which is renewed by succeeding portions of air, and which rapidly sweeps off the gaseous impurities of the mine. But as the weather becomes warm, and the air within and without attains the same temperature, no such current is formed, and the smoke, settling in a cloud below, slowly finds its way out by those passages through which at other times the fresh air is wont to flow in. Artificial means of ventilation then become necessary. Fires are built in the mine or at the mouth of the shaft, and the foul air is also forced out by blowing machines. The ascensional power of a column of heated air is the difference between its weight and that of an outside column of the same height. It is hence increased by adding to the height of the chimney, as well as by increasing the temperature. But the chimney may be so high, especially when exposed in cold situations, that the heat taken up below may be dispersed before the air reaches the top. In this case increased height adds nothing to the draught, but di-

minishes it. Short chimneys may be made more effectual by increasing the temperature, and in locomotives this is done by the introduction of a jet of hot steam. Calculations have been made to estimate the ascending force of air in chimneys at any given increase of temperature over the external air; but these are affected by many sources of error, which render the results only approximate. The flow of air over rough surfaces is retarded by increased friction, and in small flues it experiences this resistance more than in large ones of the same construction, in the inverse proportion of the diameters of the flues. In order to apply these calculations, it is necessary to know the mean temperature of the column of air in a chimney, and this cannot be determined with accuracy. It may be approximated by finding the degree of heat a little above the lower entrance into the flue, and that at the top, and taking half of their sum. Montgolfier, the inventor of balloons, first gave attention to this subject, and proposed the following method of determining the force of the draught, or the velocity of the current, which is still considered as simple and accurate as the case admits of. It is the same velocity which a falling body would acquire in passing the distance equal to the difference in height between two equal columns of air at the different temperatures. As the velocity of a heavy falling body is ascertained at any period of its descent by multiplying the square root of the number of feet it has fallen by 8, which gives its rate per second of time, we have the data for applying to the calculations for determining the velocity of the current. Suppose the height of the chimney to be 70 ft., and the difference of temperature of the two columns to be 30°, we have the expansion of the heated column = $70 \times .0661$ (this decimal representing one sixth of the expansion due to a difference of 180° of temperature). The difference in the height of the two columns is then 4.627 ft., and the square root of this (2.15), being multiplied by 8, gives 17.2 ft. per second as the velocity of the draught. For the further consideration of chimneys especially intended to feed fires with a draught of air, see FURNACE.—Smoky chimneys have a variety of causes, such as imperfections in the flue, too contracted dimensions, too rough an inner surface, openings which admit cold air and chill it, and, the most common of all, too large an opening at the fireplace or throat. Count Rumford paid much attention to the cure of smoking chimneys. He generally found the cause to be too large a throat, and his usual remedy was to diminish it by building a bench of brick in the back of the fireplace, reaching up to the throat, and to lower the fireplace somewhat. Sometimes the aperture at the top is too large, particularly if it is below the level of some neighboring house, hill, or high trees, from which the wind may be reflected down into the chimney, or over which it may fall, and thus beat down the

smoke. An inadequate admission of air into the room in which is the fireplace will cause a chimney to smoke, a circulating current being thus as effectually prevented as if the flue itself were in great part obstructed. The opening of a door or window often shows the cause of this trouble by at once removing it. When two chimney flues come down into one room, or into two rooms which connect by an open passage, the burning of a fire in one flue may establish an upward current, which is supplied with air drawn down the other. Any attempts to make the second chimney draw could only succeed by closing the connection between them, or supplying the first with the air it requires from some other source. When a chimney smokes in consequence of the wind beating down, the height may be increased, or the diameter at the top contracted; but the most efficient remedy is usually found by adjusting a bent tube to the top of the chimney, and keeping its mouth turned in the direction of the current of air by means of a vane. The effect of the latter change is to admit a smaller quantity of air, and this is dispersed through the large body in the flue without being felt at the base. The worst chimneys usually draw well when a stove is substituted for the fireplace, and the pipe is led into the chimney. This causes an increased current in the smaller channel, being equivalent to contracting the throat of the chimney when the fireplace is used.—Tall chimneys are built to convey away the noxious fumes from chemical and manufacturing establishments, and relieve the neighborhood of the nuisance these would otherwise occasion. They are built up from a solid base, with side flues leading into the central cavity. The size of this cavity should, as in the chimneys of dwelling houses, be of rather larger area than the sum of that of the flues which lead into it. In large stacks it varies from 3 to 6 ft. in diameter. They are constructed with a brick lining, so laid as to leave an air space between it and the outer wall, the effect of this being to check the rapid dispersion of the warmth of the vapors. A chimney of this kind has been erected at Manchester, England, 415 ft. high, 25 ft. square at the base, and 9 ft. at the top. It required to build it 4,000,000 bricks. At the Thomas iron works, on the Lehigh river in Pennsylvania, are cylindrical chimneys of a thin boiler-plate iron casing, lined with fire brick; the casing being 7 ft. in diameter, and the fire brick a foot long, made and bevelled to fit the circle, the internal diameter is 5 ft. These chimneys, for their capacity, are light, substantial, and elegant; but they are not built with reference to retaining the heat of the vapors, which is here no object.

CHIMPANZEE (*troglydytes niger*, Geoff.), the form of the four-handed animals which comes the nearest to man; so much so, indeed, that Linnæus places it under the genus *homo*, with the epithet *troglydytes* to distinguish it from man. It differs from the orang outang in

having the cranium broader in proportion to the face; in the characteristics of the skull; in the smaller size of the incisor and canine teeth, and inferior development of the jaws, giving it a more human and less beast-like head; in the difference of size in the vertebrae, the cervical being smaller and the lumbar larger in the chimpanzee; in the possession of additional dorsal vertebrae, corresponding to a second pair of ribs; in the comparative shortness of the forearm and hand; in the greater proportional length of the femur and tibia, and the less proportional length of the foot; and in many other points in the structure of the chest, loins, hands, nails, and fingers, extending in all to 23 points of difference in the osteological structure of the animals; of these 23 points, 20 in the chimpanzee have a greater similarity than in the orang to the same points in the human being, and three in the orang have a greater similarity to those of man than the

Chimpanzee (*Troglodytes niger*). 1. Hand of Chimpanzee. 2. Foot. 3. Skull.

same in the chimpanzee. Owen well observes that from these considerations, and especially from the conformation of the jaws and dental system, which in the orang are scarcely inferior to those of the lion, and greatly resemble those of the fiercer and more terrible carnivora, the chimpanzee ought to rank above the orang. The importance of these distinctions is not easily understood or appreciated from the reading of even the most lucid description, while it is seen in a moment by a glance at the skeletons of the animals, or at drawings of them. The chimpanzee is a native of Africa only, and is found principally on the Congo and Guinea coasts, and in Gaboon. The length of the arms is very great, reaching below the knees by the whole extent of the fingers. The legs have a sort of calf, but it differs from that of the human being in that it continues of equal thickness nearly to the heel. The hand differs from that of man in having the thumb much the smallest of the

fingers; the foot is properly a hand, appended to the tarsus, with a thumb extremely long, powerful, and capable of great extension. The chimpanzee walks more frequently erect on its feet than the other species, but stands with the feet much wider apart than man, and goes with the knees much more bent; and it cannot long maintain the erect position without support. It is a hideous caricature of the human race when alive; its structural differences not being nearly so distinguishable when the skeleton is clothed with the muscular flesh and covered with the hairy skin, as when it is seen denuded. It is 4 to 5 ft. high when erect, and is covered with black hair; the food is entirely vegetable; its strength is very great. In captivity in cold climates, it usually soon dies of consumption. The habits of the adult chimpanzee are very imperfectly known; what is collected concerning them being little more than the reports of the negroes, who, always addicted to the marvellous, are further possessed by a dread of these animals, at once physical and superstitious. Whenever they succeed in killing one of them they make a fetish of the cranium. Cuvier states that "the chimpanzees live in troops, construct themselves huts of leaves, arm themselves with sticks and stones, and employ these weapons to drive man and the elephant from their dwellings." He also repeats the story of their pursuit of the negroes, and carrying them off into the woods, which is still credited in the country where they are found. No reliance whatever is to be placed on the accounts of the gentleness, docility, and aptitude at acquiring human habits, of these animals when in captivity. Such anecdotes always relate to animals taken extremely young, and rendered timid and docile by the handling of the sailors, who make pets of them. As they become old they become sullen, savage, and ferocious; and there is reason to believe that there is no animal more brutally and irreclaimably vicious than one of the old males of any of these large anthropomorphous apes, whether they be oranges, gibbons, chimpanzees, or gorillas. (See *QUADRUMANA*.)

CHIMSEYANS, a nation of Indians on the northwest coast of America, extending from Milbank sound to Observatory inlet (lat. 53° to 55° N.), and including the Sebassas, Neece-lowes, Nass, and other offsets. Their language is bold, sonorous, and emphatic. They are noted for the process of inserting a piece of hard wood or ivory in a slit in the lower lip. The Chimseyans communicate with the northern branches of the Tacully or Chippewyans.

CHINA (Chinese, *Tsin*, or *Tui-tsing*). **I.** An immense empire of eastern Asia, comprising the eighteen provinces or China proper, Mantchooria, Inner and Outer Mongolia, Ili or Chinese Turkistan, Koko-nor, and Thibet. Corea and the Loochoo islands are nominal dependencies. It is bounded N. and N. E. by Asiatic Russia, whose territory on the Pacific recently acquired from China touches the Korean fron-

tier, E. and S. E. by Corea and the Yellow and China seas, S. by the gulf of Tonquin, Anam, Siam, and Burmah, and S. W. and W. by India and the states of Independent Tartary. Since the cession to Russia in 1858 of a region comprising about 300,000 sq. m., the most northern point of the empire is the northern bend of the Amoor river, lat. 53° N., and the eastern limit is the junction of the Usuri and Amoor rivers in lon. 136° E. The bay of Galong in Hainan, the southernmost point, is in about lat. 18° N., and Kara-tag, the westernmost, is in lon. 72° E. The area, deducting the territory ceded to Russia and estimated above, is 5,000,000 sq. m. according to McCulloch, 5,126,000 according to Balbi, or 5,559,564 according to Berghaus, about a third part of the continent, and a tenth of the habitable globe. Next to Russia it is the largest state which has ever existed. The integrity of the empire has however been greatly threatened during recent years. Mohammedan insurgents are in possession of portions of the provinces of Yunnan, Shensi, and Kansuh, and an independent government appears to exist in Chinese Turkistan, holding sway as far as Barkul. China is carrying on military operations in these several districts, and her former territory is likely to be reoccupied; but Russia may forestall her in some portion of it. (See *MANCHOORIA*, *MONGOLIA*, &c.) **II. China Proper** is by its inhabitants called Chungkwoh (middle kingdom), or Chung-hwa (central flowery land); by the Russians and the inhabitants of northern Asia, Kitai, Ketan, or Katai (whence the ancient name Cathay); by the Anamese, Sina; by the Persians, Chin; by the Thibetans, Yulbu. It extends from lon. 98° to 123° E., and from lat. 18° to 43° N., and is bounded N. E. and N. by Mantchooria and Mongolia, from which it is separated by the great wall; E. by the ocean; S. by the gulf of Tonquin, Anam, Siam, and Burmah; W. by Thibet and Chinese Tartary. Its area is estimated by Sir George Staunton at 1,500,000 sq. m., inclusive of the province of Liautung, which lies beyond the great wall, and 1,297,999 sq. m. exclusive of it; by McCulloch at 1,348,870 sq. m.; by Malte-Brun at 1,482,091; and by Williams at 2,000,000, if the full area of the provinces of Kansuh and Chihli is included. Thus China proper is about seven times the size of France, or nearly half as large as all Europe.—The coast line from Hainan to Corea is about 1,750 m. long. From Hainan to the mouth of the Yangtse, especially in the south, it is bold and rocky, and abounds with islands, headlands, and inlets. From the Yangtse N. to the Shantung promontory it is low, and after passing the promontory again low-until the highlands E. of the gulf of Liautung are met. The southern coast has a barren uninviting appearance, but the islands of the Chusan archipelago are covered with verdure and exceedingly beautiful. The Shantung promontory again is uninviting. Near the Korean boundary great for-

ests line the shores. The waters of the Yangtse and Yellow rivers are charged with earth and give a distinct muddy color to the sea for many miles from the land, for the whole distance from the Chusan archipelago to the Shantung promontory, and to a considerable part of the gulf of Pechili. The numerous headlands, islands, and inlets of the S. E. coast afford many places of refuge for shipping, and the harbors of Hong Kong and Amoy are especially commodious and safe. Swatow, Foochow, Ningpo, and Shanghai cannot be considered first-class harbors. Each is situated upon a navigable stream, but the approaches are difficult and the depth of water is insufficient. There are several fine harbors on the coast of Shantung, of which Che-foo is the best known. Tientsin, the port of Peking, is 50 m. from the sea, and can be reached by vessels of not more than 1,000 tons burden. The harbor of Newchwang is similarly defective, but Talienswan bay offers an excellent harbor for Mantchooria. The access to this port from the land side is difficult, but it could be easily reached by a railway. The shores of Formosa and Hainan are rugged, and the ports are very inferior. Tientsin and Newchwang are closed by ice three months in the year.—The extent of China is so great and its topography so varied that it would be difficult to describe its surface as a whole. The following divisions are natural ones, and will assist to give a clearer view of the physical features of the empire than would be readily obtained by a study of its several arbitrary political divisions. 1. The mountainous region of the southeast is a district 1,000 m. long and 400 m. broad. It includes the southern and eastern portions of Kwangsi and Hunan, the whole of Kwangtung, Fokien, Chekiang, and Kiangsi, and the southernmost parts of Nganhwui. The highlands touch the coast everywhere south of Hangchow bay, and in the north occasionally reach the line of the Yangtse between the Tungting lake and Chinkiang. Throughout this area of more than 300,000 sq. m. there is no table land, no extensive plain, and no mountain chain conspicuous by reason of altitude or continuity. The mountains have a trend which corresponds with the general direction of the coast. The ranges are short and irregular, and permit the streams which drain successive depressions to break through and to reach the coast without spreading into lakes. These hundreds of streams are the highways of this part of China. No one of them, excepting the West river, which debouches near Canton, is fit for steam navigation for any great distance. In nearly all, even near the coast, exist dangerous rocks and shallows which render necessary the transshipment of produce and merchandise in transit. But the Chinese, with characteristic patience and a lack of public spirit apparently equally characteristic, continue to use these streams, making no efforts to improve them. They are the only traffic

courses, excepting a few portages, such as those through the Chiting pass between Kwangtung and Hunan; the Mei-ling, between Kwangtung and Kiangsi; and the foot paths along which coolies carry burdens. 2. In striking contrast to this broken region is the level district which stretches away from the Hangchow bay to the mountains of Liautung. This district, known as the great plain, has for its northern boundary, beginning at the gulf of Liautung in lat. 40°, the great wall, the inner course of which it follows in a curving line to about lon. 114°. Its western boundary strikes thence due S. to the Yellow river, thence S. E. to the Yangtse near Nganking, and thence E. to Hangchow, which it reaches in lat. 30° 30'. The mountainous part of the Shantung province cuts down into the centre of the plain, and detached mountains near Nanking and Chinkiang break in upon it to a limited extent. 3. West of the great plain is a second broken region, which may be styled the mineral region of China. It lies south of Inner Mongolia, and comprises the provinces of Shansi and Shensi, the N. part of Hunan, and the E. of Kansuh. 4. South of the mineral region is the lake district or central China. It embraces the whole of the province of Hupeh, the S. W. part of Honan, and the N. of Hunan. It is crossed by the Yangtse, and its northern part is drained by the Han and its affluents. Lakes form so prominent a feature of this region that the name Hu-kwang, meaning broad lakes, is applied by the Chinese to the provinces of Hunan and Hupeh. 5. Szechuen is a province of such extent, population, and wealth that it may be considered a fifth natural division of the empire. It is a great inland district, bounded by mountains, but in the main made up of plains and gently undulating lands. Its population was set down in 1812 at 27,000,000, and as it has escaped the devastations of civil war it is probably much greater now. It is supplied by its own productions with the necessaries and even the luxuries demanded by the population. Its articles of export are of a nature to admit of easy transportation. Few regions of the earth are so favored as this. 6. The southwestern provinces are Yunnan and Kweichow. They are generally rough and mountainous, but in Yunnan there are some extensive table lands and some low-lying plains marked by lakes. This region is far more tropical in the nature of its climate and productions than the district east of it. The Chinese consider it unhealthy. They have done less here than elsewhere in China proper to subject the soil to tillage, and in consequence of this fact, and of the disturbed condition of the region owing to the Mohammedan and other troubles, it is now in great part an abandoned jungle.—The mountains of China hem in her territory on the north. In the east they separate the great plain from the elevated lands of Mantchooria and Mongolia. Further west taking the direction from N. E. to

S. W. which characterizes the mountains of the southern region, they bear down to the southern bend of the Yellow river. Two great ranges, the continuations of the Kuenlun and Himalaya mountains, extend from W. to E. nearly across the empire in the middle and south. The northern range enters China in about lat. 34°, and is generally termed the Peling. The southern crosses the empire in about lat. 25°, and is styled the Nan-ling. It is however the S. W. and N. E. ranges which chiefly determine the conformation of the surface of China, just as the Appalachians determine that of the eastern part of North America. These ranges are diversely named in different localities.—The most notable plain in China is the one already mentioned, which partly surrounds the mountains of Shantung, and is generally termed the great plain. It extends 600 m. from Peking in the north to Hangchow in the south, and has a breadth varying from 150 to 300 m. Its southern portion is the common delta plain of the Yangtse and Yellow rivers, the northeastern that of the Pei-ho. It is crossed by these three rivers, and suffers from the floods which they bring down, notably those of the Yellow river. That portion of the plain which lies south of the Yangtse has innumerable canals, and is protected along the Yangtse and other streams and the seashore by strong dikes and sea walls. In many places the surface has been raised so as to become fit for cultivation, by the excavation of canals and ponds. The Ta lake on its southern border appears not to have received the deposits of alluvial matter from the Yangtse which have rescued the neighboring plain from the waters of the ocean. That part of it which lies near the several courses which the Yellow river has pursued in different eras has been so frequently devastated by its floods that the great stream has been called China's sorrow. In the northern portion the climate is dry, and the soil does not produce more than a fraction of the yield procured further south. The years 1871-'2 were signalized in this region by very destructive floods, which covered a vast tract of territory between Peking and the gulf and further south. The people, having suffered for several generations in consequence of a too great diminution in the rainfall, are now driven from their homes by an excess of water. The next region of level country worthy of remark is that of central China. The general features of this district are the same as those of the great plain south of the Yangtse, and it is in these two districts that the system of canals is most extensive and perfect. The plains of Szechuen are higher, and may be compared with the rolling prairies of Iowa. The level portions of Kweichow and Yunnan are like the table lands of Mexico, but far less extensive, excepting the few alluvial districts which lie along the Yangtse and the Songtai or river of

Tonquin. The country near the West, North, and East rivers and the seacoast, in Kwangtung, is one of the most fertile portions of the empire. A great deal of level alluvial land is found here, and as the population is dense and industrious, the natural resources of the soil are improved to the utmost. In the northern part of Kiangsi lies the Poyang lake, which is surrounded by an extensive valley. Upon the streams running into the lake are found several large cities and innumerable towns and villages. The basin of the Wei-ho in Shensi comprises an area of about 60,000 sq. m. It is one of the most populous and fertile in the empire. The valley of the Fan in Shensi is less extensive, but equally rich and populous.—The rivers of China are worthy of the extent of the empire. Of these the Yangtse and the Hoang or Yellow are the chief, and rank among the leading ones of the globe. "These two great streams, similar both in rise and destination, descend with rapidity from the great table lands of central Asia, and each of them meets a branch of mountains which forces it to describe an immense circuit, the Hoang to the north and the Yangtse to the south. Separated by an interval of 1,100 m., the one seems inclined to direct itself to the tropical seas, while the other wanders off among the icy deserts of Mongolia. Suddenly recalled, as if by a recollection of their early brotherhood, they approach one another like the Euphrates and Tigris in ancient Mesopotamia; where, being almost conjoined by lakes and canals, they terminate within a mutual distance of 110 m. their majestic and immense courses." (Malte-Brun.) The Yangtse where it traverses the great plain is a broad, evenly flowing stream, admirably fit for navigation either by large or small steam or sail vessels. Beyond the plain it enters a broken country, then the low region of central China, beyond which steamers have penetrated to the foot of the gorges near Ichang in lon. 111° 30', 1,300 m. from the sea. The rapids and shallows of these gorges offer a bar to steam navigation, which Blakiston and the French exploring expedition of 1868 say might be overcome by the use of towing appliances from the shore. The rapids occupy a distance of about 40 m. Above them the river is continuously navigable for junks of 100 tons as far as Souchow in the province of Szechuen, a distance of 300 m. This great river does not compare in the extent of its navigable course with the Mississippi or the Missouri. The Yellow river is usually represented upon our maps as debouching south of the promontory of Shantung. It now pours its waters into the gulf of Pechili, having lately changed its course and taken a channel which is marked on the maps as that of the Tatsing river. Taking its rise at a point due west from its recent mouth upon the Yellow sea, and not more than 1,250 m. distant, it flows in alternating courses N., E., S., then E. again, traversing a distance of 2,000

m. before it finally breaks out of the elevated and broken lands which make its waters everywhere in its upper course turbulent and unsafe for navigation. Down through the alternating table lands and gorges of this tract it pours floods which are charged with a peculiar brownish yellow loam called by Mr. Pumpelly terrace deposit, and by Baron Richthofen *loess*. In its original state it is of such constitution that when a stream of water cuts down into it vertical banks are left. Throughout the districts where it is found the inhabitants make houses in the cliffs, whole villages being constructed in this way completely out of sight of the traveller upon the plains above. When a river washes the foot of a wall of loess, the earth softens at the water's edge, and after a time a cleanly cut section of the superincumbent mass drops into the flood, to be carried along until first the sandy and then the finer particles are deposited upon the plains below. A more slowly moving stream would be less charged with the loess, and would deposit it more rapidly. But the Yellow river can only carry the mass to the level country and then struggle with the shallows and banks which it forms. The result is that the river is almost useless for navigation, and its floods, which are numerous, become peculiarly dangerous to the lower country. At low tide there is about four feet of water on the bar at the mouth of the river, and there is no part of its course where steam vessels, excepting those of very light draft and small burden, could be used. It is believed that the floods of 1871-'2, which were disastrous to an immense region in eastern Chihli, came from the Yellow river. The area of its basin is estimated at 200,000 sq. m.; that of the Yangtse at 750,000. The Chu-kiang or Pearl river with its branches, the chief of which are called the North, East, and West rivers, drains the eastern part of the basin south of the Nanling. The West river is the largest of these branches, and will prove an important artery for steam navigation. The Chu-kiang and branches drain a region of not much less than 200,000 sq. m. The navigable course of the Pei-ho lies entirely within the great plain. Tientsin is the head of steam navigation. By a northern affluent large junks go nearly to the walls of Peking. Another affluent affords communication with the country south of Peking, and still another trends away nearly to the southern bend of the Yellow river. The flood of the Pei-ho is small in comparison with that of the Chu-kiang, but it drains a region of at least equal magnitude. The river Tonquin affords ready access to the southern part of the province of Yunnan, and was considered by De Carné to be a natural outlet for the produce of that region. The Min river, which flows by Foochow-foo, the Tsih, upon which Ningpo lies, and the Tsientang, leading up to Hangchow, are the most considerable among the lesser outlets. The Lian-ho and Yahyuen-kiang are the only ones deserving

mention in Shingking or southern Mantchooria. The Irrawaddy, Salwen, Menam, and Mekong draw a portion of their waters from the S. W. of China. The Songari has its source in Shingking.—The principal lake in China is the Tungting in Hunan, which is about 220 m. in circumference. It receives the waters of several small rivers, and discharges into the Yangtse by a short outlet at the north. There are many smaller lakes connecting with it. This is the system of lakes which has been noticed as a salient feature of central China. Their immediate basin is 200 m. long and 80 broad. The Poyang, 90 m. long and 20 broad, lies midway between the Tungting and the sea, and also discharges into the Yangtse. It is very shallow excepting in seasons of high water. The scenery of the country around the lakes is very beautiful. The Tahu, near the mouth of the Yangtse, on the southern side, is about 40 m. long and 30 broad. It is very shallow, with many picturesque islands. A peculiar feature of this lake is that, although shallow, mountains rise abruptly from its shore on the western side. The Tsauhu, on the northern side of the Yangtse, west of Nanking, is smaller. The Hungtsih, in Kiangsu, connects with the Yellow river, and lies between it and the Yangtse, 150 m. from the sea. The country between the mouths of the two rivers is so marshy and full of lakes as to suggest the idea that the whole was once an enormous estuary where their waters joined, or else that their deposits have filled up a large lake which once occupied this tract, leaving only a number of lesser sheets. The lakes of Yunnan are described by De Carné as particularly beautiful. That near which the capital city is built is the largest. Other small lakes are found in Chihli and Shantung.—The extent and excellence of the canals of China have been greatly vaunted, and it is in the construction of them that the Chinese have shown public spirit more than in any other direction. But considering the vast population of the empire, its internal commerce, and the character of the country, it is wonderful that they should have left the canal system so imperfect as it is. There are many districts of an alluvial character where canals are numerous. Some of them may be natural channels, lagoons, or bayous; others have been excavated for irrigation. The writer has seen a district where a field of 20 acres could not be found, the canals being so numerous. These of course could not have been formed for purposes of traffic. In these alluvial districts many of the canals, like the bayous of Louisiana, are broad streams which excite the admiration of the traveller. It is not uncommon to find canals near Shanghai from 50 to 150 yards wide and 6 to 10 ft. deep; and one may travel there 100 miles without meeting a lock. Those canals that may be considered artificial follow generally natural channels, and are subject to fluctua-

tions of the depth of water like other streams. They are as a rule imperfectly suited to the wants of commerce. The water in them is seldom quiet, and frequently, even when there is no special flood, boats can stem the current only with difficulty. In many cases, when floods occur, they become useless. They are sometimes broad streams, where the wind creates a sea. Sometimes the course of navigation lies across a lake. The tow-paths are seldom perfect, and very often the banks are not available for towing purposes. Transverse streams are not bridged by artificial waterways. Locks as constructed in the West are unknown in China. Sluices which confine the current, and inclined planes up which boats are pulled with the assistance of rude windlasses, are used instead. The Grand canal traverses the great plain from near Peking to its S. E. point. From near Peking to Tientsin it is formed by the northern affluent of the Pei-ho. From Tientsin to Lintsing, 300 m., it follows the southern affluent. From Lintsing to Tsining it is an artificial waterway; and thence to the Yangtse it follows the lake system. From the Yangtse to Soochow and Hangchow it is everywhere broad and generally of good depth. The artificial portion between Lintsing and Tsining is now out of repair and disused. In some places the canal is carried over valleys and marshy places by means of engineering works of considerable magnitude. Boats used on the canals of China are generally of small size, from 25 to 50 tons burden, and fitted with sails, which are used when the wind will serve. When it does not serve, the crew tow the craft by lines fastened to the mast head, or propel it with oars or poles. Despatch boats frequently traverse considerable distances at the rate of five or six miles an hour. The oarsman uses his feet to work a sweep, steering his boat with a small one operated by his hands. The junks used by officials of high grade are often very large and fitted with all the appliances of a comfortable home.—From what has been said of the rivers, lakes, and canals of China, it will be seen that they do not offer perfect communication with all parts of the empire. Beyond a doubt the transportation of passengers and merchandise was 50 years ago attended with fewer difficulties in China than in any other extensive region. Nature had contributed chiefly to this condition of things, and the government in a much less measure than western people have been led to believe. At the present moment the canals are so much out of order that there is a crying need for their improvement. At the best, however, the canals of China afford so imperfect a means of communication and transportation that they would not greatly forestall the usefulness of a system of railways. The vast, unwieldy, and disjointed empire can never realize a perfect harmony throughout her various and widely differing sections until railways have been introduced. A movement, supported it is be-

lieved by prominent men in the Chinese government, is now (1873) on foot for their introduction. The government is so far afraid of foreign influence that it will endeavor to keep those which may be constructed in its own hands.—There are few roads in China worthy to be mentioned. In the southern mountainous district no vehicles drawn by dumb animals are ever used. The same may be said of the districts where canals are common. In the provinces of Chihli, Shantung, Shansi, and Shensi carts are used for the transportation of produce and merchandise. Leading S. W. from Peking across the two provinces last named is a road which has been constructed over rugged mountains at no inconsiderable expense. De Carné mentions broad paved roads in Yunnan. It may be said of the roads of China, however, as of the canals, that they have not been constructed upon a comprehensive system, and that they serve their purposes in an indifferent manner.—The climate in so vast a country as China is of course various. At Peking, lat. 41°, there is no rain from November to April; the summers are long and hot, and the mercury ranges as high as 105° F., and as low as 6° below zero. At Shanghai, lat. 31°, rains occur throughout the year; the summer opens late, and lasts longer than in the same latitude on the coast of the United States; the atmosphere is charged with moisture, and the climate presents many of the features of that of New Orleans. At Canton the prevailing rains are in the colder months; the range of the thermometer is very great, and, although about the latitude of Havana, snow occasionally falls. The mean temperature of the whole coast is lower than in corresponding latitudes elsewhere. The climate is in the main excellent. The N. W. and S. W. districts of the empire are much affected by the cold diffused from the neighboring mountains and table lands. The central region is warmer than the coast in the same latitude. In eastern Szechuen Cooper saw peas in blossom in the early part of March, and the vegetation generally was a month or six weeks in advance of that at Shanghai. The fall of rain for China cannot be stated, as it varies in different localities. At Peking it does not exceed in average years 18 inches. At Canton it is about 70 inches. A monsoon sets down the coast from October to June, and up the coast from June to October. Sand storms are not infrequent at Peking; their effect is sometimes observed on the W. coast of Japan. Earthquakes have been experienced in different periods, but for the last 40 years have been as infrequent as on the Atlantic coast of the United States. The typhoons of the coast of China occur chiefly in the months of July, August, and September. Prof. T. B. Maury considers the monsoon of the coast of China “a part of a grand cyclone whose centre is stationary over the heated plains of central Asia, whose intro-moving winds, bearing the

evaporations of the Asiatic seas and oceans, feed it with meteoric fuel for six months in the year, and whose periphery may be regarded as embracing nearly one third of the entire eastern hemisphere;" and the active typhoon as incidental to the atmospheric disturbances so created. These storms are most frequent and severe in the neighborhood of Canton, and diminish in strength toward the north. None of the greatest severity have ever been experienced near Shanghai, but on the S. coast of Japan they sometimes rage fiercely. There is reason to believe that the climate of the northern part of the great plain has undergone change in the last 200 years. Many great bridges are found there, and marks of great erosion, where now water is seldom seen. The fertility of the country has doubtless decreased with the diminution of the rainfall, and this will explain the fact that the population of Peking and the surrounding country appears to be much less than it was formerly. — Considering the extent of territory, there is probably no region of the earth possessing soils of equal fertility to those of China. There is no desert land, and no district where the rainfall is not sufficient for the more or less abundant growth of vegetation. In respect of heat and moisture China is well favored for agricultural operations. Some of the alluvial districts have been in constant cultivation for many centuries and still produce excellent crops. The range of vegetable production is very great. Sugar cane is cultivated everywhere south of lat. 30°. The centre of its production is in Kwangtung. Rice is raised from one extreme of the empire to the other, but chiefly south of lat. 33°; the variety produced further north is cultivated without irrigation. Tobacco is also raised throughout the empire, and as far north in Mantchooria as the southern bend of the Amoor. Millet is the chief crop of the northern part of the great plain. Wheat, barley, maize, and sorghum are also raised. In Shingking pulse and wheat are the leading crops. In northwestern China rice, wheat, oats, maize, sorghum, and millet are raised. In central China rice is the leading product. In Szechuen there appears to be a wide range of production. Sugar is produced to such an extent that it competes at Hankow with that of the southern coast. Of late years the culture of the poppy has been introduced into this and the southwestern provinces, and has increased so largely that, in face of a growing consumption, the importation of Indian opium is not augmenting. The Szechuen drug sells at Shanghai at about 70 per cent. of the value of the Indian. Rice is the leading staple of the southwestern provinces. The article of produce in which foreigners are chiefly interested is tea. Green teas are produced in Chekiang, southern Nganhwui, and eastern Kiangsi; black in western Kiangsi, northern Hunan, Fokien, and southern Hupeh. Kwangtung produces both varieties, but chiefly the black. Next in

order of importance to foreigners is silk. That from the mulberry is produced in the southern and central parts of China and Szechuen, and as far north as lat. 33°. The centre of production is in the southern part of the great plain, near the mountains of the southeast. The silk-yielding varieties of the oak and ailanthus are found further north, extending into southern Mantchooria and Lower Mongolia. The zone of production includes Shantung in the east and Szechuen on the west. Cotton is raised in the valley of the Yangtse and throughout the country north of that river. The orange, lemon, pumelo, mango, pineapple, cashew, betel, loquat (*eriobotrya*), casambola, persimmon, and cocoanut are native fruits. Apples, pears, peaches, plums, and apricots are inferior in flavor and size to those produced in the West. Grapes are extensively cultivated in the north, and compare favorably with those of Europe or America. The *leguminosæ* afford many excellent vegetables and valuable products (indigo, soya, &c.). Peculiar to China are *dimocarpus litchi*, *dimocarpus longan*, *Cookia punctata*, and *pe-tsai*, a kind of white cabbage. The sacred bean of the Egyptians (*nelumbium speciosum*) is extensively cultivated as an article of food; so are several species of *aroidæ*, also the *sagittaria Sinensis*, a kind of arrowroot. The plantain fruit is less important in China than in South America. Ginger is extensively cultivated. The *chulan* plant (*chloranthus inconspicuus*), the tuberose, jasmine, and *olea fragrans* furnish the flowers which are used to scent some sorts of tea. A kind of grass (*phragmetas*) cultivated in the south is woven into floor matting. A species of *andropogon* and one of *arundo* are used by the poor for fuel. The bamboo is cultivated about villages for its shade and beauty, and is applied to such a vast variety of purposes that it may well be called the national plant of China. The tender shoots are used for food; the roots as a material for carved work; the culms as poles, rods, sticks, canes, joists, ribs of sails, shafts of spears, and tubes of aqueducts; the leaves as covering for persons and dwellings, and for manure; the shavings for mattress stuffings. India ink is manufactured from the soot of pines, fir, and other substances, mixed with glue or isinglass and scented. Seaweed is collected on the coast and used for industrial purposes (glues and varnishes) and for food. Large trees and timber are scarce. Oak, walnut, camphor, cedar, cypress, and varnish trees grow in the mountainous districts. Rosewood and ebony are not infrequent. The willow is a favorite plant in all parts of China. The chestnut, walnut, and hazelnut are all natives of China. The palm tree is cultivated for its leaves for fans, and the *kuan-lan* for its pith, which supplies an edible flour. The tallow tree resembles the birch, but the bark is white and the branches are slender; the fruit grows in bunches, each capsule enclosing three kernels, which are coat-

ed with tallow and contain an oil much used for the lamp, while the tallow is made into candles. The varnish tree resembles the ash; it exudes an essential oil which is poisonous to the touch. From a species of sycamore, paper is manufactured. Ginseng is found in the northwest, and is extravagantly esteemed, being administered as a universal panacea. Berries (currants, strawberries, raspberries, gooseberries) are seldom found.—Wild animals generally have long since disappeared from the more densely settled provinces. There are elephants, rhinoceroses, tapirs, wild boars, bears, tigers, leopards, and panthers, in the south; monkeys of a very large species (the gibbon) in the southwest; musk deer, wolves, lynxes, boars, gazelles, antelopes, in the west; squirrels, anteaters, sables, badgers, the jerboa, martens, porcupines, hedgehogs, marmots, weasels, in various parts of the country. Domestic animals are not kept so generally as in Europe or America, the Chinese disliking meat and dairy products for food, except pork. The hog and dog are the most common domestic animals. Horned cattle are kept only for draught; some of these are of a small black breed. The gray buffalo is also used. The horses are also small; jackasses and mules are preferred to them. Large-tailed sheep are imported from Mongolia, and are reared everywhere, but not to a great extent in the south. The goat is common in the northern provinces. The camel is used as a pack animal in the northernmost portion of the empire, but is rarely seen south of Peking. It is employed in war, and trained to carry small swivels on its back. The gold, the silver, Reeves's, and the medallion pheasants are indigenous to China. There are found, besides, the peacock, pelican, albatross, parrot, spoonbill, crane, heron, stork, curlew, cormorant, thrush, red-billed magpie, swan, grebe, geese, ducks, quails, and snipe. Crocodiles are not known in China, but small lizards and serpents abound. The common frog is caught in great numbers for food, as are tortoises and turtles. Besides all kinds of fish known in northern America, such as sturgeon, mullet, carp, trout, perch, pike, and eel, there are a great many peculiar to China, as the bynni carp (*polyne-mus tetractylus*), the *tsang-yu* or pomfret (*stromateus argenteus*), and the *sho-kia-yeu* (*tetrodon*). The goldfish (brought to Europe in 1611) is also a native of China. The fins of sharks and rays are eaten by the Chinese; they, in fact, eat nearly every living thing found in the water. The artificial rearing of fish, as also the artificial hatching of eggs, has been practised among the Chinese from time immemorial. Oysters of a good quality are common on the coast. Of insects, the silkworm, the wax insect, and the honey bee are the most important and useful. The white ant furnishes the whole nation with that article, which it deposits upon a tree called the *peh-lah shu*.—This great empire, so abundantly

favoured in the character of its soil, its temperate climate, and its physical configuration, is fortunate also in the extent and value of its mineral resources. The apathetic Chinaman has not even dreamed of the wealth which lies hidden under the hills and mountains of his native land, and the people of western states are only beginning to learn how desirable it is that this vast country shall open her fields of subterranean treasures to the enterprise of the world. So far as is now known, the northwest of China, as has been mentioned, is the leading mineral region of the empire. Of one of the provinces of this district Baron Richt-hofen says: "Shansi is one of the most remarkable coal and iron regions in the world. Some of the details which I shall give will make it patent that the world at the present rate of consumption of coal could be supplied for thousands of years from Shansi alone. Prof. Dana, in comparing the proportions of coal lands to the whole area in different countries, says that the state of Pennsylvania leads the world, its area of 46,000 sq. m. embracing 20,000 of coal land. It is very probable that on closer examination the province of Shansi in China, with an area of about 35,000 sq. m., will take the palm from Pennsylvania by a considerably more favorable proportion. But this is not all the advantage on the side of the China coal field; another is found in the ease and cheapness with which coal can be extracted on a large scale." It appears from his statements that iron ores are found near the coal in this province, and that the deposits are very extensive and the quality excellent. Williams and Pumpelly mention other valuable deposits in Shansi. Those of salt are remarkable, while copper, quicksilver, and silver are also noticed. It is probable that the mineral region extends across Shansi into the eastern part of Kansuh and southerly into Hunan. The abbé Huc speaks of coal in eastern Kansuh. The Chinese works consulted by Pumpelly confirm the abbé's statements, and show that coal is found so far west as lon. 104° E., and south to lat. 34°. The northern part of Hunan appears to possess extensive deposits of iron, and that metal is mentioned in the Chinese accounts as occurring in Shensi. A variety of precious stones are found in Shansi. The S. W. region of China is probably only less well favored with mineral deposits. Gold is found in the bed of the Yangtse. Copper, lead, silver, zinc, and tin have been extensively worked. De Carné says that before the present troubles Yunnan annually forwarded to the imperial treasury crude copper to the value of 1,000,000 francs, and that in peaceful times 1,200 men are employed in drawing off water from the argentiferous lead mines at Sinkaitseu. He considers Yunnan more richly endowed with mineral wealth than any other province. Coal is found in different parts of the southeast, but is mined largely only in southern Hunan and east of the Poyang lake in Kiangsi. The conditions under

which these deposits took place would appear to have been similar, but the first deposit is much greater than the other. There is reason to believe that iron ores are widely distributed in this region. There are two belts where the Chinese now smelt them. One lies S. E. of Ningpo, stretching away into Fokien; the other is situated in southern Hunan. The latter is likely to prove important. It is to be said of the deposits of coal and iron in S. E. China, that the failure of the Chinese to work them indicates that they do not occur under favorable conditions. Extensive coal fields are found in Shantung, and the gold-bearing quartz of this region may hereafter be a source of wealth. Coal abounds in the mountains which range away from the promontory of Liautung to the northeast; it is mined in Shingking. Iron ores are abundant, and until the advent of foreigners at Newchwang Manchooria was self-supplied with this useful metal. The presence of gold is asserted in Chinese works. The existence of coal in Szechuen has been spoken of, but it is doubtful whether it is widely distributed; Chinese accounts indicate that it is only found in the S. E. part of the province. Iron is mined in different parts of the province, and is cheap and abundant. Silver, copper, tin, and quicksilver are reported by the Chinese. Salt wells exist, which yield largely; the province is self-supplied, and was able to supply the markets of the adjoining provinces, E. and S., during the rebellion. Cooper relates that a gas sometimes escapes from these wells which will burn, and he infers that petroleum might be procured from the wells. Marble, porphyry, jasper, granite, and quartz are produced from the quarries of S. China. Lapis lazuli is found in the west. The crystal, ruby, amethyst, sapphire, topaz, turquoise, jade, garnet, opal, agate, jasper, and malachite are found. Sulphur exists in large deposits in Formosa. Notwithstanding the extensive supply of coal possessed by China, but little comparatively is mined. Difficulties of transportation and the heavy taxation combine to discourage mining operations. Until within a few years 90 per cent. of the coal used in foreign steamers on the coast was brought from foreign countries, notably from England. The people who live on the banks of the Yangtse cut reeds for fuel, while these rich deposits of coal exist not 200 m. away.—Of the aborigines of China only a few remnants are found (Miau-tze, or Lo-lo) in the mountains of the southern provinces. The present inhabitants migrated into the country from the northwest. The Chinese, or sons of Han, as they call themselves, are entirely different from the Caucasian race, and stand in near relation to the Mongolian. Their stature varies in different districts. At Canton the average height of adult males is estimated by Mr. Williams at 5 ft. 4. in. In the northern provinces it is probably somewhat greater. They are symmetrically built. The face is round, and the eyes

are small, having an oblique appearance, with bare lids, but thick brows; cheek bones high; nose small, and nearly even with the face at the root; forehead low; lips thicker than among Europeans, but not at all approaching those of the negro; hair straight and black; complexion yellowish brown. In the south they are swarthy, but not as much so as the Portuguese. Altogether their physiognomy is void of expression, and their general appearance not imposing. Stoutness, or rather obesity, is much admired; so are small feet and long finger nails. The Mantchoos are of a lighter complexion and slightly heavier build than the Chinese, have more beard, and their countenances indicate greater intellectual activity. As to the moral and intellectual characteristics of the Chinese, great injustice has been done to them. It is obvious that the trading populations of the large seaports cannot be considered fair specimens of the national character in general; and it is from these that travellers have taken their impressions of the people at large. The Chinese, so far as they have come in contact with Europeans and Americans, are industrious, skilful, polite, and provident. They have less personal courage than Europeans, and also a lower standard of morality. When aroused they are exceedingly cruel, yet they are not quick-tempered or revengeful. In the use of food and drink they are remarkably temperate. Their commercial enterprise is very great, and under more favorable conditions is likely to play a prominent part throughout the world. The Chinese are proud of their country and of their civilization, which was already flourishing at a time when the Christian nations had no existence. This national pride comes at least as natural to them as to those nations whom we are wont to call civilized. Considering that China contains about one third of the population of the globe; that, with the exception of steam engines and electric telegraphs, there is scarcely any great invention of modern times which has not been in use among the Chinese for many centuries; that popular education is more general and the social structure more firmly settled in China than in any other country, their overbearing demeanor and narrow-mindedness in regard to foreigners may at least appear natural. It is probable that a more intimate intercourse with them will be apt to modify in some respects the unfavorable opinion which has prevailed among Christian nations of the character of the Chinese. "Their civilization," says Williams, "has been developed under peculiar forms and influences, and must be compared to, rather than judged of by that of Europeans; the dissimilarity is as wide, perhaps, as can possibly exist between two races of beings having the same common nature and wants. A people by whom some of the most important inventions of modern Europe were anticipated (such as the compass, porcelain, gunpowder, paper, printing), and were known

and practised many centuries earlier; who probably amount to more than 300,000,000, united in one system of manners, letters, and policy; whose cities and capitals rival in numbers the greatest metropolises of any age; who have not only covered the earth but the waters with towns and streets—such a nation must occupy a conspicuous place in the history of mankind, and the study of their character and condition commends itself to every well-wisher of his race.” The difficulties with which this study is beset are shown by the great diversity of opinion among those travellers who have ventured beyond the immediate vicinity of the large seaports, and improved every opportunity to get an insight into the peculiarities of their social system and national character. The tendency of recent observers, however, is to judge of them in a more appreciative way, and to explain their peculiarities by a consideration of the circumstances of their history and training. If they are vain, they have been isolated; if they are cowardly, they have had a great measure of peace; if they lack boldness in enterprise and the disposition to organize for great purposes, the government has not favored the accumulation of money or power in the hands of the common people; if they are immobile, the mass is great, and the structure of the written language is so difficult that it is mastered only by a small percentage of the population, and as a consequence the diffusion of intelligence is difficult; if they are atheistical, their religions have not been such as to commend them entirely either to their judgment or their affection.—The domestic and social life of the Chinese has perhaps more features in common with western nations than that of other oriental peoples. Although polygamy exists among the wealthier classes, and their women generally live in seclusion, family life is much esteemed and cultivated among them. The first wife has the full control of the household, while the concubines are little more than servants and housemaids. The Chinese illustrate the relation by comparing the wife to the moon and the concubines to the stars, both of which in their appropriate spheres revolve around the sun. The utmost respect and obedience to the behests of their parents are enjoined to children. The betrothment of the children is entirely in the hands of the parents, and the obligation of the former to fulfil the contract made by the latter is enforced by law, even to the annulling of an agreement made by a son himself in ignorance of the arrangements of his parents. Cleanliness is not among the virtues of the Chinese, either in regard to their habitations or their persons. The poorest people do not change their garments until they are worn out. Their houses are generally low, the roofshipped, and the catenary curve of their edges shows that the tent is the type of the dwelling. But in size, style of building, and the arrangements of the interior, there is every variety,

from the squalid hovel to the pretentious palace. Even the best houses are poorly ventilated and lighted; the appearance of the rooms would be cheerless and uncomfortable without the gay and costly furniture and variety of ornaments. The little parks connected with the mansions of the wealthier classes are laid out in tasteful style. The streets in Chinese cities are extremely crooked and narrow; few of them exceed 10 or 12 ft. in width, and most of those in Canton are less than 8 ft. No public squares relieve the closeness of these lanes. Ventilation is, of course, very imperfect; drainage is only partially attended to, and the sewers frequently exude their contents over the pathway. Add to this the fact that offal and manure are carried through the streets by the scavengers, and we can understand the bad odor in which Chinese cities are held, and also the prevalence of ophthalmic diseases among the people. These narrow streets present a singularly animated spectacle to strangers. Itinerant workmen abound; blacksmiths, tinkers, glass menders, barbers, druggists, shoemakers and cobblers, fortune tellers, herb sellers, book sellers, money changers, and many other tradesmen, keep their movable establishments in the streets. Still, great as the bustle and crowds sometimes are, altercations or collisions are rare, and at night a remarkable quiet prevails. Ordinarily, conflagrations are soon got under. Fire engines of an imperfect construction are used, and buildings are pulled down and the inflammable materials withdrawn. The dress of the Chinese is neither so uniform nor so unchanging as is generally supposed. Fashions alter there as well as elsewhere, but not so rapidly as among European nations. If it were not for the shaven crown and braided tail of the men, and the crippled feet of the women, little fault could be found with their costume, combining as it does warmth and ease. The fabrics most worn are silk, cotton, and linen for summer, with the addition of furs and skins in the winter. The winter garments of the poor are made chiefly of padded and quilted cotton materials. The garments of the sexes differ more by their colors than by their shape and cut. Inner and outer tunics made of cotton or silk, a pair of loose trousers over which tight leggings are pulled in winter, and shoes with thick felt soles, are the principal articles of dress. The diet of the Chinese is sufficient in variety, wholesome, and well cooked, though many of their dishes would appear insipid to the taste of Europeans and Americans. The proportion of animal food consumed is probably smaller among them than among any other race in the same latitudes. Cookery is almost esteemed as a science in China. Mr. Wingrove Cooke assigns to the Chinese in cookery a middle position, below the French and above the English. The Chinaman considers the Englishman's mode of feeding the nearest approach to that of the savages of Formosa; for, says he,

"the Englishman does the chief work of the slaughterhouse upon his dinner table, and he remits the principal work of the kitchen to his stomach." The Chinese cook is anxious to disguise the original shape and appearance of the food as much as possible. He discards spices, and uses oils and fats. Many strange articles of food are eaten, but they are generally prepared in such a manner as to appear palatable to unprejudiced foreigners. Coffee, chocolate, beer, cider, porter, and brandy are unknown; their common beverages are tea and a spirit distilled from rice. Wines are almost unknown. The native tobacco is of an inferior quality; it is not chewed, but smoked or used as snuff. The pernicious habit of opium smoking prevails among all classes, and is spreading year by year, in spite of the earnest efforts of the government to prevent it. The social life of the Chinese is generally described as a mass of ceremonials and cold formalities, devoid of all real kindness of heart; but this opinion is based upon incomplete observations. In their common intercourse the Chinese are not more formal than is elsewhere considered to be well-bred; it is on extraordinary or official occasions that they observe the precise etiquette for which they are famous. Whether in the crowded and narrow thoroughfares, the village green, the bustling market, the jostling ferry, or the thronged procession, wherever the people are assembled promiscuously, good humor and courtesy are observable. Street fights, assaults, and murders are not common excepting in disturbed districts. The people are fond of processions and public shows, and celebrate several imposing popular festivals. The new-year's time, the festival of the dragon boats, the feast of lanterns, the fishermen's festival, &c., are occasions of general rejoicing and merrymaking. Gambling is universal. The violent and gladiatorial sports of other countries are held in contempt. Duels are unknown among them, and they consider a resort to force as proof of an inferior kind of civilization.—The subjoined table of the population of China is taken from the "Middle Kingdom" of Dr. Williams, who esteems the several estimates the result of regular censuses, and the only ones which may be relied upon as such. The reader is referred to that book for an elaborate and able discussion of those estimates. Taking the census of 1812 as a basis, and estimating an increase of only 20 per cent. in 60 years, the present population of China would be about 450,000,000. For the last 20 years the empire has been ravaged by internal war, and it is probable that there has been an actual decrease in its numbers. An increase of 20 per cent. would not be a large one for the preceding 40 years, and allowing a decrease amounting to 50,000,000, the present population would reach 400,000,000. The observations of recent travellers would indicate that this number is far above the true one. Baron Riechhofen, for instance, is disposed to believe that

AREA AND POPULATION.

PROVINCES.	Area in English square miles.	Pop. to sq. m. by last census.	Census of 1711.	Census of 1783.	Census of 1812.
Chihli.....	58,949	475	3,274,870	9,374,217	27,990,871

Total.....	1,297,999	265	28,605,716	103,050,060	362,447,183

Chekiang, set down in the table as having 26,000,000 in 1812, does not now contain more than 8,000,000. But it is dangerous to take an arbitrary calculation in such matters. The traveller sees the country for a little distance on either side of his track. He makes no count. To declare a census wrong upon such evidence would be very bold. It is to be remembered that the censuses of China have been taken for governmental purposes, and were not intended for the information of foreigners. In other statistics the Chinese records have been found quite accurate, and why should they not be in this direction? The question whether China is overpopulated does not turn upon an enumeration of the people. It is certainly known that there is no considerable district where, having regard either to the extent of land brought under cultivation, or to the methods adopted, tillage is carried to the furthest point. As but few animals are reared or used, the soil will support a larger number of people than in Europe or America, where no inconsiderable proportion of the produce is consumed by stock, and where owing to the wasteful habits of the people the best use is not made of that reserved for food. In Manchooria and Mongolia, and in the more unpromising regions of Koko-nor and Thibet, the population is a mere fraction of what it might be. Extensive districts near the Yellow river are subject to floods and practically abandoned, which under an efficient government would be quite safe for the operations of husbandry. In western Chihli, the use of coal would admit of the growth of trees, and perhaps bring back the rainfall of former centuries; and elsewhere the presence of trees might save the land from destructive erosion. In a country where the methods and means of transportation are imperfect, any given district is practically isolated, and the disaster of a drought or flood becomes more serious. The drought of 1871 destroyed a large portion of the crops of the S. E. provinces,

while the rain precipitated a flood in the N. E. Foreign vessels were able to supply the country of the former region, but the other was inaccessible during the succeeding winter months by reason of the presence of ice, and many people died from starvation. This could not however be taken as an indication of over population. The climates and soils of China are so diverse that a famine in any district can only be disastrous as a result of a failure of transportation.—The Chinese speak but one language, but of course the aborigines still found in southern China, and those of Formosa and Hainan, have their own tongues. The spoken language has many dialects. It is not uncommon to find marked differences of pronunciation on the different sides of a mountain range or of a stream. These differences are so great that difficulty is experienced by the Chinese of one section in understanding the speech of those from another district. The written language is the same everywhere. A special article is devoted to the Chinese language and literature, but it may be said here that the language presents a great bar to the progress of the empire. More time is consumed by Chinese students in mastering the written language than is given in the countries of the West to the acquirement of a liberal education. The celebrated literary examinations of China are directed to the inquiry whether the candidates can read and write with readiness and grace. The acquisition of general or special knowledge is not thought of, and the masses are kept in a state of degraded ignorance.—The principal occupation of the Chinese is agriculture, which next to letters they consider the most honorable of all. In order to remind the people that agriculture is the basis of society, the emperor himself and the viceroys of the provinces once in every year perform the ceremony of ploughing some furrows and sowing one of the grains. Nowhere is the soil cultivated more carefully and diligently. The implements used in their agriculture are very rude. The system of irrigation is perfect, and the great importance of manuring is fully appreciated. As the scarcity of domestic animals prevents the application of stable manures on a large scale, all refuse applicable to the purpose is carefully collected. Human ordure, ashes, muck, gypsum, offal, hair (even the barbers gathering the product of their tonsorial performances, and selling it to the farmers), and whatever other matters can invigorate the soil, are freely used. The density of the population rendering it impracticable to let the fields lie fallow, and the rotation of crops not being well understood, the Chinese sustain the productiveness of the soil chiefly by constant manuring. In the fertile country between the Yellow and Yang-tse rivers and south of the latter, two crops are obtained from the same field in one year. The threshing of the grain is performed either by treading or by rollers and flails. The sedge in the marshes and grass on the hills are collected

for fodder and fuel, but it is believed not a single acre of land is sown with grass seed. Cattle raising is, therefore, the most unimportant part of the farming business. The flesh of domestic animals is rarely used for food, the hog, and in the north mutton, excepted. Butter and cheese are not made at all. Poultry furnishes the favorite meat for all classes of the population. The fields of different owners are not, as in America and England, separated by fences, walls, or hedgerows; and hence the cultivated plain appears like a vast garden, in which the plats seem to be mere beds. Hunting is profitable only in the mountainous districts of the west and southwest; there are no game laws in China. The skill exhibited by the Chinese in their various modes of catching and rearing fish is admirable. One tenth of the population derive their food from the water. Great numbers of cormorants are trained to catch fish.—The progress of the Chinese in the mechanical arts is slow; their imitative faculty having in the course of time become stronger than the inventive, they cling to their ancient implements and designs, and are slow to adopt improvements in either. But their obstinacy in this respect has been very much exaggerated. They do not greatly feel the want of improved machinery, since labor is so cheap that it would even appear cruel to replace it by mechanical forces. In the arts of metallurgy they have attained only to mediocrity, except in the alloying of metals, and in chased or carved work in gold and silver, in both of which they excel. In the manufacture of glass, though it has been but recently introduced, they are making good progress. Their porcelain was a century ago unequalled; but the quality, styles, and finish are far below the standard of that now produced in Europe, and their patterns never have compared with those of the classic ages of Europe. The manufacture of silk is original among the Chinese, and in some directions foreigners have not yet succeeded in fully equalling their products. A durable cotton cloth (nankeen) is made in the central provinces. The consumption of leather is small, and it is porous and tender in consequence of the rapid manner in which the tanning process is completed. The only woollen fabrics of the Chinese are felt for soles and hats and a sort of rug. Their carved work in ivory, wood, and horn is exquisitely delicate. The Chinese mechanics of different trades are accustomed to form associations with certain rules and regulations, but these are submitted to voluntarily, no restraint being imposed by the state on the liberty of trade. Handicraftsmen of every trade wander through the streets of cities and villages, carrying their implements with them, ready to do every job on the spot.—The Chinese are eminently a trading people; their merchants are acute, methodical, sagacious, and enterprising, not overscrupulous as to their mercantile honesty in small transactions, but in large dealings exhibiting that

regard for character in the fulfilment of their obligations which extensive commercial engagements usually produce. The inland commerce of China is undoubtedly of stupendous dimensions. It has been asserted that there is a greater amount of tonnage belonging to the Chinese than to all other nations combined. Myriads of freight boats are constantly plying upon the gigantic network of natural and artificial water communications. To obtain accurate statistical tables on the value of the inland commerce is impossible. The principal articles of export are tea, raw silk and silk goods, straw goods, mats, porcelain and lacquered ware, fire crackers, fans, sweetmeats, rattan, grass cloth, vegetable tallow, pictures, and others which singly form only trifling items in the trade, while their aggregate value is considerable. The principal articles of import are opium, longcloths, domestics and sheetings, ginseng, tin, lead, iron in the form of bars, rods, and hoops, woollen goods, and petroleum. Tripang, birds' nests, sharks' fins, and fish maws are imported as articles of food from the Indian archipelago; precious stones and pearls from India or central Asia. Rhinoceros horns are brought from Burmah and Sumatra. Gold and silver thread is largely imported for embroidery. The importation of metals has steadily increased with the enlargement of the trade. Fine furs are chiefly brought from Mantchooria and Siberia. Among the most salable articles of foreign manufacture are umbrellas, needles, clocks and watches, cheap jewelry, telescopes, cutlery, snuff, corks, glass ware, lamps, and chandeliers. Up to 1842 Canton was the only port open to Europeans, and the intercourse was carried on through mercantile companies who had a monopoly of the trade. Since then four other ports, Amoy, Foochow, Ningpo, and Shanghai, have been made available to Europeans and Americans, and nine additional ports were added to the list by the treaties negotiated at Tientsin in June, 1858. Steamers and sailing vessels belonging to foreigners are admitted to the coasting trade and upon the Yangtse river, but they are allowed to visit only the ports named in the treaties. Foreigners can acquire land and houses at the ports, and may travel in the interior for purposes of pleasure or for trade, but must use the conveyances of the country. Produce may be brought from the interior by paying at the port of destination a duty which is equal to one half the duty upon exportation. This half duty is a commutation of the native levies exacted in the several provinces, and comprises a part of the provincial revenue. Foreign merchandise may be sent into the interior under a similar system. Opium can be brought to the ports by foreigners, but cannot be transported into the interior by them or by their agents, and after leaving the ports is subject to such duties as the authorities may see fit to impose. All duties upon goods or produce imported or exported by foreigners are fixed by treaty stipu-

lations between China and foreign powers, and cannot be varied without the consent of the latter. Foreigners are exempted from the jurisdiction of the Chinese government and made subject to the functionaries of their respective states, but may be arrested by the native authorities. At most of the ports districts are set apart for their residence, and they are permitted to establish their own regulations for the police, sanitary, and other control of their settlements. Shanghai is considered by its residents a "model settlement." It supports a considerable police force, and maintains order among about 5,000 foreign and 70,000 native residents. It has many of the attributes of a free city. The telegraph has been completed to Shanghai by two routes, *via* India and Singapore, and *via* Siberia and Japan. Some short local lines are working in the foreign settlement at Shanghai, and their operations are becoming familiar to the Chinese, who are evincing a disposition to introduce them throughout the empire. No foreign machinery has been used in the mines of China, and their processes of extracting ores and of smelting and working them are rude. The revenues derived from the trade conducted in foreign bottoms are collected by customs authorities, consisting of foreigners and natives, the former controlling. This system was introduced at Shanghai in 1855, as a means of checking the corruption of the native customs officers, and has extended to all the ports where foreigners are concerned. Mr. Robert Hart is at the head of the whole system, and is credited with being an adviser of the government in all its affairs with western states. That official deserves credit for having so managed his trust as to consult the rights of people of all nationalities, and to build up one of the most efficient customs establishments in the world. The establishment of lighthouses on the coast is chiefly due to Mr. Hart. His subordinates at the ports have been carefully chosen, and their annual contributions to the fund of information regarding their several districts are printed at the expense of the customs department. The matter printed already amounts to a considerable mass. Medical officers are employed at the several customs agencies, and their reports are also published. There are no chartered banks in China. Private banks are numerous. Insurance companies are unknown among the natives, but foreign companies at the open ports receive support from the native merchants. Paper money, formerly issued in immense quantities, is now almost unknown as a general circulating medium, excepting in the northern provinces. Loan offices and pawnbrokers' shops are numerous. The legal interest allowed on small loans is 3 per cent. per month, but among business men 10 or 15 per cent. per annum is the usual rate. The monetary system is arranged on the principle of weight, and the foreign names *tael*, *mace*, *condareen*, and *cash* are applied to the divisions,

though the cash (*tsien*) is the only native coin now current, while Mexican dollars are employed as a commercial medium along the coast. The tael (equal to 10 mace, or 100 candareens, or 1,000 cash) varies in different parts of the empire. At Shanghai the intrinsic value of a Mexican dollar is esteemed $\frac{7.25}{1000}$ of a tael. This would make the tael about \$1.39 Mexican. The market value of the Mexican dollar fluctuates from .72 to .82; an average value is about .75. The Carolus dollar, formerly much used, passed for a considerable period as the equivalent of the tael. It is now seldom seen in China. The native bullion is called *sycee*, and the ingots weigh from 5 to 50 taels. The tael (*liang*), catty (*kin*), and pecul (*tan*) are the weights commonly employed. The catty is $1\frac{1}{2}$ lb. avoirdupois, the tael $1\frac{1}{2}$ oz., and the pecul $133\frac{1}{2}$ lbs. Of long measures, the *chih* or foot is the unit of length (according to the tariff, 14.1 inches English). It is subdivided into 10 *tsun*, and each *tsun* into 10 *fan*. The decimal division runs through nearly all the Chinese weights and measures. The Chinese mile (*li*) is 0.3576 of the statute mile. The land measures are the *mau*, *fun* ($\frac{1}{10}$ of the mau), *li* ($\frac{1}{10}$ fun), and *haru* ($\frac{1}{10}$ li). The usual mau is about 7,000 square feet; 100 mau make a *king*.—The following tables exhibit the trade of China with the countries named for the year 1871, the values being expressed in Shanghai taels (1 tael equals about \$1.40 gold). They are taken from reports published by Mr. Hart, and show the trade carried on under foreign flags at the open or treaty ports. No accurate exhibit of the trade of China can be made in the absence of data regarding that of Hong Kong, or that carried on with Hong Kong under the native flag. It should be mentioned also that Hong Kong produces nothing and consumes but little, and that the merchandise exchanged with the colony comes from or is destined for Great Britain, America, India, the Straits, &c.

The aggregate number of entrances and clearances of foreign vessels at the treaty ports in 1871 was 14,963; total tonnage, 7,381,557. Of the vessels 7,160, with a tonnage of 3,330,881, were British; 4,600, of 3,187,643 tons, were American; and 1,480, of 428,747 tons, were German.—The Chinese exhibit but little disposition to emigrate, and considering the vast population of the empire but few are found outside of its borders. The migration to Java, Siam, and the straits of Malacca has extended

* The value of the opium imported into Hong Kong over that imported into the open ports and stated above is 16,256,056 taels. All or nearly all of this excess ultimately reaches China.

over a considerable period. The producing class in Java is largely Chinese, and it is stated that they compose one third of the population of Bangkok in Siam. In Mantchooria the Chinese element is so great that the language of the country is dying out. In Mongolia the "labors of the Chinese farmers steal forward like a snake in the grass." Chinese traders find their way to the great marts of central Asia. Emigration to distant countries by the way of the sea has been opened within the last 25 years. The greatest flow has been to the Pacific coast of the United States, and next after that to Australia. This emigration has been perfectly voluntary in its character. That to Peru and the West Indies has been promoted by foreigners and attended with horrors scarcely second to those of the African slave trade. It is said that a ship has been burned off the Chinese coast each year for a considerable period by the coolies on board, who have preferred to meet death in this manner to being carried into a condition of slavery. The history of the race and their timid character indicate that there is no occasion for the fear that they will come to this country in great numbers. Efforts to introduce them into the southern states have proved unsuccessful. As laborers they are less vigorous than the negroes; and as the latter possess political power, they are likely to use it against the Chinaman if he becomes a competitor in the labor market. The Chinese who have gone to the regions near China have settled in them with their families; but those who have come to this country do not seem to regard it as a permanent abode, and they even send back to the mother land the bones of those who die. As a laborer, the Chinaman, though lacking vigor, is constant, and he brings to his labors an element of intelligence which produces good results. Those who worked on the Central Pacific railroad were skilfully managed and pronounced eminently satisfactory. The following table, which exhibits the Chinese immigration into the United States to June 30, 1873, is compiled from the reports of the bureau of statistics, except for the period prior to 1855, for which the figures are taken from a letter of Daniel Cleveland of San Francisco, published in the "United States Diplomatic Correspondence" for 1868:

YEARS.	Number.	YEARS.	Number.	YEARS.	Number.	YEARS.	Number.

Total							169,084

To July 1, 1868, it is estimated that 45,887 had returned to China. The United States, accord-

ing to the census of 1870, contained 63,199 Chinese, of whom only 4,566 were females. In British Columbia there were 1,548 in 1871. Victoria contains the greater portion of the Chinese in Australia, and in that colony they numbered 17,705 in 1871. (See COOLY.)—In no country of the world is education held in higher honor than in China. Though the government fosters it only by making it the road to distinction and by supporting the various examinations (*hio-kung*), the knowledge of reading, writing, and arithmetic, to a greater or less degree of proficiency, is all but universal. But as there is no alphabet in the language, and words are represented by what may be termed arbitrary symbols, the written language is one of which more or less may be acquired, and a certain mastery of it does not presuppose the mastery of the whole. Thus a merchant may know the symbols for the articles which he sells and the numerals, so as to be able to keep his accounts, and yet have no ability to read the contents of an ordinary book. The number of adult males who can read the classical books with readiness is probably not more than three in a hundred; of women, one in a thousand. The quality of the knowledge dispensed in Chinese schools must not of course be judged by the requirements of western nations. There are four literary degrees, the first of which is called *siu-tsai* (flowering talent), corresponding to the bachelorship of arts; the second *ku-jin*, or licentiate; the third *tsin-sze*, or doctor; the fourth *han-lin*, or member of the imperial academy. The examinations which the aspirants to public honors have to pass are very severe. Bribery is sometimes, but it is believed rarely, practised to attain the degrees. The unsuccessful candidates are numbered by hundreds of thousands; they get employment as school teachers, notaries, clerks, letter writers, &c. Literary attainments are considered creditable to women, and the number of authoresses is by no means small. Printed books are cheaper in China than elsewhere, notwithstanding the clumsiness of the printing apparatus. Knowledge centres in a mere acquaintance with the aphorisms of the classics. Sir John Davis justly compares the state of the sciences among them with their condition in Europe previous to the adoption of the inductive mode of investigation. In mathematics they have made some progress since they became acquainted with European mathematical works. Astronomy has not yet been emancipated from astrology. Their geographical knowledge is mainly limited to their own country, though recently some Chinese scholars have adopted more correct ideas on this subject. A school known as the university of Peking was established in 1868, for the purpose of instructing Chinese youth in the various branches of western knowledge. The teachers are from different countries. The university has encountered many difficulties, and as yet is hardly worthy

to be dignified by the name. It however contains the elements of usefulness, and will not be neglected by the representatives of western states at the capital. The Roman Catholic missionaries have established no fewer than 25 considerable schools, one of which, at Shanghai, numbers over 300 pupils. The Protestant missionaries are doing much work of this sort. In 1872 the government sent 30 students to the United States, and 30 more are to come each year for the succeeding four years, in all 150. They are to be thoroughly educated in special branches, and are promised official employment on their return to China. A sum of about \$2,000,000 has been appropriated for the purposes of the mission. In the fine arts, the æsthetic feeling of the Chinese has been developed in a manner so peculiar as to defy all direct comparison with Christian art. While the skilful workmanship in sculpture, paintings, and architecture may justly be admired, the designs are mostly grotesque and incongruous. No higher standard seems to exist than mere mechanical skill; there is scarcely any vestige of an effort to realize the idea of the truly beautiful and sublime. Chinese artists are able to copy European works with admirable accuracy, but they do not appreciate them, or consider them as models worthy of imitation. In landscape gardening they excel, but their singular predilection for dwarfish and stunted forms mars the effect of their designs. Their music is painfully discordant to cultivated ears. They have a great many stringed and wind instruments, besides drums, bells, &c.; but of accord, rhythm, harmony, and melody they have no adequate conception. "The gong is the type of Chinese music: a crashing harangue of rapid blows upon it, with a rattling accompaniment of small drums, and a crackling symphony of shrill notes from the clarinet and cymbal, constitute the chief features of their musical performances. Their vocal music is generally on a high falsetto key, somewhere between a squeal and a scream." Dancing they set down as a branch of the dramatic art. How Europeans or Americans can enjoy dancing themselves instead of having it done by professionals is utterly incomprehensible to the Chinese mind. The drama is very popular among all classes of Chinese society, but officials are not permitted to witness theatrical performances because of the vulgarity and obscenity by which the plays are sometimes, though not generally, characterized. The actors are not respected. Women are not allowed to appear on the stage; their parts are played by beardless youths or eunuchs. Only in the northern and eastern provinces are permanent theatres to be found. The lower classes are very fond of theatrical entertainments, and, as in ancient Rome, there is no shorter road to popularity than the furnishing of gratuitous performances to the people.—Indifference to religious matters is a prominent

national trait of character. They have not even a general term corresponding to the word religion; *kiao*, the word that comes nearest to it, meaning only doctrine or creed. The lower classes are mostly professors of an adulterated kind of Buddhism, which in the lapse of time has sunk to coarse paganism and idolatry. The priests of this profession, over 1,000,000 in number, are for the greatest part ignorant and have no great reputation for virtue. They beg around the country and live in monasteries. The higher classes are either believers in the doctrines of Confucius, or in those of the philosopher Lao-tse. These are scarcely more than systems of moral philosophy clothed in a fantastical symbolism. Thus Confucius teaches that from the original substance (*Tai-ki*) two principles emanate: Yang, the principle of perfection, of the heavenly, of light and warmth, the masculine, symbolized by —; and Yin, the feminine principle, or that of imperfection, of the terrestrial, of darkness and cold, symbolized by — —. By the combination of these symbols four images (*sz'-siang*) are presented, viz.: — — — —, corresponding to the four cardinal virtues, piety, morality, justice, and wisdom. From a double combination result eight signs (*kua*), viz.: — — — — heaven, — — — — moistness, — — — — fire, — — — — winds, — — — — water, — — — — mountains, — — — — thunder, — — — — earth. By the aid of these symbols, arranged in the form of a circle, Confucius describes the universe, and, making them to correspond with moral and mental properties, constructs an ethical system, scarcely to be styled a religion. Lao-tse (born 604 B. C., 54 years before Confucius) founded the religion of the Tao (supreme reason), which, according to him, is anterior to and the source of the divinities (Ki, Hi, Kuei) and all material forms. Like Zeno, he recommends retirement and contemplation as the most effectual means of purifying our spiritual nature. The professors of this religion (*Tao-sze*, usually rendered rationalists) believe in the existence of a spiritual world, in spiritual manifestations, and a migration of souls. There are 1,500 temples devoted to Confucius attached to the examination halls. The priests of the Tao religion live in temples and small communities with their families, or lead a wandering life, deriving a precarious livelihood from the sale of charms. They have degenerated very much, and are commonly looked upon as ignorant cheats or jugglers. The Buddhists, or the followers of Fo, have the largest number of temples, but the great mass of the people offer their prayers in any temple indiscriminately, and are perfectly indifferent to the diversities of religious denominations. "Buddhism in China," says Dr. Morrison, "is decried by the learned, laughed at by the profligate, yet followed by all." No religion is taught in the common schools. The one creed upon which all agree is the worship of deceased ancestors. The Tai-ping insurgents attempted to found a new re-

ligion, which was a curious mixture of the oldest Chinese religion and Christian doctrines; it recognized divine revelation as still continuing; its professors were fanatical and intolerant propagandists. Christianity appears to have found adherents in China at an early date. It is certain that the Nestorians had flourishing missions which began in the 7th century, and certainly existed till 1330, when they were reported to number about 30,000 souls. The first Roman Catholic mission was established by Johannes de Monte Corvino. He was made archbishop by Pope Clement V. in 1305, and seven suffragan bishops were sent to his assistance. After the final establishment of the Ming dynasty almost nothing is known of the Catholics or the Nestorians. The Catholic missions were reestablished in the second half of the 16th century, chiefly by Jesuits, and have been maintained ever since, but with varying success and influence. The Roman Catholic population of China is estimated by Hue at 700,000. The estimates of other Catholic missionaries vary from 400,000 to 1,000,000. Since the treaty with France of 1858 the Catholic congregations have received large accessions, and the church property has been greatly increased, chiefly by the recovery of estates previously seized by the government or lapsed through the hostility of the people. At the close of 1872 there were in China proper 26 vicariates apostolic and three prefectures apostolic, and in Chinese dependencies three vicariates. The first Protestant mission was begun in 1807 by the London missionary society, since when a number of other societies, English, American, and German, have sent out missionaries. The Protestant missions have been confined until lately to the open ports. In 1869 they had an aggregate membership of 5,624. A mission of the Greek church was established under Peter the Great, and in 1872 numbered a few hundred converts. The Mohammedans number many millions; there are at least 200,000 in Peking alone.—The form of government is monarchical, but not despotical, since the emperor is bound by ancient laws and customs, and could scarcely without danger disregard the advice or remonstrances of his ministers or the boards of administration. The official title of the emperor is *hwang-ti*, autocrat, as nearly as it can be translated. His real name is never used while he lives, but the period of his reign has a special name expressive of its character and tendencies. The emperor designates himself by the terms *kua-jin*, the solitary or unequalled man, and *kua-kiun*, the solitary prince. His throne is called "the dragon's throne." Like all oriental princes, his person is venerated in an extreme manner. He never appears in public unless preceded by a large body guard. His courtiers and chamberlains are for the most part eunuchs, of whom perhaps 1,000 are connected with the palace. He has one legitimate wife (*hwang-hoi*, empress), two wives of an inferior rank

(*fu-shin*, queens), and a great number of concubines. The emperor makes choice of his successor from among the sons of his three wives, but the selection remains a secret until his death. The daughters are married to Mongolian or Mantchoo princes. Every succeeding generation of the imperial offspring stands one grade lower in the ranks of nobility, until at the seventh remove they belong to the people at large, but are governed by a special board called board of the imperial clan. Only the highest classes of princes are obliged to live at court. Besides this nobility of birth, there is a personal dignity generally connected with official rank, to which every one has access irrespective of birth. The five ancient degrees of dignity are *kung*, *han*, *pe*, *tse*, and *nan*, sometimes rendered duke, marquis, earl, viscount, and baron. The mark of official nobility is the peacock's feather. Titular rank is sold to ambitious individuals, in the same manner as official titles, such as aulic councillor, secret councillor, &c., in some German states. The civil mandarins number about 15,000, the military about 20,000. Each are divided into nine classes, and rank alike. Officials of the first rank wear a ruby placed on the apex of the hat; those of the second a red coral button; those of the third a sapphire; those of the fourth a blue opaque stone; those of the fifth a crystal; those of the sixth a white shell button; those of the seventh one of plain gold; those of the eighth one of worked gold; and those of the ninth one of worked silver. There are additional indications of rank embroidered on the garments worn, which differ in the civil and military grades. The administration of the imperial government is complicated. A cabinet (*nui-kau*), consisting of four chief chancellors and a number of assessors, has the general superintendence and legislative regulation of the country. Two of the members of this board are Mantchoos and two Chinese. The former have a veto upon the latter. The emperor himself takes a prominent part in the labors of this board. Of late a portion of its powers has been vested in a cabinet council of five members only (*kiun-ki-chu*), which corresponds to the ministry of western nations. Its members are selected by the emperor from the functionaries of the highest rank. The duties of these supreme councils are general, comprising matters relating to all departments of the government. The principal executive bodies under them are the six boards (*luh-pu*), viz.: 1, board of civil service (*li-pu*); 2, board of revenue (*hu-pu*); 3, board of rites (*li-pu*), or imperial household, court matters, and diplomacy; 4, board of war (*ping-pu*); 5, board of justice (*hing-pu*), performing also the functions of a supreme court of appeals (*ta-li-se*); 6, board of public works (*kung-pu*). Each department has two presidents, four vice presidents (one half Chinese, the other Mantchoos), and three subordinate grades of officers (directors, under-secretaries, and controllers), besides

a great number of clerks; but no board is entirely independent of the others in its acts. An institution peculiar to China is the censorate (*tu-cha-yuen*, i. e., all-examining court), whose duty it is to examine all official acts of the ministry and cabinet, to institute inquiries, raise objections to such measures as they deem detrimental to the best interests of the country, and even to stop them entirely. They are bound to give a hearing to every subject who has cause to complain of any act of government. The office, in its practical working, is somewhat similar to that of the tribunes of the people in ancient Rome, and may be considered a substitute for popular representation. At least, the privilege of reproving even the doings of the emperor has often been exercised by the censors with candor and plainness. The administration of the vassal states and foreign affairs is separate from that of the empire proper. It is intrusted to the *li-fan-yuen*, usually called the colonial office. Since the treaties of 1858 a separate office for the transaction of business with the western states has been established; it is known as the *tsung-li yamen*. The provinces are divided into prefectures or departments (*fu*), each containing an average population of 2,000,000; the prefectures into districts (*chai-'u*), and the districts into *hien* or sub-districts. The larger provinces are administered each by a governor general (*tsung-tu*) or viceroy, while of the lesser ones there is but one viceroy for two or three. Each province has besides a governor. At the head of the departments are intendants of circuit, at the head of the districts magistrates, and at the head of the *hien* petty officers who are charged with the enforcement of order, the collection of taxes, &c. Special imperial commissioners (*kin-chai*) are constantly sent to all parts of the empire to take a general surveillance. Governors general are appointed for three years; their powers are limited by those of a provincial cabinet, consisting of the governor, the military commandant, the provincial treasurer, and the chief justice of the province. According to the "Red Book" there are 8 governors general, 15 governors, 19 treasurers (2 in Kiangsu), 18 provincial chief justices, 17 literary chancellors, 15 military commandants, and 1,740 intendants or magistrates. The number of petty subordinate officers is immense. The whole forms the most stupendous bureaucracy in existence. The municipal government of Peking is a part of the general government. All public offices are open to those who have been successful in the literary examinations, without any distinction of birth, nationality, or creed. The salaries of all public officers are comparatively low, and hence corruption prevails among them. While governors general sometimes make millions of dollars in this way, even the pettiest subordinates may make their hundreds and thousands. Yeh, being questioned how much he paid to his secretaries, replied that their

salary was 100 taels (\$140) a month, but that they made three or four times as much by perquisites. The ordinary salary of a governor general is 20,000 taels, of a lieutenant governor 16,000, of a treasurer 9,000, of a provincial chief justice 6,000, of a military governor 4,000, of a general 2,400. The revenue of the central government cannot be ascertained by foreigners with any degree of accuracy, but it is much less than might be supposed. The estimates vary from \$180,000,000 to \$440,000,000, and even the latter amount would only be at the rate of a little over \$1 for every inhabitant. The taxes are partly paid in kind and partly in money, thousands of canal boats being constantly employed to carry the rice and grain collected from the farmers to Peking. According to Dr. Medhurst, \$42,327,954 land taxes in money, and \$12,692,871 in grain, are sent to Peking, while \$38,273,500 in money and \$105,689,707 in grain are kept in the provinces. This, with the revenue derived from customs and transit duties, which is set down by Dr. Medhurst at not over \$1,974,662, would give a total taxation of \$200,958,694. But there are other sources of revenue, such as the duties on salt, license money, stamp tax, government monopolies, mining, pearl fishery, the manufacture of gunpowder, &c. China has no public debt. Extraordinary sources of revenue, resorted to when necessity demands it, are sales of office and honors, temporary increase of duties, and contributions from the rich. The laws of China are collected into a general code (*Ta tsing liuh li*, i. e., statutes and rescripts of the great pure dynasty), and arranged under seven heads, viz.: general, civil, fiscal, ritual, military, and criminal, and those relating to public works. In theory this code might be considered as a sort of constitution of the empire, but in practice the high provincial officers frequently supersede it by issuing edicts upon matters that have been provided for already by law, or by reviving some old law, or by forced and arbitrary application of existing laws to special cases. The edicts are placarded in the cities and towns, and the more important ones circulated in pamphlet form. However excellent many of the written laws may be, their execution is by no means such as to give the people at large the benefit of them. Innumerable cases of judicial murder, extortion, and crime are reported in the Peking "Gazette," and the code recognizes cases of oppression and tyranny in which open rebellion of the subjects against the officers of the government would be justifiable. The cruelty of the tortures by which the magistrates sometimes seek to obtain confessions almost surpasses belief. The treatment of prisoners, who are caged like wild beasts, is barbarous in the extreme. Flogging (from 10 to 300 blows), transportation, perpetual banishment to remote provinces, slavery (hard labor), and death are the legal punishments of crime; im-

prisonment is regarded only as a corrective. Decapitation and strangling are the legal modes of executing criminals, the more cruel modes of quartering, flaying, starving to death, &c., having fallen out of use almost entirely. It is believed that the number of criminals who undergo the penalty of death is not one half of those who die from the effects of torture and imprisonment. The trials are held in public; they are brief and free of cost; no counsel is allowed to the criminal. Appeals to higher courts are frequently resorted to. Sentences of death require the signature of the emperor, but this form is dispensed with by a fiction of the presence of the emperor in every public office.—The military organization is very defective. As a general rule, the Chinese hate war, and do not consider superiority in military power an attribute of a higher order of civilization, though they esteem personal courage and praise their ancient heroes in songs and novels. "China owes her advance in numbers, industry, and wealth mainly to her peaceful character and policy." A standing army has existed since the 7th century. The soldiers in time of peace live in garrison in the large cities; they are poorly paid, and badly armed and equipped. There is nothing imposing about them except their numbers. The infantry carry matchlocks of the clumsiest kind, or spears, bows, swords, and bucklers; the cavalry, helmets, cuirasses of quilted and doubled cotton cloth, covered with iron plates or brass knobs, bows and arrows, and shields of strong wickerwork. The artillery have cannon of iron and brass of a heavy calibre, but scarcely know how to use them. The jingall, a kind of swivel resting on a tripod, is the most effective light arm the Chinese possess. Of late years the government has shown a disposition to adopt the weapons and the military methods of western states. In 1860-'61 Gen. Ward, an American, drilled a force of 2,500 Chinese after the foreign style. They were armed with foreign muskets, and dressed in a half-foreign costume. This organization was enlarged under Burgevine, another American, and Col. Gordon of the British army, and was very successful in expelling the Tai-ping troops from the province of Kiangsu. Some French officers drilled a similar force in the Chekiang province, and operated against the Tai-pings with like success. Arsenal, so called, have been established at Shanghai and Foochow. In each of these upward of 1,000 natives are employed under the supervision of foreigners. Firearms of all kinds are successfully made, and each establishment has built and launched four or five war vessels, some of them of nearly 3,000 tons burden. The want of courage of the Chinese soldiers has been proverbial, yet it is not without honorable exceptions. The Tartar garrison of the Pei-ho forts stood their ground with firmness in May, 1858; and there were many instances of daring exhibited by the native troops during the suc-

ceeding campaign. Gen. Ward used to say that he could take his disciplined corps where no white troops would go. It is likely that in case of another foreign war the Chinese government, having considerable supplies of improved arms and a knowledge of the foreign methods of warfare, would be able to make a much better contest than heretofore. A French officer, M. Giquel, in a recent book says that it would not be safe to undertake a contest with China with a smaller force than 40,000 men. The regular army, or the eight banners of Mantchoos, consists of 67,800, or, according to De Guignes, 100,000 Mantchoos, 21,000 Mongolian Tartars, and 27,000 Chinese. The pay of a foot soldier is from \$3 to \$4 a month, of a horseman about \$5. The green banner, or militia, numbers 700,000 men, mostly farmers and mechanics, wholly unfit for a serious conflict. Besides these, there are some irregular corps, bringing the total nominal figure of the army up to 1,230,000. Of so-called fortresses China has not less than 1,193, but only a few of them are built in a substantial manner and able to withstand a cannonade, while the rest consist merely of a common wall and ditch. The great wall (*wan-li-chang*, *i. e.*, the myriad-mile wall), on the N. frontier of China proper, is the most gigantic work of defence ever erected by man. It was originally built as a bulwark against the invasions of the Tartars (215 B. C.). It runs from a point on the coast of Liautung, lat. 40° 4' N., lon. 120° 2' E., in a westerly direction, to the Yellow river, in lat. 39½° N. and lon. 111½° E.; thence to lat. 37° N., and again in a N. W. direction to its termination in lon. 99° E. and lat. 40° N.; making 21 degrees of longitude, and with its windings a length of 1,250 or 1,500 m. In some places it is a simple rampart, in others a solid foundation of granite, while the eastern section has a height of from 15 to 30 ft., and a breadth such that six horsemen may ride abreast on it. There are brick towers upon it at different intervals about 40 ft. high. The navy has heretofore consisted of 1,951 war junks, entirely similar to trading vessels, and in no way able to withstand the means of modern maritime warfare. The whole number of vessels of the foreign style now (1873) in use as war vessels is about 20. These are placed under the control of provincial officers, and are supported from the several provincial treasuries. Foreigners have heretofore been employed to command these vessels, and to superintend their engines; but of late nearly all such have been dismissed. It is quite certain that they would in case of war fall into the hands of the enemy, and form a source of danger rather than of support to the government.—The history of China dates back nearly 5,000 years, but up to the year 2207 B. C. it bears a mythical character. The Chinese myths begin with the reign of the Tien-hwang, Ti-hwang, and Yin-hwang (the celestial, the terrestrial, and the human rulers). After them, Fuh-hi,

Great Wall of China.

who in the old legend appears also as a demigod, became the founder of the Chinese empire (2852). He is said to have taught the people cattle-raising and writing; to have introduced the divisions of the year, the institution of marriage, &c.; and to have died at the age of 200 years, after a reign of 115 or, as some accounts say, 164 years. His successor, Shin-nung, during a reign of 140 years, introduced agriculture and medical science. The next emperor, Hwang-ti, is believed to have invented weapons, wagons, ships, clocks, and musical instruments, and to have introduced coins, weights, and measures. His third successor, Ti-ku, established schools, and was the first to practise polygamy. In 2357 his son Yau ascended the throne, and it is from his reign that the regular historical records (*Shu-king*) begin. A great flood which occurred in his reign has been considered synchronous and identical with the Noachic deluge, and to Yau is ascribed the merit of having successfully battled against the waters. His reign lasted from 2357 to 2258, during which time he organized the political system of the country on a firm basis, fostered agriculture, industry, and commerce, built canals, roads, &c. His son and successor, Shun (2255-2207), ruled in the same spirit. So far, if the old traditions are to be relied upon, China enjoyed a golden age of national felicity. The beginning of the later history of China inaugurates a series of internal broils, revolutions, wars, and changes of dynasty. The immobility which is generally supposed to be the prominent characteristic of China does not appear in the history of her dynasties. The dynasty of Hsia (2207-1767) was founded by Yu the Great, who was the first to unite supreme ecclesiastical power to the temporal authority. His grandson was dethroned by a popular revolution in

favor of his brother Chung-kang, who held the reins of government with a vigorous hand. Shan-kang succeeded to the throne after a period of war, and by him and his son Ti-chu the country is said to have been well governed. Thereafter the dynasty degenerated until it was expelled by a popular movement, and replaced by the dynasty of Shang or Yin, which gave 28 rulers to the country (1766-1122), most of them vicious and cruel. The last one, Chowsin, terminated his miserable career in the same way as Sardanapalus. Wu-wang, the general who had succeeded in overthrowing him, became the founder of the dynasty of Chow and the regenerator of the empire. His dynasty ruled for a period of 873 years, the history of which is an almost uninterrupted catalogue of feuds, revolutions, wars with the Tartars, usurpations of princes and provincial governors. During the reign of Li-wang (571-544), the principal disciple and expounder of Confucius, Meng-tse (Mencius) was born. The dynasty of Tsin (249-202) restored the unity of the empire by resubjecting the vassal states which had obtained independence under the preceding weak rulers. Ching-wang (246-210) erected the great wall for the protection of the empire against the incursions of the Tartars, and assumed the title of *hwang* or emperor. Under the name of Tsin-chi hwang-ti, he is celebrated as the national hero of China. In order to destroy all traditions of the former political institutions, he decreed that all books treating of them should be burned. The writings of Confucius and Mencius were among them, a few fragments of which only could be found afterward. The dynasty of the Han (206 B. C. to A. D. 220) gave to the country the emperors Wen-ti (180 B. C.), the restorer of the ancient literature; Wu-ti (141), a great patron of

science and art; Siuen-ti (73), who subjected the Tartar country as far as the Caspian sea; Ming-ti (A. D. 58-76), under whose reign the Buddhist priest Ho-shung, from India, introduced the Buddhist creed, while the apostle Thomas is believed by the Armenian Christians to have been in China; and Ho-ti (89-106), who introduced the culture of the grape. About A. D. 200 a Roman embassy is said to have come to China. From 220 to 260 the empire was divided into three kingdoms, which were reunited by Wu-ti, the founder of the second dynasty of the Tsin (260-420). The Tartars, who had been kept in check by the former dynasty, now obtained a firm foothold in the northern portion of the empire, where they established an independent kingdom (386). Four dynasties (Sung, Tse, Liang, and Chin) ruled the southern empire till 590, a period replete with domestic wars, religious dissensions, and palace revolutions. In 590 the prince of Sui, having subjected the Tartar kingdom, conquered also the southern empire and reunited them. He was a wise ruler, a promoter of science, education, industry, and commerce. During the dynasty of the Tang (619-907) Christianity was preached by the Nestorian, Olopen (636). The emperor Kow-tsung extended his conquests to the boundaries of Persia. His son Tai-tsung was the Charlemagne or Haroun al-Rashid of China. His successors became abject tools of their eunuch courtiers (9th century), who were destroyed by Chow-tsung (890), but too late to save the dynasty. Once more the empire was torn by the feuds of contending dynasties, and the Tartars, whose relation to the Chinese empire was strikingly similar to that of the German tribes to the declining Roman empire, increased in power and importance. Tai-tsu, the founder of the dynasty of the Sung, and his successors (960-1279), under whose reign the arts and sciences flourished, were unable to keep the Tartars down. They were compelled to seek the aid of one tribe against another, but were in turn assailed by their allies, until the Mongolians overran the empire. Genghis Khan advanced on Peking in 1215. Kublai Khan (Chinese, *She-tsu*) established the first Mongol dynasty in China, having Peking as the capital city (1279-1368). The last emperor of the Sung dynasty drowned himself and family near Canton. The conquerors did not attempt to change the national customs and institutions, but favored Buddhism. Kublai conquered Cochin China and Tonquin. In his reign the European traveller Marco Polo came to China. In 1294 the first Roman Catholic missionaries appeared at Peking. In 1342 a famine having destroyed 13,000,000 people, a general revolution broke out. In 1358 a Buddhist monk of low birth, Chu Yuen-chang, assumed the lead of the revolution, overthrew the Mongolian dynasty, and ascended the throne under the name of Hung-wu. His dynasty (Ming) lasted 276 years (1368-1644), and gave to the country 16 rulers, most of them

efficient. About the middle of the 15th century the Tartars again invaded the empire, but were repelled. The invasions of the Mantchoos commenced under the reign of Shi-tsung (1522-1567). About the same time the Portuguese began to trade with the neighboring islands. In 1583 the Italian Jesuit Ricci was allowed to preach Christianity in China, and by conforming it in many respects with the traditions of Confucius he made many converts, even among the mandarins. In 1604 the Dutch sent three vessels to China, but were not admitted. When, in 1622, they tried to enter the empire by force, they were defeated; still they succeeded in establishing themselves on one of the Pescadore islands, which they afterward exchanged for Formosa. In 1615 the Mantchoos, exasperated in consequence of the assassination, by order of the Chinese emperor, of their king, had commenced hostilities, and when in 1635-44 the empire became again the theatre of bloody internecine wars, they took sides with the defeated imperial party against the insurgent usurper Li-tse-ching, defeated him, entered Peking, and proclaimed Shun-chi, the youthful son of their own king, emperor of China. He was the founder of the present Mantchoo dynasty, which has succeeded well in overcoming the strong national antipathies of the Chinese. In 1653 the Dutch were once more refused admission, while the Russians were allowed to trade with the northern portion of the empire. Shun-chi was educated by the German Jesuit Adam Schall, who, as president of the board of mathematicians, became in fact the prime minister. In 1661 Kang-hi succeeded to the throne. He conquered Formosa and Thibet, improved the financial condition of the government, promoted science and literature, established schools and colleges, had the different provinces of the empire surveyed and mapped by Europeans, and restored the Christian churches to the missionaries (1671). Two Frenchmen, Gerbillon and Bouvet, were his favorite advisers. During his reign the city of Peking was destroyed by an earthquake, when, according to native accounts, 400,000 perished among the ruins. Yung-ching (1722-1736) expelled the missionaries from the schools, in consequence of his suspicions of their designs and dislike of their overbearing conduct. His son Kien-lung (1736-1796) extended his dominion over the largest portion of central Asia. Although in general just and well meaning toward his subjects, he for a time persecuted the Christians, and turned a deaf ear to the requests of European powers (Russia excepted) to be admitted to commercial intercourse with China. His successor Kia-king (1796-1820), a voluptuous and cruel monarch, was unable to check the anarchy created by insurrectionary movements against his tyrannical rule. In 1807 Mr. Morrison, the first Protestant missionary, came to Canton, translated the Bible into Chinese, and in conjunction with Mr. Milne established the

Anglo-Chinese college at Malacca. In 1820 Tau-kwang ascended the throne (died Feb. 24, 1850). The most important event of his reign was the first war with Great Britain, known as the opium war. The British, having sent an unsuccessful commercial expedition against China as early as 1596, did not obtain a foothold in that country until the end of the 17th century. An embassy which they sent to Peking in 1793 under Lord Macartney was kindly received. The embassy of Lord Amherst in 1816 was not admitted into the presence of the emperor. The refusal was probably occasioned by Lord Amherst's unwillingness to perform the *kotow*, and did not result in any interference with the course of trade. Until 1834 commercial intercourse was conducted by the East India company. In that year their charter ended, and Lord Napier was sent out by the British government to superintend the trade. He endeavored to communicate with the viceroy at Canton by letter and on terms of equality. This was refused, and led to the bringing up as far as Whampoa (12 miles below Canton) of two frigates, which received and answered the fire of the forts at the Bogue (Sept. 11, 1834). On Sept. 21 Lord Napier retired to Macao, where he died three weeks later. After this trade was carried on without the immediate superintendence of the British officials till 1837 (April 12), when Capt. Elliot, the British commissioner, went to Canton under an agreement with the viceroy, which was a virtual abandonment of the position taken by Lord Napier, and acknowledgment of Chinese superiority. Capt. Elliot justified his action by a statement that the relations between the Chinese authorities and the merchants were in a precarious condition. This condition arose out of a discussion as to whether the trade in opium, which had been carried on in an illicit manner, should be legalized, and there was danger that the government would not only decide the question unfavorably, but take some active measures to put down the traffic. Such a decision was subsequently reached, and in the autumn of 1837 Capt. Elliot was directed by the viceroy to drive away the opium vessels, and to notify his government that they must not come again. The trade went on, however, under greater or less restrictions and difficulties, until the early part of the year 1839, when a special commissioner named Lin appeared with strenuous orders to thoroughly suppress it. One of his first steps was to demand the surrender of all opium. This order was complied with, and Lin was directed by his government to destroy it. The whole quantity, 20,291 chests, valued at about \$10,000,000, was placed in trenches, mixed with lime, and sea water admitted, a procedure by which the desired result was most perfectly accomplished. This measure did not however suppress the trade. More opium arrived and was sold clandestinely. In consequence of the continued irritation and

the persistent efforts of the commissioner to suppress the traffic, the British residents were withdrawn from Canton, and afterward from the Portuguese colony of Macao, and on Dec. 6 trade with the English was declared at an end. These circumstances led to the war of 1840-'42, known as the opium war. The British forces appeared off Macao June 22, 1840. On July 4 the island of Chusan, off the mouth of the Yangtse river, was occupied. Simultaneously the ports of Amoy and Ningpo, and the mouths of the Min and Yang-tse rivers were blockaded. The British plenipotentiaries proceeded toward Peking, and on Aug. 11 anchored off the mouth of the Pei-ho river. The Chinese officer Ki-shen met them there, and it was arranged that the discussion of matters at issue should be referred to Canton. Negotiations were continued at Canton as arranged for, and a treaty was effected. It was not ratified by the Chinese emperor, and on Feb. 19 hostilities were resumed, and the British fleet moved up to the city of Canton. On the 26th the Chinese paid a ransom of \$6,000,000, and the British prepared to leave their investing lines. The evacuation was very soon completed, and trade was reopened and continued throughout the war, which was prosecuted in the north. Amoy was captured on Aug. 27, Chusan was occupied a second time on Sept. 29, and Ningpo on Oct. 13. Desultory operations continued throughout the winter. In May, 1842, Chapoo was captured, and on June 16 and 19 Woosung and Shanghai respectively were occupied. In the latter part of July Chinkiang was invested and captured, and the forces moved to Nanking, 40 m. beyond Chinkiang. The native authorities, anticipating the loss of their ancient capital and thoroughly humbled by the events of the war, sued for peace, and a treaty was effected. This treaty provided for: 1, lasting peace between the two empires; 2, an indemnity from China of \$21,000,000 (\$12,000,000 being for expenses of the war, \$3,000,000 for debts due British subjects, and \$6,000,000 for the opium destroyed); 3, the ports of Canton, Amoy, Foo-chow, Ningpo, and Shanghai to be opened to trade; 4, Hong Kong to be ceded to the queen; 5, British prisoners to be unconditionally released; 6, Chinese who had been in British service to be held guiltless; 7, correspondence to be conducted on terms of equality; 8, the forces of Great Britain to occupy Chusan and Amoy until \$6,000,000 should be paid. On Feb. 24, 1844, Mr. Caleb Cushing arrived in China as commissioner of the United States, and without difficulty he negotiated a treaty which was signed July 3, 1844, at Wanghia near Canton. A treaty with France was signed Oct. 23.—The relations of foreign states with China moved along for several years with varying phases of friendliness and hostility. At the northern ports the people were generally friendly. At Canton, which had been spared from military occupation by

the British, and where the population is more turbulent than elsewhere along the coast, difficulties with foreigners were continually occurring. The great fact upon which the danger of the situation depended was that a satisfactory basis of intercourse had not been reached. Foreigners, coming as they did from states of advanced power and civilization, were unwilling to take up an inferior position before the Chinese. The emperor and his officials claimed for China the sovereignty of the world, and that it was by his august sufferance alone that intercourse was permitted. Many of the officials entertained a more or less just sense of the intelligence of foreigners and of the advantages to be derived from commerce; but Chinese officials are invariably time-servers, and they could not enter upon the task of enlightening the central government. At length it became manifest that a war would be needed to effect more satisfactory relations. The pretext for military operations was the seizure of the Arrow, a vessel of Chinese construction registered in Hong Kong under a colonial ordinance. On Oct. 8, 1856, a party of Chinese constabulary boarded this craft, tore down the British flag, and carried away the crew, who were Chinese. The British consul informed the viceroy of what had been done, and demanded the return of the men and a disavowal of the act of the constabulary. The viceroy returned the men, but refused to apologize. Further correspondence ensued, but a satisfactory result was not obtained, and the British authorities proceeded with such force as was available to active hostilities. It will appear strange to the reader that such operations should be entered upon by the British representatives without reference to the home government. It is to be remembered, however, that the Chinese government had persistently refused to receive on terms of equality the representatives of western states, and that the intercourse of foreign officials was carried on with the provincial authorities. There was no way to reach the imperial government excepting through these, and a petty war with them was the only recourse excepting a general war with the empire. During the preceding years since the establishment of relations at Nanking, these local operations had not been infrequent, and had resulted favorably as a rule without being carried further than a mere demonstration of force and of a determination to procure redress. The operations of the British forces at this time resulted in the capture of various forts near Canton. The viceroy, so far from yielding under this pressure, appeared disposed to defy British power, and proceeded to offer a reward for British heads, \$30 at first, and afterward \$100. An attempt to poison residents at Hong Kong followed. The running warfare thus opened was kept up for several months, the advantages resting with the Chinese rather than with the British. Meanwhile the situation was receiving the attention of the

government of Great Britain, and it determined to secure a satisfactory settlement, at the expense if necessary of a second war. The French government, actuated by a sense of the difficulty of conducting relations with China under the existing system, and having various grievances, concluded to join in an expedition intended to demand satisfaction and to enforce more satisfactory relations. The American and Russian governments held that they had no special ground for complaint, and, while sending out special ministers, gave them pacific instructions. It is a matter of history that the American envoy, who entered upon his mission with a disposition to deprecate the course of England and France, felt constrained at a later moment to admit that it was justified by all the circumstances, and that it would have been wiser for his country to unite in the effort to effect more satisfactory relations. An expeditionary force left England in the spring of 1857, but was diverted to India to aid in the suppression of the mutiny. Toward the end of the year a portion of the force reached Hong Kong, and Lord Elgin, with the support of Baron Gros, the French commissioner, was able to present an ultimatum to the viceroy. The response was deemed unsatisfactory. The bombardment of Canton by the allied British and French forces commenced Dec. 28, and the city was occupied the next day. The force engaged on the British side was about 5,000 men, the French 900. The combined losses were 10 killed and 100 wounded. The Chinese loss was perhaps 250. There was no lack of disposition to hold the city on the part of the Chinese, and many indications of valor on their part were shown. The speedy and comparatively bloodless capture of a city of more than a million inhabitants, in face of their best efforts to hold it, must be attributed simply to the superior organization, armament, and *morale* of the attacking forces. The viceroy Yeh was detained by the British authorities. The control of its inhabitants was necessarily confided to the native governor under the supervision of a commission of British and French officers. It has been mentioned in the notice of the war of 1840-42 that trade with Canton was continued while military operations were prosecuted in the north. So in this instance, the allies while holding Canton permitted trade to take its usual course. The several foreign representatives at this stage of proceedings met by arrangement at Shanghai, and united in a request to the government at Peking to send to that city a high commission with full powers to discuss the situation, and to effect more liberal treaties. Responses to these several letters were received in due course. The government, so far from acceding to the request for the appointment of a special commission, declared that Yeh had been degraded and that Hwang had been appointed in his stead, and enjoined the several envoys to repair to Canton. The latter

considered the response unsatisfactory, and determined to proceed toward Peking without delay. The advance of the combined fleet of the allies and of the Russians and Americans arrived off the Pei-ho about the middle of April, 1858, and soon afterward the envoys again despatched letters to the government requesting the appointment of a plenipotentiary. An answer was received to these notes indicating that certain officers had been named by the government; but as it did not appear that they possessed full powers, the envoys declined to communicate with them, and declared their intention to proceed toward the capital. After a delay of several weeks, the allies bombarded the forts at the mouth of the Pei-ho, and stormed them. The Chinese made no adequate resistance, and these strongholds were occupied with but few casualties. No time was lost in reaching Tientsin, 50 m. above the mouth of the river. Here the envoys were met in June by Kwei-liang and Hwa-shana, plenipotentiaries of the Chinese government. On the 14th the Russian treaty was signed, and on the 18th the American. The British treaty, much fuller in its scope, was signed on the 15th, just 15 years after the treaty of Nanking, and the French the next day. These latter treaties stipulated for the residence of ministers at Peking, for the opening of additional ports, for travel and trade under restrictions in the whole empire, for the navigation of the Yangtse river, and for the settlement of the transit-dues question. Four millions of taels (about \$5,500,000) indemnity was provided for in the British treaty, and a smaller sum in the French. The British envoy, taught by experience to anticipate evasions by the Chinese government, insisted upon the ratification of his treaty before leaving Tientsin, and received within a few days the imperial decree. It contained also the ratification of the other treaties. Treaties of amity and of commerce were thus concluded, but the very moment when elsewhere difficulties would have been at an end, was signalized by hostile conduct on the part of the native troops at Canton. So serious were these, and so peculiar were the relations of foreign states with China, that Lord Elgin did not hesitate to advise the British commander-in-chief to undertake at that point vigorous action, "showing our power to control and punish the braves." Mr. Bruce, afterward Sir Frederick Bruce, was appointed by the British government minister to China, and in the early part of the year 1859 proceeded on his mission. At Hong Kong he was met by a report that the imperial government was hostile to the treaty concluded by Lord Elgin, and was making warlike preparations at the mouth of the Pei-ho. At Shanghai he received letters from the imperial commissioner Kwei-liang and his associates urging him to remain in that city for the discussion of measures which they said had been left undetermined by Lord Elgin. Mr.

Bruce believed these representations were intended only to procure delays, and determined to proceed north in order to exchange the ratifications of the treaty. The French and American ministers were met by similar representations, and regarded them in the same way. On arriving off the mouth of the Pei-ho the river was found to be well fortified, and every incident corroborated the information received at Hong Kong that the emperor would not accede to the expectations of the envoys without pressure. On July 25 Mr. Bruce received a letter saying that the imperial commissioners had been recalled from Shanghai, and would be directed to accompany him to Peking. As some time would elapse before their arrival, he was requested to wait at the anchorage, and informed that the governor general would at the right moment go to his vessel and conduct him to the mouth of the Pehtang river, a small stream 10 m. N. of the Pei-ho, from whence he could proceed to Peking by land. The letter was considered unsatisfactory, as indicating an unusual and disagreeable route to the capital, and because the name of her majesty was not put on a level with that of the emperor. Thereupon Admiral Hope, in command of the British forces, attempted to force the passage of the Pei-ho, but was defeated with a considerable loss. The British and French ministers retired to Shanghai to await instructions. The American minister, Mr. Ward, whose treaty contained no essential clauses not embraced in Mr. Cushing's treaty of 1844, concluded to proceed by the route indicated by the Chinese. He disembarked with his suite at Pehtang on July 20, and was conducted in the rude carts of the country to the Pei-ho above Tientsin, thence in boats to Tungchow, 12 m. below Peking, and from that point to the capital in carts. He was here treated with a show of consideration, but was denied an interview with the emperor unless he should perform the *kotow*, and finally was obliged to exchange the ratifications at Pehtang. Mr. Ward on his return to Shanghai informed Mr. Bruce that he was "more convinced than ever of the soundness of his (Mr. Bruce's) determination to proceed to Tientsin under his own flag, and of the accuracy of the information as to the unreasonableness of the court and the influence gained by the anti-foreign party in the emperor's counsels." The British government received the information of the occurrences at the mouth of the Pei-ho in a spirit which must commend itself to every student of history, and to every one who has at heart the dignity and honor of the West in its relations with eastern exclusiveness and arrogance. Their minister was directed to demand a formal apology for the act of the Chinese troops at the mouth of the Pei-ho, to receive any friendly overtures thereafter in a conciliatory spirit, but to decline any ceremonial unless it should recognize the equality of his government; and he was at

the same time informed that the government would make such arrangements as might be necessary to enforce acceptance of the terms offered to the Chinese emperor. The French government received information of what had occurred in the same spirit, and entered upon similar preparations to enforce their views. The ultimata of the two governments were addressed to the Chinese government in March, 1860, and in April the response was received flatly refusing the demands of the allies. Lord Elgin and Baron Gros reached Shanghai in June as special ambassadors of their respective governments. The month of July was occupied with preparations for the approaching campaign. On Aug. 1 a force of 5,000 men was landed by the allies at Pehtang, which was found to be deserted. The Pei-ho forts were taken from the rear on the 21st, and Tientsin was occupied without resistance on the 24th. At this point imperial commissioners appeared, who declared that they had full powers and presented them. A negotiation ensued, which resulted in the preparation of a treaty; but at the last moment the commissioners stated that they could not stipulate that the convention would take effect without previous ratification. The ambassadors could only attribute this action of the commissioners to a design to create delay, and determined to march against the capital. While the allied forces were moving forward, other representations were received which led to further negotiation, and to an arrangement that the troops should halt at Tungchow, where conferences, which it was hoped would be final, should be held. Mr. Parkes and others were sent forward to this town to agree upon a place for an encampment, the means of procuring supplies, &c. While in the prosecution of their work they were arrested and detained under circumstances of indignity and cruelty. At the same moment the allied troops were met by indications of a determination to resist their progress, and a battle followed in which the Chinese were routed. The treacherous treatment of Mr. Parkes and his associates left the allies no alternative but to proceed against Peking, in front of which city they arrived on Oct. 6. Mr. Parkes and some others of those captured with him were finally given up on the 9th, but several Englishmen were killed by ill usage and horrible and protracted cruelty. One of the gates of the city was surrendered to the allies on the 13th. On the 24th a convention of peace, in terms nearly identical with that of the articles prepared a few weeks before at Tientsin, was signed, and the ratifications of the treaty of 1858 were exchanged. The next day a convention with France was signed, and the ratifications of the French treaty of 1858 were exchanged. An incident of this war which deserves mention is the destruction of the imperial summer palace. It has been condemned as an unnecessary and wanton act, and has drawn forth the severest stric-

tures in this country. The defence made by Lord Elgin is that the treatment of Mr. Parkes and his comrades deserved signal punishment, and that no other course would have so effectually humbled the government with so little harm to the people. Twenty-six British subjects carrying a flag of truce had been seized in defiance of honor and of the law of nations. Thirteen only were returned alive, all of whom bore marks of the indignities and ill treatment from which they had suffered; the others were barbarously murdered. The destruction of a palace was surely no undue retaliation for guilt so great. The death of the emperor occurred soon after the close of the war. The heir to the throne was under age, and a regency was established, which ended Feb. 23, 1873, by his assumption of power. During this interval the actual condition of the empire was greatly improved, and foreign relations were undisturbed. The more salient events were the suppression of the great rebellion, the close of the two Mohammedan rebellions, the despatch of the embassy of which Mr. Burlingame was the chief, and the Tientsin massacre.—The great rebellion, generally known as the Taiping rebellion, broke out in southern China in the year 1850. The British war of 1840–42 had destroyed the prestige of the imperial government. There had been repeated failures of crops in the districts where it originated, and such failures are frequently the cause of outbreaks in China. Hung Siu-tsuen became at an early moment the prominent figure in the outbreak. He had failed in the literary examinations, and was therefore unlikely to rise in the service of the government. He had read some of the tracts printed by the missionaries, and appears to have considered himself the recipient of divine messages. His associates professed to acknowledge a "supreme being" and an "elder brother." Foreigners were disposed to believe that they inclined toward Christianity, and that its cause would be advanced by their success. By April, 1851, the Taiping forces were well organized, and numbered upward of 12,000 men. A little later Hung Siu-tsuen assumed the title *tien-wang* or heavenly prince. They accomplished various successes in the provinces of Kwangtung, Kwangsi, and Hunan, and on Dec. 23, 1852, they captured Hanyang on the Yangtse. In January, 1853, they took Wuchang, the capital of the Hu provinces. In February Kiukiang and Nanking succumbed to their forces, and on March 8 they arrived before Nanking, which they captured on the 19th, murdering about 20,000 Mantchoos found in the city. In May a force was sent northward toward Peking. It consisted of only about 6,000 or 7,000 men, yet it marched over 400 m., subsisting on the country through which it passed. It was turned back when within 100 m. of the capital, and rejoined the forces at Nanking in the summer of 1854. For several years after the military operations

of the Taipings were little else than incursions to obtain contributions of money and provisions. The imperialists gradually closed in upon them, and at the end of 1859 their prospects were very gloomy. But in the spring of 1860 they attacked and routed the besieging army. The occupation of Chinkiang, Soochow, and the wealthy country lying between Shanghai and Ningpo, followed. The former city was threatened, but, being defended by foreigners, held out against the efforts of the insurgents. Ningpo fell into their hands. Had the Taipings displayed vigor and discretion, it is not impossible that they might yet have mastered the empire. But their government was one which built up not at all; it only ravaged the districts which it occupied, passing on to other districts when the first were exhausted. Unsatisfactory as had been the course of relations with the imperial government, foreign officials could not but feel that it represented law and order, and that its overthrow by the insurgents would be a disaster to native and foreign interests. Acting in accordance with this belief, the foreign governments determined to protect the ports open to trade. These became the bases of operations against the insurgents, in which the imperial armies were supplemented in some instances by detachments from the British and French forces, and by native troops drilled and commanded by foreign officers and armed with foreign weapons. Soochow and the other cities of the delta plain were reconquered in rapid succession, and in July, 1864, the Taiping capital succumbed. From thence a detachment of the insurgent troops found their way southward to the region where the rebellion had originated fourteen years before, and were dispersed.—Other important revolutionary movements were the Mohammedan rebellions in Yunnan and in the northwest, both of which originated in an attempt to extort from the government security against local oppressions. Notwithstanding a general massacre of the Mohammedans in Yunnan by the provincial authorities, the rebels gained strength, and in April, 1857, took Talifoo, the second city of the province, and in 1858 conquered the capital. Their leader, Tu-wen-si, assumed the title of Wen-soay (King or Sultan Suleiman), and succeeded in establishing his rule over an area of 65,000 sq. m. and a population of over 4,000,000. Only about a tenth of these were Mohammedans, who were called by the Chinese Kwei-tseu, but by themselves Pansi, which the English corrupted into Panthay. In 1866 the Chinese government agreed to recognize his independence, provided that he would make no further conquests, but he refused. In 1872 he sent his son Hassan to Europe to endeavor to establish friendly relations; but before any results were reached the Chinese took Talifoo and killed Suleiman. The conquest of the territory and the extinction of the empire of the Panthays followed.—The rebellion in the

northwest originated in 1862 at Singanfoo, capital of the province of Shensi, among the Mohammedan Dungenes, called by the Chinese Khoi-khoi or Khui-khui. It spread rapidly through the province of Kansuh and over the frontier of China proper into Dzungaria, and extended thence into E. Turkistan. Before the close of 1864 Khamil, Aksu, and Yarkand were taken, and soon after the Chinese evacuated the whole country. Dissensions broke out among the rebels, and an Uzbek chief, Yakub Kushbegi, gradually subjected the whole of E. Turkistan and part of Dzungaria, and established a government which still enjoyed independence at the end of 1873. In 1871 the Russians took possession of Kulja and the entire basin of the Ili. The territory thus lost by China embraces an area of about 600,000 sq. m., with 2,000,000 inhabitants.—The mission of Mr. Burlingame left Peking in the autumn of 1867. It had its origin in the desire of the government to demonstrate to western powers its friendliness, and to forestall demands of an extreme character which it anticipated would be made during the revision of the treaties of 1858 then about to take place. Its chief seized the opportunity to place before the world the indications of a marked change of policy on the part of the government, and to demonstrate that the old system of recourse to local authorities for the redress of grievances should be abandoned in favor of representation to the imperial authorities at Peking. The facts of his appointment to represent China, and of his being accredited to western states on terms of equality, afforded an indication of the marvellous change which had ensued since the war, and a more complete justification of the wisdom of the allies in insisting upon residence at the capital.—On June 24, 1870, a popular outbreak against foreigners occurred at Tientsin, resulting in a deplorable massacre. Its victims were the French consul, the vice consul, the interpreter of the French legation at Peking and his wife, a Catholic priest, nine sisters of charity, a French subject engaged in trade and his wife, and three Russians. The French consulate, the cathedral, and the missionary hospital in which the sisters were engaged, were destroyed. The most revolting barbarities were perpetrated before and after the deaths of the victims. The local officials cannot be held blameless for the massacre, but it has not been demonstrated that they intentionally promoted it, and the attempts made in some quarters to fasten responsibility for the event upon the government have been futile. The local officials were banished to a remote part of the empire, 15 of the rioters were executed, a large indemnity was paid for the destruction of property and for the families of those who had perished, and a special mission was sent to France to declare the regret of the government.

CHINA, Language and Literature of. I. THE COLLOQUIAL LANGUAGE. On the first access of Europeans to some knowledge of the lan-

guage of China, the most exaggerated notions were formed of its eccentricity and of the difficulty of its acquirement. A more intimate acquaintance, however, tended to dispel the illusion, and to show that much of the singularity that appeared to attach to it was really due to the fact that the written medium preserved the key to that agglutination or word-building, the traces of which in other languages disappeared before those who used them began to put their thoughts on record. It is true the language has very marked peculiarities, as the following observations will show; but these are merely a special phase of the universal development of human speech, arrested to some extent at an early stage by the use of a written character. The neglect of most writers on the language of China to distinguish clearly between the spoken and written forms, has resulted in the most confused notions entertained by those who are not familiar with the subject. That a close analogy exists between the oral and written media of communication cannot be denied; and yet it is equally true that their respective peculiarities are too distinctly marked to admit of the identification of one with the other. It is difficult indeed to believe that people ever spoke in the curt and sententious style of the books, and we have no evidence to prove a closer approximation of the two forms in any preceding age than we find at the present day. Be that as it may, it is easily demonstrable that in the oral medium as we now find it we have to do with a polysyllabic language. That a contrary view should ever have obtained, appears due to the confusion of ideas above referred to. It has been said, and not without a show of reason, that English is nearer a monosyllabic tongue than the Chinese. The fact that Chinese happens to be written in monosyllabic symbols does not really affect the question. English might be syllabically written with similar phonograms; and were these to a certain extent at the same time ideographic, the analogy would be perfect. The following sentence is taken at random from Thom's "Chinese Speaker": "When a man goes forth to take a walk, his com-pan-ions may be pulling and haul-ing at him." Merely separating the syllables in this manner shows the whole theory of Chinese monosyllabism. Now look at the Chinese equivalent of this sentence: *Jin chüh-lai tsöw-taou, päng-yew-mun lá-lá-chây-chây*. Here the groups connected by hyphens are as inseparable in sense as are those in the English version; and to dis sever one of the syllables of *päng-yew-mun*, for instance, would do as much violence to the sense as a similar operation on the corresponding English term com-pan-ions. In the various dialects there are many polysyllabic words for which there are absolutely no characters. The number of syllables in the language is, as might be expected, variously estimated by different authorities. Morrison, basing his system on that of the native dictionary *Woó chay yün fò*,

gives 411 simple vocables; but taking into consideration the varieties produced by the aspirates, they amount to 533; and by the further distinctions of the tones, the number is swelled to nearly 1,600. Premare, in his *Notitia Linguae Sinicae*, gives a list of 1,331 as the complete catalogue. Gützlaff estimates the whole number at 1,781. Mr. Wade, who has given uncommon attention to the subject for more than ten years, makes the whole number of simple and aspirated vocables in the Peking dialect 420, while by the application of tones the number is increased to 1,454. Probably the number of syllables in the Nanking and western Mandarin dialects may be somewhat in excess of this. The *Fun yün*, a native dictionary of the Canton dialect, gives the number of syllables when affected by the tones and aspirates as 1,582. Drs. Maclay and Baldwin, in their Foochow dictionary, which is based on the native work *Ts'èh lin pa yün ho ting*, a dictionary of the Foochow dialect, gives a list of 495 syllables that may be formed without aspirates or tones; but that is considerably more than the number in actual use. Even admitting that a perfectly accurate estimate could be made, it would doubtless be found that the numbers vary considerably for different parts of the empire. Mr. Edkins, who has given more attention to the sounds of the Chinese language than almost any one else, tells us that there has been a considerable secular transformation going on in the pronunciation from ancient to modern times; many relics of the older language being still preserved in the local dialects. The Mandarin or general dialect of China, which is that of the official class everywhere, is also the common language, with slight modifications, of several of the northern and western provinces. This is marked by the almost entire absence of consonantal terminations, *n*, *ng*, and *rh* being the only ones admitted. The provincial dialects of the south, however, have largely preserved the finals *k*, *m*, *p*, and *t*, and in one or other of them nearly all the letters of our alphabet may be found, either as initials or finals. It would be almost impossible to give even an approximation to the number of words in any of the dialects, made up with these syllables. In Stent's vocabulary of the Peking dialect, the most recent work of that class, the author says: "It does not contain all the combinations of characters, but a selection only of useful ones (amounting to upward of 20,000) sufficient for the use of beginners." It should be remarked, however, that while a large proportion of these are polysyllabic words, there are a great number of them also formed by combining two or more words.—No attempt having been made, even by foreign students, to reduce colloquial Chinese to an alphabetic system, the nearest approach has been to lay down two series of letters to represent the initials and finals, by which every syllable may be spelt. The following two lists, with one slight modification, are those adopted

by Medhurst in his Chinese dictionary, and are used throughout this article: 20 initials—*ch, ch', f, g, h, j, k, k', l, m, n, p, p', s, sh, t, t', ts, ts', y*; 55 finals—*a, ä, ae, an, ün, ang, äng, aou, ay, e, äa, äae, äang, äaou, äay, èè, èen, ei, èih, en, èö, eu, èuè, èuen, èüh, èun, èung, ew, èh, èn, ing, o, ö, oo, ow, üè, üen, üh, un, ung, wih, uy, wa, wä, wae, wan, wän, wang, wäng, wei, wo, wö, wüh, wuy, ze*. One of the most important elements in Chinese orthoëpy, and one upon which it is admitted to be most difficult to make one's self understood by a stranger, is the tones. These are certain modulations of the voice, which, applied to a vocable, determine respectively the different meanings of the word so spoken. The tones of the language have a history which shows a gradual change from ancient times to the present. According to Edkins, there was a time when the Chinese did not differ from other languages in the matter of tones. In the time of the Chow dynasty (12th to 3d century B. C.) there were but three, the even, long, and short, or 1st, 2d, and 4th of the present series. During the Han period (206 B. C. to A. D. 237) another tone began to make its appearance, the receding, or 3d of the category. At some period not earlier than the 10th century, the first was divided into an upper and lower, thus forming a 5th tone; and so was completed the system we find in use now in the midland and western Mandarin-speaking regions. The 1st or even tone is the musical monotone, neither admitting of inflection in the tone nor variation in the volume of voice. The 2d or long tone is that rising inflection which is heard in our own language, in every question that indicates some degree of surprise, and in the common expressions *ah! indeed!* The 3d or receding tone is a monotone like the even, with this difference, that it is an inverted swell, and dies away upon the ear like the tones of receding music. The 4th or short tone may be regarded as an abrupt monotone, like the *a* in the English word *rat*, omitting the final consonant. In Canton all the four tones are divided into upper and lower, forming eight in all. In the Shanghai dialect there are also eight. In Foochow there are theoretically eight tones, but practically only seven. In the neighborhood of Amoy there are seven; and in the Hakka dialect in Canton province there are only six. The most recent change among the tones is the abandonment of the short in the Peking dialect, where the words of that class are distributed among the other three classes, leaving only four tones now in that region. Gützlaff thus divides the syllables of the language among the four tones: 1st tone, 533; 2d, 501; 3d, 519; 4th, 221. Besides the aspirates and tones, accent is also to be taken into account, as modifying the utterance of a word; particular members of a sentence, according to the dialect, being subject to this modification.—Chinese possesses a grammar, in which all the parts of speech are nearly as well defined as in that of any other

language; but depending as it does so much on the value of position among the members of a sentence, it is less flexible than that of inflected tongues. Polysyllabic nouns are formed in various ways, among which are the following: 1. The combination of a root noun with a final particle, as *yin-tszè*, silver, where *yin* is the root and *tszè* the particle; *jih t'ow*, sun, where *jih* is the root and *t'ow* the particle. 2. Combination of a root noun with a personal suffix, as *chò jín*, master, composed of *chò*, master, and *jín*, man; *näng-foo*, agriculturist, from *näng*, farmer, and *foo*, person; *t'òo-hòò*, butcher, from *t'òo*, butcher, and *hòò*, resident; *müh-tsèäng*, carpenter, from *müh*, wood, and *tsèäng*, mechanic; *shwuy-shòw*, water-carrier, from *shwuy*, water, and *shòw*, hand. 3. Combination of a specific noun with a generic, as *pih-shòò*, the cypress, from *pih*, cypress, and *shòò*, tree; *lè-yá*, the carp, from *lè*, carp, and *yá*, fish; *tá-lè-shih*, marble, from *tá-lè*, the name of a place, and *shih*, stone. 4. Combination of a number with a root noun, giving a special meaning, as *szé-paòu*, writing materials, from *szé*, four, and *paòu*, precious objects (*i. e.*, ink, pallet, pencil, and paper); *pih-sing*, the people, from *pih*, a hundred, and *sing*, surnames. 5. Combination of two substantives of allied meaning, as *fung-süh*, custom; *é-sze*, meaning. 6. Combination of two antithetic roots, as *tung-se*, thing, from *tung*, east, and *se*, west; *tá-seaòu*, size, from *tá*, great, and *seaòu*, little. 7. Combination of two roots in construction, as *swán-fá*, arithmetic, from *swán*, calculation, and *fá*, laws of; *shoo-fáng*, library, from *shoo*, books, and *fáng*, room. 8. Combination of an adjective and a substantive, as *laòu-shòò*, rat, from *laòu*, old, and *shòò*, the genus *mus*; *lèäng-sin*, the conscience, from *lèäng*, good, and *sin*, heart. 9. Combinations of three, four, and more syllables are not uncommon, as *maè-máè-jín*, a trader, from *maè*, buying, *maè*, selling, and *jín*, man; *waè-kwò-jín*, foreigner, from *waè*, foreign, *kwò*, country, and *jín*, man. Adjectives are chiefly distinguished by the addition of the syllable *teih* to a qualifying root, as *haòu-teih*, good; *pih-teih*, white. Sometimes they are formed by the combination of two roots of allied meaning, as *lan-tó*, lazy, from *lan*, idle, and *tó*, indolent. Ordinal numbers are formed by prefixing *té* to the cardinal, as *san*, three, *té-san*, third. The personal pronouns are *wo*, I; *nè*, thou; *t'a*, he or she. The plural is formed by the addition of the syllable *mín*, as *wo-mín*, we. Verbs are formed by the combination of two or more syllables: 1. By a root and an auxiliary, as *nà-laè*, to bring, from *nà*, to take, and *laè*, come; *ké-tih*, to remember, from *ké*, to remember, and *tih*, obtain. 2. By two verb roots, as *hè-hwan*, to rejoice, from *hè*, to be pleased, and *hwan*, to be delighted. 3. By a verb and a noun root, as *shwò-hwá*, to talk, from *shwò*, to say, and *hwá*, words. Adverbs are formed in various ways, by the combination of two or more syllables, as *lè-mèen*, inside, *i. e.*, inner face; *waè-t'ow*,

outside, *i. e.*, outside head; *ch'a-p'uh-to*, nearly, *i. e.*, differ not much; *ts'ung-tse'n*, formerly, *i. e.*, from before; *man-man-teih*, slowly; *ch'ang-ch'ang-teih*, constantly; *ping-ping-gan-gan*, comfortably; *yih-tse*, altogether, *i. e.*, one arrangement; *yih-ting*, certainly, *i. e.*, one fixed. Prepositions are sometimes monosyllabic, sometimes dissyllabic, as *t'ang*, with; *ch'oh-leau*, besides. Postpositions are of very frequent occurrence, as *shang*, above; *heh*, below; *ts'ien*, before. Most of the conjunctions of other languages are found in Chinese. They are either disjunctive, as *huo-shé*, or; or adversative, as *jen-urh*, however; or causative, as *ke-jen*, since; or conditional, as *jo-shé*, if. Interjections are very numerous in Chinese: To express aversion, they say *pa-leau-pa-leau*; for sorrow, *k'ò-seih-leau*; for commiseration, *k'ò-t'ien*; for surprise, *ae-yá*, &c. In composition the adjective precedes the substantive, and the genitive precedes the nominative. The antecedent precedes the consequent; the verb is preceded by the subject and followed by the complement. The gender of persons is generally expressed by *nán*, male, and *neü*, female, followed by the syllable *jín*, person. For the lower animals *tsze* is used for the female and *heung* for the male. Sometimes also *kung* is used for the male and *mod* for the female. For persons, grammatical number is generally expressed by the plural affix, *mán*, but it is frequently indicated by some expression in the phrase. Such terms as *ching*, a multitude, *too*, all, *keae*, altogether, *tsuen*, the whole, and *to*, many, indicate the plural number, rendering any affix to the noun unnecessary. The genitive case is generally expressed by the affix *teih*; for the dative, *keih* is prefixed; the instrumental takes the prefix *pe*; for the ablative *tsung* is prefixed; for the vocative *o* is affixed; for the locative, *tsae* is prefixed. There are many other syllables used with the same powers. The moods and tenses of verbs are generally understood by the context. Sometimes for the present indicative *joó-kin*, now, may be introduced between the pronoun and the verb. An indication of former time, as *ná-shé*, at that time, will express the imperfect. The perfect may be expressed by the postfix *kó*, or *leau*, or *wán-leau*; the negative is formed by placing *muh-yew* before the verb. The pluperfect is formed by putting *è-king* before the verb and *kó* after it. A future is made by placing *ts'ang-laé* before the verb; *yaou* is also used. The second person of the imperative mood is made by affixing *pá* to the verb; the third person may be made by placing *yaou-ting* between the pronoun and verb. The optative is formed by preposing *pa-p'uh-t'ih* or *hán-p'uh-t'ih*. A negative imperative is made by placing *peé* before the verb. A salient feature in the language is the use of a class of words that are interposed between a number and the substantive with which it is connected, in the same manner as we use the word head in speaking of so many "head of cattle;" but

whereas this phraseology is rare and exceptional in English, it is on the contrary of almost universal occurrence in Chinese. It is difficult to render such terms literally into English; but, to take an example for the sake of illustration, a Chinese, instead of saying *yih-taou*, a knife, or one knife, would say *yih-pá-taou*, one handle knife, *pá* being used for most instruments held by a handle. Again, *san-t'eaou shay*, three serpents, *t'eaou* being generally applied to objects where length is the characteristic. *Chang* is applied to objects of the sheet kind, as paper, mats, &c.; *k'een* is applied to houses, *teang* to carriages, *wei* to persons, and *kó*, which is of most general application, is used with human beings and inanimate objects indefinitely. There are 20 or 30 such words in extensive use, and a much larger number of restricted application. By European writers they have been variously named, classifiers, numerals, distinctive numeral particles, numeratives, auxiliary substantives, &c.

II. THE BOOK LANGUAGE. A knowledge of colloquial Chinese is doubtless an important step toward understanding the written language, as theoretically and in the great leading features they are identical. Yet it is found that, even to a person well versed in one or more of the dialects, it is still necessary to make a special study before he can see his way through the native literature. Not only must he gain a familiarity with a considerable number of the characters, but the grammatical details have so much that is peculiar, that the application required is little if any less than what has been already spent in acquiring the spoken dialect. The more remarkable characteristics are conciseness of diction, the substitution of monosyllables for polysyllables, the employment of special particles, the absence of classifiers, and the more or less extensive use of stereotyped phraseology, consecrated by the usage of antiquity, and in many cases covering some recondite allusion, the resulting idea being such as nothing but the traditional explanation could unfold. The *Shao-wán* dictionary, which was completed early in the 2d century of our era, contains 9,353 different characters and 1,163 variants. This number has gone on increasing from age to age since that time, so that a recent edition of that work gives the number of characters in the language as 52,325; and even that number might be considerably increased were all the technical characters and variants included. Buddhism alone, we are told, has added 26,430, but most of these are confined to the works of that religion. The imperial dictionary of Kang-he, the most recent work of the class, gives 43,496; but when the obsolete forms and those to which no sound or meaning is attached are subtracted, the number remaining and in actual use is reduced to 32,873. It is not to be supposed, however, that the profoundest scholar is master of anything like this number; 10,000 or 12,000 would probably

suffice to make an accomplished graduate. An official historiographer under the Han dynasty was required to know 9,000 characters. In the "Canonical Four Books" there are altogether about 2,400, and with the five classics inclusive the number only amounts to about 4,600. With a ready command of 2,000 or 3,000 a person may assume a very respectable status in the literary scale. Gützlaff gives a computation of 24,235 as the number now in use.—Had we no historical data to guide us, an inspection of the structure of this vast mass of characters would naturally lead to the conclusion that they were not the result of a simultaneous effort; and it becomes a question of some interest to know by what incipient stages the system began to shape itself, and on what principle the gradual accretions have been going on from age to age. In reply to such questionings many of the natives have occupied themselves in the most profound researches regarding the characters; and according to the generally received theory, the whole system may be classed in six categories, *i. e.*, the *lüh shoo*, or six classes of characters. The first of these is called *l'èng-hing*, or hieroglyphs. These were termed *wán*, or figures, being the simplest forms, and were intended to represent visible objects, as ☉ *jih*, the sun; 👁 *müh*, eye; 口 *k'òu*, mouth. The earliest efforts of this kind are probably all lost sight of for many ages past; but the most ancient examples that have come down to us, in the grotesque figures on the bronzes of the Shang and Chow dynasties, give some faint resemblance to the objects they are intended to represent. The second class is termed *ch'è-szé*, or indicatives, and these show the first tendency toward the expression of abstract ideas, pointing to some property or condition; as 上 *sháng*, above; 下 *h'èu*, below; 三 *san*, three. In the third class, *h'wáy-é*, or composites, the first attempt appears to represent figurative ideas, by the combination of two or more hieroglyphs; as 明 *míng*, bright, formed by the combination of sun and moon. These were termed *tszé*, or derivatives, in contradistinction to the simpler *wán*, or figures. In the fourth class, called *heae-sh'ing*, or phonetics, we have a still further development of the graphic art, and the first approach toward an alphabetic symbolism. In this division one part of the character is hieroglyphic or ideographic, and the other merely represents the final sound, as in 江 *k'ang* and 河 *hó*, both signifying river. The same hieroglyph, 水 *shwuy*, or water, is the generic idea in both, and gives no clue to the sound; while in the first the accessory 工 *kung*, work, and in the second 可 *k'ò*, can, are simply phonetic elements, and add nothing to the meaning. The very inadequate resources of the three previous classes to supply the necessities of a moderately developed literature, may be seen in the fact that this class is

reputed to contain no fewer than 21,800. These four classes indeed include the whole of the written characters, and the two remaining divisions are merely special applications of already existing forms. The fifth class, called *ch'wèn-choó*, or defectives, includes characters which have come to be used for others of the same sound, as 說, used for 悅 *yuè*, pleased. The sixth class, called *k'èu-ts'èuy*, or substitutes, contains those characters which, besides the primary and obvious meaning, have acquired a secondary and metaphorical sense, as 長 *ch'ang*, long and a superior; 經 *king*, warp of a texture and classic. These classes, the tradition of which dates back to a considerable antiquity, are not always arranged in this order, which is adopted, with the explanations, from Twan Yüh-tsaè, one of the most erudite scholars of the present dynasty. Some authors, however, only make the first three classes to affect the forms of the characters, and the other three the sounds. Others again consider all the six classes as referring to the forms.—Apart from the elementary composition of the characters, there has been a great diversity in the modes of writing the same, from ancient to modern times. Some native authors enumerate as many as 36 different styles of writing; and the *Yü-ch'è-sh'ing king fóó*, an ode by the emperor K'een-lung, in praise of his ancestral city Mookden, is printed in 32 different forms of Chinese seal characters, and as many of the Mantchoo; but the greater part of these are fanciful or imaginary. Some seven or eight will include nearly all the styles that have been in general use. The invention of the earliest known, termed *koó-wán*, or ancient figures, is attributed to a sage named Tsang-hee; and under this term are included the semi-pictorial forms found on the ancient bells and vases. In the 8th or 9th century B. C. this was replaced by a different style, invented by one Chow-she, termed the *tá-ch'uen*, or greater seal character; and this in its turn gave way to the *seáu-ch'uen*, or lesser seal character, accredited to Le-sze, the minister of the famous Che-hwang of the Tsin dynasty (227 B. C.). In these two latter styles much of the pictorial had disappeared. The *Shwò-wán* is a dictionary of the lesser seal character. With the spread of literature, however, and the gradual adoption of silk for writing on in place of bamboo tablets, the seal characters with their curved lines were found to be too cumbersome. About the end of the same dynasty (206 B. C.), the *le-shoo* or official character was invented by Ching Mo. As the name implies, this was probably used in governmental documents; it is still sometimes employed for prefaces to books. The *h'ing-shoo* or running-hand is an elegant form of manuscript, especially suited to the hair pencil, which was already in general use at the time of its introduction during the Eastern Han dynasty (A. D. 56-220). The invention is as-

cribed to Lew Tih-shing. The *ts'au-shoo* or cursive character is an extremely abbreviated hand, much used in rough draughts and daily transactions. It was introduced about the same date as the preceding, by a scholar named Chang Pih-ying. The *k'uae-shoo* or typographic character is the square form generally used in books and printed documents, which was introduced about the 11th century. The three latter kinds are in general use at the present day. Great pains are taken by the Chinese to secure the correct and graceful form of their characters, and the most minute rules are laid down for their formation, both as to the order of sequence and proportions, which are carefully enforced by the teachers. All the characters in the language are reckoned to be made up of the eight elementary parts contained in the character 永 *yùng*, signifying eternal, *i. e.*, a dot, horizontal line, perpendicular line, hook, spike, sweep, stroke, and dash. There is a small native work containing 92 short rules for writing, illustrated by examples. These examples, with a partial translation, have been published by Davis, in the "Transactions of the Royal Asiatic Society," vol. i., under the title *Eugraphia Sinensis*.—Dictionaries of the characters are numerous, and, as may be supposed, it was necessary to adopt some artifice in the arrangement of these, in order that by a fixed method any character might be easily discovered in the mass. To effect this, a certain number of distinguishing characters were at an early age selected, to which all the others might be respectively referred. These are termed *pó* by the Chinese, which has been variously translated elements, keys, and radicals. The latter is probably the most convenient term. The number of these radicals has varied in different ages. The *Shuo-wán* has 540; the *Yüeh-p'ien*, completed in 523, has 542; the *Lü-y-p'ien*, by Sze-ma Kwang, has 544; in the *Lü-shoo p'ien é*, which appeared early in the Ming dynasty, the number of radicals is reduced to 360; in the *Ching yüan wuy p'ien*, published about the beginning of the 17th century, there are 239, and a supplementary class of characters at the end, not referable to any radicals; the *Tszé wuy*, which was published at a later period of the same dynasty, contains only 214; and the two principal dictionaries that have been published during the present dynasty, *Ching tszé t'ung* and *K'ang ho tszé t'ien* (which latter forms the basis of Medhurst's "Chinese and English Dictionary"), have both adopted the number fixed by the *Tszé wuy*. These are divided into 17 classes, according to the number of their strokes. In the 1st class are 6 radicals, each composed of a single stroke; the 2d class has 23 radicals of 2 strokes each; the 3d class has 31 of 3 strokes; 4th class, 35; 5th, 22; 6th, 29; 7th, 20; 8th, 9; 9th, 11; 10th, 8; 11th, 6; 12th, 4; 13th, 4; 14th, 2; 15th, 1; 16th, 2; 17th, 1. These for the

greater part represent elementary hieroglyphs, and are probably as judicious a selection as could have been made. Gonçalves has reduced the number of the radicals to 127 in his *Diccionario China-Portuguez*, but it is doubtful if his system will ever extend beyond the work in which it first appeared. Most of the radicals represent generic ideas, and have been classed by Kidd under the following 10 categories: 1st, celestial objects, as sun and moon; 2d, atmospheric phenomena, as wind and rain; 3d, human properties and relations, as head and father; 4th inferior animals, as tiger, bird, and fish; 5th, elements of nature, as fire and water; 6th, terrestrial productions, as wheat and rice; 7th, abstract qualities, as black and bitter; 8th, weapons and utensils, as lance and dish; 9th, verbs, as to walk and to follow; 10th, miscellaneous terms, as error and garments. Under one or other of these heads every character in the language is to be found, and in very many instances the radical gives the generic idea of the special character sought. The radicals do not hold any uniform position in the characters. Some are placed on the right side, some on the left, some at the top, some at the bottom, some in the middle, some on both sides, some surrounding the supplementary part, some embracing the top and right side, some the top and left side, some the left side and bottom, some at one of the corners, and a number of others promiscuously placed; all which must be learned from practice. Many of them are very much abbreviated and altered in form when used in composition, so as scarcely to bear any resemblance to the isolated figures. Under each radical in the dictionary, the related characters are arranged *seriatim*, according to the number of additional strokes; so that having discovered the radical and counted the number of extra strokes, it is in most cases a very simple process to pick out the character in question. There is a great difference in the number of characters attached to the various radicals. According to the *Tszé wuy*, which contains about 30,000 characters, the 140th radical, *ts'au*, herb, has 1,423 under it; the 85th, *shwü*, water, has 1,330; the 75th, *mü*, tree, has 1,230; the 64th, *shòu*, hand, has 1,012; the 30th, *k'òu*, mouth, the 61st, *sín*, heart, the 38th, *neü*, woman, all have large numbers connected with them; and so on through the whole list, the numbers gradually decreasing till we come to the 138th, *kán*, a limit, which has only 5 characters under it. The character having the greatest number of strokes is 靄 *ping*, the sound of thunder, the last under the 173d radical, 雨 *yü*, rain, being a quadruplicate form of 雷 *láy*, thunder. In some works of a higher class, pedantic authors are in the habit of using strange and obsolete forms, in place of the ordinary characters. In novels and books of light reading many of the characters are so much abbreviated that a special

practice is necessary to enable one to read them off with ease. In epistolary correspondence and other writings by the partially educated, it is a very common practice to replace the proper character by another of the same sound without regard to the meaning, thus moving unconsciously a step in advance toward phonetic writing. As it is a point of etiquette to refrain from mentioning the private name of an emperor, it has become customary to avoid writing the characters; and when one occurs, it is replaced by another of the same meaning. Thus the *T'ung-t'een*, a work of the Tang, speaking of the famous Buddhist traveler Fa-h'een, changes the last character *h'een*, meaning brightness, for the synonymous character *m'ing*, because *h'een* happened to be part of the private name of the emperor Chung-tsung. Sometimes the character is abridged by one or more strokes, as in the name of the Kin dynasty Tartars, who were formerly named Neu-chin; but the private name of the emperor Hing-tsung of the Leaou dynasty containing the character 眞 *chin*, the Chinese historians of the period omitted the two lower strokes, thus forming the character 直 *chih*, and they have retained the name of Neu-chih ever since. Sometimes the character is mutilated without changing the sound, as in the case of 寧 *Ning*, part of the private name of the emperor Taou-kwang, which is now commonly written 寧 *ning*, with the same sound and meaning. In more formal documents it is replaced by 甯, a homophonous synonyme. A curious illustration of the same practice is found in the *K'ang-he* dictionary. The character 玄 *heuen*, which formed part of the name of the reigning monarch, having been the 96th radical in the *Tszé wuy* and *Ching tszé t'ung* dictionaries, was promoted to the 95th place in the new dictionary, being the first in the five-stroke class. In common use, as in the name of the idol Heuen-te, it is often replaced by 元 *yuén*. The private name of Confucius was 丘 *Kew*, which in reading the Chinese avoid pronouncing, by saying *mow* ("such a character") instead. In like manner it is considered a mark of filial piety to refrain from writing the name of a parent; and some invariably omit one or two strokes when such characters occur.—The Chinese write in vertical columns, following from right to left, and it is customary in the better class of works to raise the name of the dynasty a character above the other columns; even should it occur anywhere in the middle of a column, that column is abruptly broken off, and the imperial character carried up to commence another, while the sense of the passage is continuous, as if there were no break. The title or functions of the emperor are raised two characters above the other columns, and the titles of the imperial ancestors are raised three characters. In inscriptions and docu-

ments, the mention of an emperor is frequently preceded by a blank of two characters' length, as may be seen in the famous Nestorian inscription at Se-gan. The Taiping rebels, in their proclamations, were accustomed to elevate the title of the heir apparent one character, the designation of Jesus Christ, and also the chief Hung Sew-tseuen, two characters, and that of God the Father three characters above the other columns.—The prevalence of monosyllables in the written language has been referred to. Thus, for the word silver, instead of *yin-tszé* of the colloquial, *yin* alone is used; for sun, instead of *jih-tow*, the syllable *jih* is used; instead of *choo-jin* for master, *choo* is used. For the verb *ké-t'ih*, to remember, *ke* is employed; and *hwan*, to rejoice, takes the place of *he-hwan* of the colloquial. Another peculiarity of the written language is the capability of some of the characters assuming the rôle of different parts of speech, according to the positions they occupy in a sentence. Thus the same character represents the verb *sh'ih*, to eat, and the noun *szé*, food; another represents *yó*, music, and *lò*, to delight in; *e* in the first tone signifies garments, while the same character pronounced in the third tone means to dress. In classical books we find a character undergoing an analogous change of meaning even without any alteration in the pronunciation; as *laou*, meaning old and to treat one as due to age; also *yew*, young and to treat one as due to youth. This peculiarity extends to other parts of speech also, as *e*, strange and to be astonished.—All the cases of nouns may be indicated by position, and the oblique cases also by certain particles. The genitive is preceded by *che*. The dative is preceded by *yu* or *hoo* following a verb. The accusative is preceded by *e*, *yu*, or *hoo*. The vocative is followed by *hoo*. The ablative is preceded by *yu*, *hoo*, *tsze*, or *tsung*. The locative is preceded by *yu*, or followed by *chung*, *nuy*, *k'een*, *che-chung*, *che-nuy*, or *che-k'een*. The instrumental is preceded by *e*. Moods and tenses of verbs are generally indicated by the general construction of a sentence, though particles also are sometimes used. Past time is indicated by the prepositions *ts'ang*, *chang*, *ke*, *king*, and *e*. Occasionally *ts'ang* is employed to mark the future. Pronouns are sparingly used, unless the sense or the rhythm actually requires them. The first person is often replaced by a term of humiliation, as *yu*, the stupid one; while a term of exaltation is used to replace the second person. When the pronoun *yu*, I, has to be written or printed, it is often put in smaller type than the other characters, as a mark of humility; just the reverse of our English practice. III. LITERATURE. It has been said that the Chinese have the most extensive literature of any nation in the world; and it is certain that in no other are the records so continuous and complete for a period ranging over 2,000 years. The very earliest fragments that have any claim to genuineness do not extend higher than the

first thousand years B. C., and it is not till the latter part of that period that we meet with any noticeable list of authors. The works of Confucius then come before us; also several of the great writers of the school of Taou, some famous moralists and writers on the military art. The mechanical appliances in aid of literature at that time, however, must have been sorely discouraging to authorship. Even several centuries subsequent to Confucius slips of bamboo were still used, on which the characters were scratched or engraved. These were gradually superseded by the silk texture, and in the beginning of the 2d century of our era paper was invented, the pencil having already been brought to a considerable degree of perfection. More than two centuries before Christ, history speaks of an effort made by the first monarch of the Tsin dynasty to destroy the great body of the existing literature, his decree exempting only writings on medicine, divination, husbandry, and the annals of his own house. The decree was supposed to be executed, and entailed at the same time the death of a great number of scholars. In 190 B. C. the law for the suppression of literary works was repealed by the emperor of the Han then reigning, and a stimulus was given to learning. The historian of the Western Han, which came to an end in A. D. 24, gives a catalogue of works in the imperial library, comprising classics, philosophy, poetry, military tactics, mathematics, and medicine, consisting of 11,292 sections, by more than 500 authors. Works were then written on scrolls, and continued to be so down to the 10th or 11th century, when printing came into general use, and the huge piles of manuscript rolls gradually dwindled down to the dimensions of a few antiquarian curiosities. It has frequently been asserted that there is nothing in Chinese books to repay the trouble of learning to decipher them; and in view of the protracted study necessary to acquire a competent familiarity with the subject, there is a certain amount of truth in the statement. It should, however, be noted that the books of the Chinese have not had fair play at the hands of Europeans; and too frequently it happens that, either from want of the requisite attainments on the part of the translator, or from a desire to hold up to ridicule a subject uncongenial to his taste, translations and quotations have been little better than caricatures. At the same time, it must be admitted that some translations have been very favorably received by western scholars, and give the earnest of much that may yet be discovered in this unexplored mine.—In taking a rapid review of the literary productions of the empire, it will be convenient mainly to follow the order and classification generally adopted by native writers, and to commence with what are termed the *King*, or "Classics," which are supposed to have been written by or to have passed under the revising hand of Confucius. These are held in the

highest reverence, and looked upon as the standard from which there is no appeal. They are five in number, and four of them at least, there is good reason to believe, passed through the hands of the sage in one form or another. One, the history of his native state, is said to be his own composition; but another, the "Book of Rites," appears in such a fragmentary state, that it is thought by critics to be a compilation by some scholar during the Han dynasty. The earliest of these, the *Yih-king*, is a veritable mystery. The nucleus of the work is a series of figures composed of whole and bisected lines. These were at first eight in number, and attributed to the legendary sage Füh-he, each consisting of three lines. Ranged in octagon form, these eight trigrams are very extensively used as decorative objects, on dishes, vases, bells, utensils, the lintels of doors, the gables of houses, the ceilings of rooms, and a numberless variety of other positions, being rated to comprise a vast amount of hidden wisdom. Their names are *k'een*, heaven; *t'uy*, vapor; *lé*, fire; *chin*, thunder; *sun*, wind; *k'an*, water; *k'an*, mountain; *kwän*, earth. These are variously looked upon, as the heads of categories, the rudiments of written language, or symbols of philosophic systems. By squaring the number, 64 were produced, each formed of two of the original trigrams, superposed one on the other, and each one having a separate name. These hexagrams, which are assigned to a later hand, form the themes of so many separate sections in this famous book. Wän-wang, the founder of the Chow dynasty, while in prison for a state offence, employed his time in studying these symbols, and appended a short text to each, under the name of *T'wan*. These are followed by remarks in detail on the several strokes of each hexagram, which are called *s'ang* (figure), and are said to have been added by Chow-kung, the son of Wän-wang. The additional portion of the work tradition ascribes to Confucius, being a kind of commentary, reflections, and apparently irrelevant remarks on the texts of Wän-wang and Chow-kung. Although more than 500 commentaries and treatises have been written to elucidate this strange book, it is scarcely saying too much to assert that none of them have succeeded in bringing an intelligible meaning out of it. If there be any meaning at all, it is probably a work on divination or some occult art. There is a Latin translation of the *Yih-king* by Père Regis and other Jesuit missionaries (edited by Julius Mohl, 2 vols., Stuttgart and Tübingen, 1834). The second classic, named the *Shoo-king*, contains a sketch of the ancient history of China, from the 24th century B. C. down to the emperor Ping-wang of the Chow dynasty, 721 B. C. It appears to have been compiled by Confucius, from the historical remains of the Yu, Hea, Shang, and Chow dynasties; but in the vicissitudes of the earlier ages it has evidently suffered much in its integrity. Tradition asserts that it con-

sisted of 100 chapters as it left the hand of Confucius, but nearly all the existing copies having been consigned to the flames by Che Hwang-te, the book burner, the now existing copies are the outcome of the mutilated fragments and half-suspected versions bequeathed to posterity by the first three or four centuries of the Christian era. Even in its imperfect state, however, it is a most interesting document, and apart from its historical character, and description of the great flood, it supplies more than hints regarding the principles of government, astronomy, music, agriculture, and other subjects of great importance to our knowledge of those ancient times. About 150 treatises, exegetical and illustrative, have been written about the *Shoo-king* as a whole or in particular portions. It has been translated into French by Gaubil (edited by De Guignes, Paris, 1770; also in Pauthier's *Livres sacrés de l'Orient*, 1841), and into English by W. H. Medhurst (Shanghai, 1846) and James Legge, D. D. (vol. iii. of "The Chinese Classics," Hong Kong, 1865). The third member of this pentateuch, the *She-king*, consists chiefly of a collection of ballads used by the people of the various petty states of China in ancient times, selected and arranged by Confucius, to the number of 311, of six of which, however, nothing but the name remains. The book is divided into four parts: 1, odes of the various states; 2, minor odes of the kingdom; 3, higher odes of the kingdom; 4, temple hymns. From these stanzas we get more insight into the life and manners of the people in the early ages than from any other work extant. They are simple in composition, frequently descriptive of rural and domestic life; many are martial odes, with covert political allusions, and hints at the prevailing state of society. Upon this also about 150 illustrative works have been written. It has been translated into Latin by Père Lacharme (edited by Mohl, Stuttgart and Tübingen, 1830), and into English by Dr. Legge (vol. iv. of "The Chinese Classics," Hong Kong, 1871). The evidence for the *Le-ke*, or "Book of Rites," seems less satisfactory than that for the others. Subsequent to the book burning merely scattered fragments of the original work were to be found, till Tae Tih, a scholar of the 1st century B. C., made a collection of miscellaneous pieces, to the number of 214 sections, only a small proportion of which, however, are believed to have belonged to the work of Confucius. He reduced the collection to 85 sections, which has since been known as the *Ta tue le*. This was revised by his nephew Tae Shing, who reduced the whole to 49 sections, in which form it has been called the *Seaou tue le*, and has been transmitted from age to age as the *Le-ke*, and by imperial authority ranks as one of the five classics, though secondary in grade. It is the most bulky of the whole, and is replete with lessons and rules for daily conduct, public and private, bearing throughout the theory that

true etiquette is but the manifestation of rectitude of heart. More than 70 works are to be found illustrative of this book. There is a French translation by Callery (Turin, 1853). The *Ch'un-ts'ew*, the last of the five, is the only one actually written by Confucius, being the history of Loo, his native state, from 722 to 484 B. C. As an incipient effort in the art of history making, it appears to have called forth much admiration and eulogium in early times; but, consisting as it does of a very bald detail of state occurrences, it can scarcely maintain a high position in the judgment of unbiassed critics. There are about 250 works illustrative of this text. (English, "The *Ch'un-ts'ew*, with the *Tso chuen*," vol. v. of "The Chinese Classics, by Legge.") Besides the special commentaries on the separate classics before referred to, there are about 80 exegetical works treating of all the five. In 1270 a work was published, called *Choo tsze yu luy*, in 140 books, consisting of the discourses of Choo He, as recorded by several of his disciples. From this Ching Chuen extracted and arranged the philosopher's elucidation of the five classics, which he published in 1725, under the title *Choo tsze woo king yu luy*, in 80 books. The name of Choo naturally gives much weight to this compilation. A sixth classic, under the title *Yö-king*, or "Book of Music," is spoken of in ancient times as also the work of Confucius; but it is now lost, and the only vestiges on the subject extant are a section in the *Chow-le* and another in the *Le-ke*.—During the T'ang dynasty a compilation was made under the name of the *Shih san king*, or "Thirteen Classics." In this collection three of the commentaries on the *Ch'un-ts'ew* were also admitted to the rank of secondary classics. Of these, the most important and best known is the *Tso-chuen*, by a scholar named Tso, supposed to have been a disciple of the sage. This is a narrative of events contemporaneous with the *Ch'un-ts'ew*, but so fully developed, and so much superior to the latter, that it has been said, "In no ancient history of any country have we such a vivid picture of any lengthened period of its annals, as we have from Tso of the 270 years he has embraced in this work." The other two commentaries, named after their respective authors *Kung-yang chuen* and *Küh väang chuen*, are much less known and read than that of Tso. The substance of both was handed down orally for centuries, but that of Kung-yang was put into writing about the beginning of the Han dynasty, and the *Küh väang chuen* more than a century later. They consist chiefly of scholia and expositions of the text of the classic. A number of works have been written in elucidation of these three commentaries. Besides the "Book of Rites" above noticed, there are two other works of the same order, reckoned among the secondary classics. The *Chow-le*, or "Ritual of the Chow Dynasty," claims a very high antiquity, and has been at various times repudiated, and again accepted

as genuine. The evidence now seems to be in its favor. It contains a full account of the government organization during the Chow dynasty, giving a catalogue of the officers with the functions of each. It is divided into six sections, entitled respectively by the names of heaven, earth, and the four seasons, the last of which, the winter section, was never recovered after the burning of the books, and has been supplied by another ancient document, called the *K'aou kung ke*, or "Artificer's Record." In the *Chow-le* is found the type of the present six administrative boards at Peking. About 60 works have been written in reference to this book. (French by Biot, Paris, 1851; English by Gingell, "The Ceremonial Usages of the Chinese, B. C. 1121," London, 1852.) The *E-le* appears also to be of very remote origin. The subject matter consists of rites of a more private and domestic character. The book is now little studied or read, although there are about 40 works on record treating it in detail. The *Sze-shoo*, or "Four Books" *par excellence*, having long held their place as secondary classics, are now far better known and incomparably more read than any of those above mentioned, being the class books of the schools all over the empire. Foreigners frequently designate them the "Canonical Four Books." The first of these, named the *Tu-hëo*, originally formed part of the *Le-ke*, but was separated from it by Choo He, who arranged the collection as it now stands. It consists of 11 chapters, the first of which is called the classic text, being the words of Confucius on the fundamental principles of ruling a kingdom, which he traces to the source of personal self-government. The remaining 10 chapters are by his disciple Tsang Ts'an, amplifying by quotations from history the sententious text of the sage. Several versions of the *Tu-hëo* have been published, generally in collections: in Latin, by Ignatius a Costa (with the Chinese text, Keen-chang-foo, 1662; without, Paris, 1687); in English, by Morrison (London, 1812), by Marshman (with the Chinese and a praxis, Serampore, 1814), and by Legge (in "The Life and Teachings of Confucius," London, 1869); and in French, by Pauthier (Paris, 1837). The *Chung-yung* is the work of Tsze-sze, the grandson of the sage, and is the most profoundly philosophic of the four. It treats of the moving principles of human action, and illustrates the practice of virtue by an ideal perfect man. When all the passions and affections are held in perfect equilibrium, the heart is said to be correct. Besides other editions and translations, the *Chung-yung* has been published by Rémusat in Chinese and Mantchoo, with Latin and French versions (Paris, 1817); and in English by Legge (London, 1869). The *Lun-yu* consists of a collection of pithy sayings and detached dialogues between Confucius and his disciples and others; apparently reminiscences of the sage and his teachings. There is much

in the doctrines laid down calculated to fortify men in the practice of virtue, and we even find the golden rule of Christ expressed by Confucius more than once, though in a negative form. There are some things in it, however, sanctioned by this great teacher, to which a Christian cannot assent. There is a Latin translation in *Confucius Sinarum Philosophus* (Paris, 1687); German, in Schott's collection (Halle, 1826); English, by Marshman (first half, Serampore, 1809), and by Legge (London, 1869). The fourth of the "Four Books" is known by the title of *Mäng-tsze*, that being the name of the author, which in European works is Latinized into Mencius. He is said to have been a pupil of a disciple of Tsze-sze, the author of the *Chung-yung*, and flourished during the 4th century B. C. He had much intercourse with the princes and grandees of his time, and appears to have been lively in his character and ready-witted in conversation, ever ready to frown down oppression and tyranny by cutting sarcasm and well-timed parables. His work, which is larger than the three others put together, contains a record of his sayings and dialogues with various characters with whom he had come in contact; the main object of his teaching being to commend the practice of benevolence and integrity. He takes occasion also to aim his shafts at several of the heresiarchs of his time. Although, like many other philosophers in that age, he had a numerous company of disciples, he does not appear to have occupied that high position in the mind of his contemporaries which subsequent generations have accorded him. His work is said to have escaped the general burning, as being considered extra-classical; and it was not for several centuries that it was promoted to the honored rank it now holds. The Chinese text, with a Latin translation by Julien, was published at Paris in 1824. It has been translated into English by Legge (Hong Kong, 1861). There are 170 or more exegetical works on the "Four Books," and by far the most popular is Choo He's commentary, which is read in the national college of Peking. There is a Latin version of the whole, together with the *Heaou-king* and the *Seaou-heo*, by Noel (Prague, 1711; translated into French by Pluquet, Paris, 1784). The "Four Books" have been translated into English by Collie (Malacca, 1828), and into French by Pauthier (Paris, 1841). The *Heaou-king* is a tract extolling the virtue of filial piety and inculcating its practice, and is reckoned one of the secondary classics. It professes to be a conversation between Confucius and his disciple Tsang Ts'an, recorded by another disciple. Grave doubts are entertained as to its authenticity by many scholars. They say neither the style nor the doctrine is in keeping with its pretensions. Thirty or more exegetical works have been written on it. Besides the Latin and French translations before mentioned, there is a French one in *Mémoires concernant les Chinois* (Paris, 1779), and an English one by

Bridgman in the "Chinese Repository" (Canton, 1836). The *Urh-ya*, the last of the thirteen classics, is a kind of dictionary of terms used in the classical and other writings of the early ages. Tradition ascribes the authorship to Tsze-hea, the disciple of Confucius, and the nucleus of it is even said to have come down from Chow-kung, regent of the empire in the beginning of the Chow dynasty. The work is divided into 19 sections, according to subjects, as—1, Ancient Terms; 2, Words; 3, Phrases; 4, Kindred Relations; 5, Houses; 6, Utensils, &c.; each term being found with a brief explanation in its own special category. The oldest commentary, by Ko Po, a scholar of the 4th century, is generally published with the text. Other works have been written on the *Urh-ya*, but none of equal reputation with this. This is the type of a class of works which, though admitted as appendages to the classic division, are yet put in the lowest grade. Another work of some reputation, arranged on the same principle as the *Urh-ya*, is the *Lüh shoo koo*, written about the close of the Sung dynasty. Although there are many cyclopaedias arranged on this principle, there are comparatively few works that we should call dictionaries. A more general plan is to arrange the characters under a fixed number of radicals. Several of the best known lexicons on this plan have been already mentioned. The Chinese were first initiated into the science of analyzing sounds by the Hindoo missionaries in the 5th century, and the *Yüeh p'ien* is the earliest extant work in which we have the system of syllabic spelling applied. This system consists in the employment of two characters to represent the pronunciation of a third, the exponent characters being followed by ㄅ *ts'èè*, implying bisection. The initial of the first exponent is then to be prefixed to the final, including the tone of the second. The result is the sound of the character required. From that time began the practice of indicating the sounds of characters in the dictionaries. A third class of dictionaries is those in which the characters are arranged throughout according to the sounds; a certain number of symbols being selected as finals, to which all others with the same finals respectively are referred. These dictionaries are first divided into four parts, corresponding to the four tones, and subservient to these is the arrangement of the finals. The earliest of this class extant is the *T'ang-yun*, a production of the 8th century, with a system of 206 finals. The *Ts'èè yun che chang t'oo*, a small work by the historian Sze-ma Kwang, is the first of this class in which the Hindoo system was adopted. He employs 36 initials, under which are arranged, according to the four tones, 3,130 characters. The *Le poo yun l'èè* was issued under imperial patronage in the 11th century, to rectify the disorders that were creeping into the rhymes at the examinations. The original copy had only 9,590 characters,

but in an augmented edition subsequently published the number amounted to 13,647. The *Woo yin tseih yun*, which appeared about the end of the 12th century, contains 53,524 characters, and reduces the number of finals to 160, under each of which the characters are referred in order to the 36 initials. In the 13th century, Lew Yuen of Ping-shwuy again reduced the number of finals to 107, and his system with slight variations has continued in use to the present time. The *Hung woo ching yun*, which was published under the immediate patronage of the first emperor of the Ming dynasty, reduces the number of finals to 76. Although this work is well known, it never came into general use. About the commencement of the present dynasty, Koo Yen-woo, a scholar of great talent and acquirements, wrote several small works of this class. P'wan Luy, one of his pupils, was the author of the *Luy-yin*. In this he makes a selection of 147 finals, and increases the number of initials to 50. He treats largely of the modern changes in pronunciation. The *Woo chay yun suy*, published in 1592, is arranged according to the 106 finals. The *Yin yun ching go* is a concise work of modern date, arranged according to 65 finals. The *Woo chay yun foo*, published early in the 18th century, has 36 initials and 128 newly selected finals. The *Woo fang yuen yin*, a dictionary of the Mandarin dialect, published in 1710, has 12 initials and 20 finals. The *Pei wän yun foo*, compiled under the special superintendence of the emperor and published in 1711, is arranged according to 106 finals distributed among five tones. It is usually bound in 110 thick volumes, and is probably the most extensive lexicon ever published. The quotations from preceding works are extremely numerous and complete, far exceeding anything of the kind that had been done before. Works of this class are very numerous, and much more used by students than the radical division.—In the number and extent of their histories the Chinese stand unrivalled. Their dynastic history alone is a marvel. During the Sung dynasty the "Seventeen Histories," including so many dynasties, were published in a single work. Under the Ming a corresponding work was issued, with the title of the "Twenty-one Histories;" and during the present dynasty the "Twenty-two Histories" and "Twenty-four Histories" have successively appeared. These are the work of nearly as many authors, the history of each dynasty being generally written in the period of its successor, with all the advantages of access to the national archives; and several of the authors stand high in the literary scale. The last named collection, beginning with the *She ke*, and ending with the *Ming she*, or "History of the Ming dynasty," numbers in all 3,264 books or sections, and averages probably two or three of these books to a volume. The whole are written on a generally uniform plan, though each differs somewhat in detail, and there is much diversity

in the style of execution; Pan Koo's *Ts'een han shoo*, or "Book of the Former Han," for instance, being looked up to as a model, while scholars are lavish of their censures on the historian of the Sung. As a rule, each history is divided into three sections: 1, "Imperial Records," containing a succinct chronicle of the several reigns of the dynasty; 2, "Memoirs," consisting of a succession of articles on astronomy, rites, music, jurisprudence, political economy, state sacrifices, uranography, meteorology, geography, and literature, giving the state of these various subjects during the dynasty; 3, "Narratives," in which are included biographies of all persons of eminence, and short historical statements regarding foreign countries. The *She ke*, by Sze-ma Ts'een, in 130 books, the first of the series, is much praised for its style, and is exceptional in its arrangement. Commencing with the mythical period of Hwang-te, it reaches down to the emperor Woo-te of the Western Han. A great part of the materials had been collected by Sze-ma T'an, the father of the author. It is divided into five sections: 1, imperial records; 2, chronological tables; 3, eight treatises on rites, music, harmony, chronology, uranography, sacrificial service, watercourses, and weights and measures; 4, genealogical history of the princes; 5, narratives of persons and countries. Much of the original work is lost. There are double histories, the old and the new, of the Tang dynasty, and also of the five dynasties succeeding, both of which are admitted into the standard collections. The new histories of both these are by Gow-yang Sew, a scholar of established reputation early in the Sung. In the *Sin woo tae she*, or "New History of the Five Dynasties," he has departed somewhat from the beaten track, both as to style and arrangement. He omits the memoirs altogether, and divides his work into five sections: 1, imperial records; 2, narratives; 3, researches; 4, genealogical registers; 5, appendix. It was printed by orders from the emperor, after the author's death. Another class of histories may be termed annals, giving the consecutive run of events as a whole chronologically arranged. The *Ch'un ts'ew* of Confucius is undoubtedly the earliest example of this kind; and the next in pretension is the *Ch'uh shoo ke n'een*, or "Bamboo Annals," which we are told was found in the tomb of one of the Wei princes, A. D. 284, supposed to have been there for several centuries. The record, which was on slips of bamboo, began with the fabulous reign of Hwang-te, and extended to 299 B. C. It is the general conviction that the original text has been long lost, and that the book now bearing that name is a fabrication. There are some things however that favor a belief in its genuineness. (French by Biot, Paris, 1842; English by Legge, Hong Kong, 1865.) The records of several of the dynasties have been written separately in this fashion, but the most celebrated production is the great

work of Sze-ma Kwang, entitled *Tsze che t'ung keen*, on which he was engaged for 19 years, in the latter part of the 11th century. This, with the various appendices, comprising 326 books, embraces a period from the commencement of the 4th century B. C. down to the end of the five dynasties preceding the Sung. A prefix to this history, entitled *T'ung keen wae ke*, in 10 books, was composed by Lew Shoo, the associate of Sze-ma Kwang; beginning with the myths of the fabulous period of F'uh-he, it ends at the place where the *T'ung keen* begins. About a century after the time of Sze-ma Kwang, the *T'ung keen kang m'uh*, which is a reconstruction and condensation of the *T'ung keen*, was drawn up under the direction of the celebrated Choo He. The first book only, on the principles of the work, is from the hand of Choo himself, the remainder being compiled by his pupils under his guidance. The whole is compressed into 59 books. An elucidation of this was afterward published by Yin K'e-sin in 59 books. Lew Yew also wrote a treatise on the principles adopted in the composition, in 50 books, on which he was occupied for 30 years. Wang K'ih-k'wan, in the early part of the 14th century, wrote an examination of the discrepancies connected with Choo's work. During the Yuen dynasty, Wang Yew-h'ö published his researches on the *T'ung keen kang m'uh*. In 1359 Seu Chaou-w'än completed a critical examination of the same. Early in the Ming, Ch'in Tsie published his correction of errors, being the result of a minute investigation of the *Kang-m'uh*. In 1465 Fung Che-shoo published his illustrations of the *Kang-m'uh* drawn from other sources. About the close of the 15th century, Hwang Chung-chaou dissected these last mentioned seven works, placing each paragraph under the corresponding part of the *Kang-m'uh*, when the work assumed the form it has retained to the present day, a very valuable compendium of history, the result of a vast amount of erudition. There is a French translation by De Mailla (*Histoire générale de la Chine*, 13 vols., Paris, 1777-'85). During the Sung, Kin Le-ts'ëang wrote an additional section, carrying the history back to the time of the monarch sage Yaou, and from that down to 431 B. C., where Choo's work commences. A further portion was afterward composed by Ch'in King, extending back to the fabulous era of F'uh-he. These two last portions were combined into one by Nan H'een in the Ming dynasty. In accordance with an imperial rescript issued in 1476, a supplement to Choo's history was composed by a committee of 15 scholars. Near the close of the Ming, these several sections were revised and published as a single work, by Ch'in Jin-seih, the national historiographer. It was divided into three parts, known respectively as the introductory, principal, and supplementary sections. Having been again revised and submitted for imperial inspection, it received the imprimatur in 1708,

and a new edition was issued in 91 books, under the title *Yu p'ei t'ung k'ien kang m'uh*. The *Fung-chow kang k'ien tseuen pien* is an abbreviated history in 32 books, by Wang Fung-chow, and embraces the period from Füh-he down to the end of the Ming dynasty. Morrison drew his historical information from this work, when composing his "View of China for Philological Purposes" (Macao, 1817). The *Kang k'ien e che üh*, by Woo Shing-keuen, is an abridgment of the *T'ung k'ien kang m'uh*, from the commencement of history to the close of the Ming dynasty. A considerable portion of this work, from the time of the monarch Yaou to B. C. 722, has been translated by Medhurst, and printed as an appendix to his *Shooking*. In this class of books, every year, besides being headed by the year of the monarch's reign, or some portion of his reign with a special designation, is also marked by two characters of the sexagenary cycle, thus providing a double check against error in the chronology. This cycle is formed by the combination in pairs of two series of characters, one numbering 10 and the other 12. In the most ancient works the cycle of 60 is never used for the years, but only for the days. In the dynastic histories it is used for both the years and days. In the *Kang-m'uh* it is very sparingly employed for the days.—A third class of histories may be designated "complete records," deviating as they do from the formal divisions of the dynastic histories, and paying little regard to the restraints of mere chronological technicalities. Dealing with every historical event *per se*, they bring all kinds of incident and information to bear on the matter in hand, regardless of contemporary questions which have no immediate bearing upon it. The histories of several of the dynasties have been written on this plan; but one of the principal works of the kind is the *Yüeh she*, a chronicle by Ma Süh of the present dynasty, in 160 books. The subjects treated extend from the creation down to 206 B. C. The *T'ung che* is a historical work belonging to still another class, which has been termed "separate histories." The plan is very much the same as that of the dynastic histories, but they are not limited as to the stretch of time they embrace, whether it include a great number of dynasties or merely one. The work just named is a history of the empire from Füh-he down to the Tang dynasty. The division of the work is into imperial records, biographies of empresses, registers, compendiums, and narratives. Matters of much interest are found in the compendiums. It was composed in the Sung dynasty by Ch'ing Tseou, and is in 200 books. The *T'ung t'ien* is a work not unlike the preceding in character, though some native writers place it in a different class. It also consists of 200 books, and was composed by Too Yew, a scholar of the Tang. It is divided into eight sections, on political economy, literary graduation, government offices, rites, music, military discipline, geography, and na-

tional defences. It extends from the earliest period of history to the middle of the 8th century, and is a work highly esteemed by the Chinese. The *Wän h'ien t'ung k'aou*, by Ma Twan-lin of the Sung, is a work well known to European scholars, from the frequent quotations and extracts made by sinologues. It consists of 348 books, which include a period from the commencement of history to the early part of the 13th century, very near the author's time. He has expanded the eight sections of the *T'ung t'ien* into 19, and added five more, on bibliography, imperial lineage, appointments, uranography, and phenomena. It has been wrongly named a cyclopædia by Europeans. These three works are looked upon as a set by the natives, who call them the *San t'ien*, or "Three Canons." A supplement to Ma Twan-lin's work was completed by Wang K'e in 1586, consisting of 254 books, bringing it down nearly to the end of the Ming. This continuation was revised by imperial commission, and an order issued in 1767 for the composition of analogous supplements to the *T'ung t'ien* and *T'ung che*, which were completed, bringing the whole down to the close of the Ming. A second supplement to all the three was also executed by imperial commission, extending the details to the 18th century. These contain a great fund of valuable and interesting matter, but unfortunately the text is very full of typographical errors.—There is a class called "Miscellaneous Histories," as a specimen of which may be mentioned the *Nam keang yüeh she*, a work in 30 books, composed about the end of the last century, under imperial patronage. The subject is the unsuccessful efforts of the last three descendants of the Ming family, Füh-wang, Tang-wang, and Yung-ming-wang, to reestablish the falling dynasty. It contains records of the princes and biographies. Many eventful episodes find a place in this class.—Biographies, including autobiographies, personal adventures, and travels, form a very numerous and interesting class, and extend over the whole range of Chinese history from several centuries before the Christian era. The *Kaou sze chuen*, composed about the 4th century, contains the biographies of 96 scholars. The *T'ang tsae tsze chuen*, the work of a foreigner from the west during the Yuen dynasty, contains the biographies of 397 authors and authoresses during the T'ang and succeeding five dynasties. The *Mwan chow ming chin chuen* is an imperial work in 48 books, containing biographical memoirs of all the famous Mantchoo ministers up to the middle of the last century. There is a similar record of the Chinese ministers of the present dynasty, entitled *Han ming chin chuen*. The *Koo t'è neu chuen* is a biography of famous women, written by Lew Heang in the 1st century B. C. There are a great many female biographies published at various times. The *Ta tsze gän sze san tsang jü sze chuen* is a history of the life and travels of the famous Buddhist priest Heuen-chwang,

but the book is very rare. (French by Julien, Paris, 1853.) The *Se she ke* is a short but interesting sketch of the progress of the Mongol army under the conqueror Hulagu, through central Asia, as far as Bagdad, from the year 1252 to 1259. The narrative is given by Ch'ang Tih, an envoy from the camp to the Tartar court at Karakorum. This has been frequently reprinted, sometimes in a separate brochure, and sometimes forming part of a collection. (French by Rémusat, Paris, 1829; and by Pauthier, 1865.) The *E yih lüh* is an account of an embassy through Siberia and Russia to the Tartar settlements on the Volga. (English by Staunton, London, 1821.) The *Tsing hae fun ke* is a narrative of the adventures of a notorious pirate fleet in the China seas. (English by Slade, in the "Canton Register," 1829; and by Neumann, London, 1831.) The *Ch'ou jin chuen*, a biography of philosophers in 46 books, appeared in 1799, from the pen of the well known scholar Yuen Yuen, formerly governor of Canton. Recently a supplement of six books has been added. Besides memoirs of all the celebrated men of science in China, the last three books form an appendix, treating altogether of foreign astronomers and mathematicians; among whom are found Meton, Aristarchus, Euclid, Clavius, Newton, and Cassini; and the Jesuit missionaries Ricci, Ursis, Aleni, Longobardi, Diaz, Terence, Rho, Schall, Verbiest, Stumpf, Smogolenski, Kögler, Pereyra, &c. There are also a number of Buddhist biographies, some giving an account of the Indian founders and luminaries of the faith, as the *Che yüè lüh*; and others recording the lives of those who have attained distinction in China in the same body, as the *Kaou säng chuen*, and the supplement to the same. When it is remembered also that more than half of the dynastic histories are occupied with personal memoirs, it may be imagined how much reading of this kind is included in the national literature.—"Historical Excerpts" also form a distinct class, and although it includes some tolerably voluminous works, they are not so numerous as most of the other classes. As an example may be noticed the *She wei*, in 330 books, published early in the present dynasty, consisting of choice extracts from the national history. As the term *king* was above explained to mean originally the warp of cloth, and metaphorically classic literature, so here the word *wei*, which is the counterpart of *king*, means originally the woof, and in its metaphorical sense implies the equal necessity of this to complete the great web of history.—"Contemporary Records" as a class includes the histories of various states holding an independent status beside the central government of China. Such is the *Shih lüh kwò ch'un ts'ew*, a history of 16 dynasties that existed contemporaneously with the Tsin and Sung. The names of these states are the Former Chow, After Chow, Former Yen, Former Tsin, After Yen, After Tsin, Southern Yen, Hea, Former Leang, Shuh, After

Leang, Western Tsin, Southern Leang, Western Leang, Northern Leang, and Northern Yen. The original work of this name, in 102 books, written about the 5th or 6th century, is lost; and the present work, composed during the Ming, is one of the most ingenious literary frauds on record. The *Gan nan che löö*, in 19 books, is an account of Anam, by a native of that country who sought refuge in China after having surrendered a city to the Mongol troops in the reign of Kublai Khan. A small class consists of "Chronicles of the Seasons," such as the *Suy she kwang ke*, a work of the Sung, detailing the natural indications of the months throughout the year, with the particular duties attaching to each.—Geography is a very voluminous class, if we include topographical works in the designation. The *Shan hae king*, or "Classic of Hills and Seas," is a small work full of monstrosities, and only claims notice on account of its great antiquity, as it is thought by some competent critics to be at least as old as the Chow dynasty. The *Ta ts'ing yih t'ung che*, in 500 books, is a carefully compiled geography of the empire, comprising an amazing amount of statistical information. The general plan of the work is to describe in succession the several provinces of the empire, noting the astrological division, limits, configuration of the country, officers, population, taxes, and renowned statesmen belonging to each. Under each prefecture and department there is a more detailed description of the various districts, descending to additional particulars regarding the cities, educational institutes, hills and rivers, antiquities, passes, bridges, defences, famous tombs, temples, men of note, travellers, remarkable women, religious devotees, and productions of the soil. A considerable section at the end is devoted to a description of the extra-frontier dependencies and foreign nations. This in itself is a huge work, but it sinks into insignificance when compared with the mass of topographical writings, which number thousands of volumes. For each of the 18 provinces there is a *T'ung che*, or "Provincial Topography," which may be considered a greatly amplified development of the headings in the last named work. As an example take the *Chè keang t'ung che*, or "Topography of Chekiang Province," in 72 books, which, although scarcely above half the size of some of them, is considered a very favorable specimen as to the general plan and execution. In this province there are 11 *foo* or prefectures, each of which has its *foo che*, or prefectural topography. Take as one of these the *Ning-po foo che*, or "Topography of Ningpo Prefecture," the first edition of which appeared in 1730, in 36 books. In this prefecture are 6 *heën*, or districts, to each of which there is a *heën che*, or district topography; as for instance the *Yin heën che*, or "Topography of Yin District," in 30 books. These are by no means the most voluminous of the series, and when it is remembered that there are 267 prefectures and 1,473

districts in the empire, and that each of these with rare exceptions has its record, some idea of this mass of detailed minutia may be formed. But even this does not include the whole; for there is a very extensive series also of similar accounts of famous hills, lakes, rivers, and places of note, such as the Bohea hills, Pootoo island, Silver island, the Western lake at Hangehow, and others far too numerous to refer to. There are many accounts of neighboring countries also; as the *Ch'au seën che*, a description of Corea written by a native of that country. The *Chin lä fung t'oo ke* is a description of Cambodia, written by a member of a Chinese embassy to that country in 1295-'7, and is now the only authentic account in any language of the state of that country in the ancient days of its prosperity. (French by Rémusat, with a map, in *Nouvelles annales des voyages*, vol. iii.; without the map, in *Nouveaux mélanges asiatiques*, 1829.) The *Wei tsang t'oo shih* is an account of Thibet. (French by Klapproth, Paris, 1831.) The *Hae taou yih che* is an account of Java and the Malayan archipelago. (English by Medhurst, "The Chinaman Abroad," Shanghai, 1849.) The *Se tsang ke* is a record of the country and customs of Thibet, with an itinerary at the end. There are a number of interesting accounts of central Asia by Chinese Buddhist travellers in different ages. The *Füh kwö ke* contains an account of the travels of the priest Fä-hên through Turkistan and India in the 5th century, where he went to investigate the state of Buddhism. (French by Rémusat, Paris, 1836; new ed., with illustrations, in Charton's collection, 1862.) In the *Lö yang kea lan ke*, a description of the temples in Loyang, the metropolis of the Northern Wei dynasty, is a similar account of a mission of Buddhist priests in the 6th century. (German by Neumann, Berlin, 1833.) The *Ta t'ang se yih ke* is an account of 138 kingdoms of central Asia, translated chiefly from the Sanskrit, by Heuen-chwang, a Chinese priest who had travelled through most of these countries, during an absence of 16 years from his native land. (French by Julien, 2 vols., Paris, 1857.) The geography of Commissioner Lin, *Hae kwö t'oo che*, in 50 books, is a description of the world, first issued in 1844. The latest edition is enlarged to 100 books. A later production, the *Ying hwan che löö*, by Seu Ke-yu, formerly governor of Fo-kien, and now (1873) holding a high official post in the capital, though less bulky, is on the whole a much better account of the nations of the world. The maps, though very sparsely filled with names, are correct in the general outlines. The *Kwang yu ke*, a geography of the empire in 24 books, written about the commencement of the 17th century, is very useful as giving the ancient names of places at different periods.—A small number of books have been classed together as "Official Repertories," treating of the numbers and duties of various classes of officers of the empire, such as the *Leih tae chih kwan peau*, in 63

books, which consists of a series of tables of the officers of the several departments of government, and the changes that have taken place in the names and duties of the respective offices, from the earliest times to the present dynasty.—"Works on the Constitution" comprise some very formidable productions; as the most voluminous of which may be named the *Ta ts'ing hway t'een*, in 80 books, giving a development of the general principles of the government under the present dynasty. There is an accompanying section of illustrative plates in 132 books; and a very imposing supplementary section in 920 books, consisting of a historical detail of the changes that have taken place in the several departments of the government since the commencement of the dynasty. Separate works also exist on the governmental regulations of each of the six supreme boards, and also of several of the subsidiary ones. A code of laws of the empire is published in 47 books, with the title *Ta ts'ing leüh le*, a book remarkable for the clearness of its phraseology, the reasonableness of its stipulations, and the general consistency of its ordinances throughout. (English by Staunton, London, 1810; French by Sainte-Croix, Paris, 1812.)—"Catalogues," under which head are included books on inscriptions, are also tolerably numerous. The catalogue of the *Sze koo tseuen shoo* library, with the historical and critical information appended to each title, forms one of the finest specimens of bibliography possessed by any nation. The *Wän yuen kö shoo müh* is a catalogue of the imperial library of the Ming dynasty. It was republished in 1800 in 20 books, a bare list of titles. The *Wüh gan leih swan shoo müh* is a catalogue of the mathematical and astronomical works written by Mei Wüh-gan, compiled by himself, containing much curious information on the state of the science in China. The *Kin shoo müh lüh* is an *index expurgatorius*, in two parts, the first containing works of which parts only are objectionable and forbidden; the second consists of books that are condemned *in toto*. There are several ten thousands of volumes in all, chiefly written about the close of the last dynasty, and nearly all of a political tendency. Other lists are in circulation comprising a long array of novels and light reading, forbidden in consequence of their licentious tendency. The most complete work on inscriptions is the *Kin shih tsuy peën*, in 160 books, a comprehensive collection from nearly 2,000 before Christ to the beginning of the 13th century of our era. The texts are given *in extenso*, and much critical addenda.—Although native scholars altogether exclude novels from a place in their literature, yet they are in fact a very important and influential class of reading, forming as they do the views and opinions of the large mass of the people on the history of their own country, being almost the only source from which they gather any ideas on the subject at all. They are not so numerous, however, as might be expected under the

circumstances; nor do they to their readers lose any of their freshness with age. They are more or less colloquial in language, and are studied by foreigners as exercises in the Mandarin dialect. From one and another a tolerably connected view of history may be obtained. In the *Fung shin yen e* we have the adventures of Woo-wang, son of the founder of the Chow dynasty, about the 12th century B. C. The *Lêe kwò che* embraces the last five or six centuries of the same dynasty. The *Se han yen e* covers the first two centuries B. C., being the story of the Western Han popularized; and the *Tung han yen e*, which is a corresponding tale of the Eastern Han, includes the first two centuries of our era. The universally read and most popular story of the *San-kwò che yen e* turns altogether on the troubles that followed on the overthrow of the Eastern Han, when the country was divided into three states, embracing the period from 168 to 265. (French translation of the first 44 chapters, by Pavié, 2 vols., Paris, 1845.) The *Nan yih chaou yen e* describes the succeeding period, when the empire was divided between the northern and southern dynasties. The *Suy tang yen e* is a popular record of the Suy and Tang dynasties. The *Tseen t'ang* relates the downfall of the Tang dynasty. The *T'ang woo tae chuen* gives the latter part of the Tang with the succeeding five dynasties. The *Shouy hoo chuen* is a tale of brigandage about the close of the 11th century; and the *Shwò yò tseuen chuen* is founded on the history of Yò Fei, a famous general of the 12th century. The *Se yew ke* is a mythical account of the adventures of Heuen-chwang, the Buddhist priest who went to India in search of Buddhist books in the 7th century. The *Kin ping mei* is a picture of the dissolute manners of the age at the beginning of the 12th century. As a literary work it stands high, but is condemned for its immoral character. The *Se yang ke* is an apocryphal history of the expedition of the eunuch Ching Ho to subdue the refractory nations of the southern ocean, at the commencement of the 15th century. The *Ching tih huang yew keang nan chuen* recounts the adventures of the emperor in a supposed incognito journey through Kiang-nan province in the 16th century. (English by Tsin-shen, Malacca, 1846.) Life in the metropolis during the present dynasty is depicted in the *Hung low mung*, written in a very colloquial dialect. The *Haou kew chuen* ("The two Fair Cousins") is a tale of social life. (English by Percy, London, 1761; French, Lyons, 1766; German by Marr, Leipsic, 1766.) The *Yüh keaou le* is also a picture of domestic manners. (French by Rémusat, Paris, 1826; by Julien, 1864; English, London, 1827.) The *Ping shan lang yen* is more admired for the language than the plot. (French by Julien, *Les deux jeunes filles lettrées*, Paris, 1860.) The *Leaou chae che e* is a popular book of fairy tales, or rather stories of elfin foxes and such like, by P'oo Sung-ling,

and published by his grandson in 1740. There are in all 300 of these legends, collected by the author chiefly from the mouths of the people, among whom there is a strong belief in the possession of foxes by these ethereal sprites. The *Kin koo ke kwan* is a small collection, as the name implies, of marvellous tales of fiction relating to ancient and modern times. The *Lung'oo kung yan* is a series of *causes célèbres* in the Chinese courts of justice, giving a curious insight into some of the more tortuous cases of jurisprudence among them.—In contrast with the preceding, there is a class of authors termed orthodox writers, who are deemed the special upholders of the doctrine of Confucius, and whose works are assumed to be the proper objects of study for all who aspire to eminence in the government or the school of the literati. Every age has had its men of mark in this school, and, comparing the writings of various authors, we find considerable latitude of views among them. Before the Christian era we have such names as Seun Hwang, the opponent of the views of Mencius regarding the original rectitude of human nature, whose writings are known by the title *Seun tse*; Kea E, the author of the *Sin shoo*; Lew Heang, author of the *Sin seu* and *Shwò yuen*; and Yang Heung, author of the *Fü yen* and other works. It would be easy to go on from age to age, quoting such scholars as Han Wän-kung, Lin Shin-sze, and a host of others; but the period that calls for special notice is the 11th century, which forms an epoch in the history of the orthodox school. The philosophic views first propounded by Chow Leen-ke were followed up by Chang Ming-taou and the two brothers Ch'ing Haou and Ch'ing E. The renowned philosopher of China, Choo He, was the pupil of Ch'ing Haou, and by his writings gave a lustre to that school of teaching, that has been able to bear down all opposition. These men thought out for themselves a system of the universe, and formed a theory according to which all nature was developed by a process of evolution from a primal monad, or even something beyond that. The writings of Choo on natural and ethical philosophy have had a wonderful influence over the native mind. In 1713 the emperor ordered a collection to be made of the principal of Choo's philosophical works, which were published under his immediate supervision, with the title *Choo tse tseuen shoo*. One of his most widely popular productions is a small work for the instruction of youth, entitled *Seaou hëö*. (Latin by Noel, Prague, 1711; French by Pluquet, Paris, 1784; the first two out of six books in English by Bridgman, in the "Chinese Repository," Canton, 1837-'8.) It was one of Choo's pupils, Ch'in Chun, who first introduced the term *Sing le* as the designation for mental philosophy, and a number of works have been since written on that science. The third emperor of the Ming had a collection made of all the principal writings

on this subject, embracing the productions of 120 scholars, which was published in 1415, with the title *Sing le ta tseuen shoo*, in 70 books. This was revised by an imperial commission in the last century, and compressed into 12 books, with the title *Sing le tsing e*. Several of the monarchs of the present dynasty, as preceptors of the people, have written hortative and didactic works, enforcing Confucian ethics. In 1655 a treatise of this kind, under the title *King sin lüh*, was issued by the first emperor. It is divided into seven parts, and directed against heart vices. The *Shing yu kwang heun*, or "Homilies on the Sacred Edict," consists of 16 maxims by Shing-tsoo, the second emperor of the present dynasty. A short homily was added to each of these by the succeeding emperor in 1724, and orders were issued to have one of these read and explained to the people of every district, on the 1st and 15th of each month. (English by Milne, London, 1817.) Several elementary school books may be mentioned as belonging to this class, small in size, but widely known and read. The *San tse king* or "Trimetrical Classic," is a tract written in columns of three characters each, the subject matter including the elements of history, morals, and relative duties. Of this and the next there are several translations in English, French, and German. The *Tseên tse wän*, or "Thousand-Character Classic," is a small work consisting of 1,000 different characters, said to have been thrown together promiscuously, from which the author formed this rhyme, in lines of four characters each, in a single night. (Latin by Hoffmann, Leyden, 1840.) These two tracts form the preliminary studies of the school room, and are memorized by the scholars. Another little book which is in very common use is the *Yew hëö she*, or "Odes for Children." (English by Bridgman, in the "Chinese Repository," Canton, 1836.) The *Pih kea sing* is a mere catalogue of 454 of the family names of China, and is one of the elementary school books.—Works on agriculture form an important though not a very numerous class. Under this head native writers include the art of grazing, breeding cattle, rearing silkworms, and a variety of collateral branches of industrial science. A famous work of this kind is the *Nung ching tseuen shoo*, a cyclopædia of agriculture, as it has been termed, in 60 books. It is the production of Seu Kwang-ke, an early disciple of the Jesuits in the 17th century, better known to Europeans by the name of Paul Seu. After a series of pertinent quotations from the classics, he treats of the division of land, processes of husbandry, hydraulics, including European methods, agricultural implements, rearing silkworms, planting trees, breeding stock, manufacture of food, and provision against dearth. A still more comprehensive work was compiled by imperial order in 1742, with the title *Show she t'ung Kaou*.—Medical treatises are exceedingly numerous and various in their subjects. Medi-

cal practice in China, it is true, stands very low in comparison with European science; yet, considering the attention that has been given to the subject for 2,000 years, it is scarcely reasonable to condemn *in toto* their medical literature till we know something more about it. The medical art is divided by them into nine branches, relating respectively to the main arteries and blood vessels, their ramifications, fevers, female complaints, cutaneous complaints, cases of acupuncture, eye complaints, throat, mouth, and teeth complaints, and bone diseases. Each of these departments has its literature, while there are also very many works of a general character. The *Tung e paou keen*, a large work of Korean origin, embraces the whole compass of medicine, and has been several times republished in China. Books of prescriptions are very numerous. Materia medica has also received a considerable share of attention, as may be seen by the large work of Le She-chin, the *Pun ts'au kang müh*, in 52 books, on which the author was engaged for 30 years, having made extracts from upward of 800 preceding authors. It is in fact a kind of natural history, embracing the three kingdoms of nature, the subjects being arranged under the several divisions of water, fire, earth, minerals, herbs, grain, vegetables, fruit, trees, garments, and utensils; insects, fishes, crustacea, birds, beasts, and man. It was written toward the end of the Ming, and several editions have been published during the present dynasty. The nucleus of the work is traditionally ascribed to the half-mythical Shin-nung.—Works on astronomy and mathematics, though tolerably numerous, have a somewhat limited circle of readers, yet these are among the *élite* of Chinese intellects. The oldest work on this subject is the *Chow pe swan king*, a tract on the elements of trigonometrical observation and the rudiments of astronomy. It is thought to be a relic of the Chow dynasty. (French by Biot, Paris, 1842.) The *Sin e seang fä yaou* was written by Soo Sung at the close of the 11th century. The author had constructed a large celestial globe, with machinery to represent the mechanism of the heavens and illustrate the seasons, the whole set in motion by water power. The work named was written specially to explain the theory of these movements. The *K'ih seang sin shoo*, by Chaou Yew-k'in, appeared during the Yuen dynasty, and differed in several particulars from the orthodox views of the time. It ascribes the length of the day, not to the distance of the sun, but its altitude, and the heat of the atmosphere to the accumulation of air. The planets are made to circulate round the earth in parallels of declination, while they revolve round the pole of the ecliptic in tortuous paths. It ascribes the apparent increase in the size of the sun near the horizon to its nearer approach to the earth than when in the zenith. In other matters also it deviates from the received doctrines. On the arrival of the Jesuit astron-

mers in the 17th century, a great revolution took place in the native theories; the result of which was the compilation of the *Sin fā swan shoo*, in 100 books, about the year 1634, by an imperial commission consisting of natives and Europeans. It is divided into 11 parts, treating respectively of the elements of the system, standard numbers, calculations, instruments, general operations, sun's course, fixed stars, moon's path, nodes and conjunctions of sun and moon, five planets, and nodes and conjunctions of the five planets. The Ptolemaic theory is still adhered to, but Tycho Brahe's discovery of the variation in the obliquity of the ecliptic is stated, and his numbers adopted for that and other elements, as also his solar and lunar tables. The European astronomers were received even more favorably on the establishment of the present dynasty than they had been during the Ming, and their influence is apparent in the great thesaurus entitled *Leüh leih yuen yuen*, compiled under the direct superintendence of the emperor in the first half of the 18th century. This is composed of three parts; the first, entitled *Leüh seang k'au ching*, on astronomy, has several points of divarication from the great work of the Ming. The obliquity of the ecliptic is given from native observation as $23^{\circ} 29' 30''$, being two minutes less than Tycho Brahe's statement. In the correction for the sun's velocity, the new work takes account of the minute motion of the perihelion, and the epoch is changed from 1628 to 1683, but the Ptolemaic theory is still retained. In a supplementary portion, however, the elliptic orbits of the planets are suggested, and Kepler's law of equal areas in equal times is stated. The sun's parallax is given as 10 seconds, instead of 3 minutes, the old number. The circulation of Mercury, Venus, and Mars about the sun is also named, but the whole are still made to revolve about the earth as a centre. The second part of the great work, entitled *Soo le tsing yun*, is on pure mathematics, treating of the theory and use of numbers, geometry, and mensuration, with a description of the European system of algebra, and tables of the numbers of trigonometry and logarithms. The third part, entitled *Leüh leu ching e*, is on music, including a description of the European system, by Thomas Pereyra. The *Ts'ih yuen hae king* is a work on trigonometry by Le Yay, finished in 1248. This is remarkable as being the earliest book containing the *T'een yuen*, a native system of algebra, about which a great deal has been written during the present dynasty.—Although nearly all the dynastic histories have a portion specially allotted to divination, there are few separate works on the subject extant earlier than the Tang dynasty. From that time on there has been no lack of a constant supply, every age having added to the accumulating mass. Under this head are included works on astrology, geomancy, divining by the tortoise, by straws, by diagrams, and in a variety of other ways. The *Hèè ke*

peèn fang shoo is the authorized guide to astrology, published under imperial patronage in 1741. The astrological portion of the almanac is composed according to the principles laid down in this treatise.—Cyclopædias as a class embrace a variety of bulky works, combining to some extent the characteristics of our cyclopædia and concordance. So early as the 2d or 3d century we find it was the custom to make digests of the national literature for the emperor's inspection, and thus originated the class under consideration. Methodically arranged according to subjects, under each heading extracts from former works on the topic are given. Some of the more important of these thesauri were compiled by imperial commission during the Sung dynasty, as the *Sze luy foo*, in 30 books, composed in anomalous verse with a running commentary by the author, Woo Shüh; the *T'ae ping yu lan*, in 1,000 books; and the *Ts'ih foo yuen kwei*, also in 1,000 books. The *Yüh hae*, in 200 books, was also published under imperial patronage in the 12th century. Even these voluminous collections, however, are but pigmies compared with the work that was carried through by the second emperor of the Ming dynasty. With a printed library of 300,000 books, and more than double that number in manuscript, he conceived the idea of resolving the whole into a monster cyclopædia. A commission was appointed to dissect the whole of the existing volumes, classical, historical, philosophical, and literary, embracing astronomy, geography, the occult sciences, medicine, Buddhism, Taoism, and the arts. Three presidents of commission were appointed, under whom were 5 chief directors and 20 sub-directors, besides 2,169 subordinates. The work was completed about the end of 1407, numbering in all 22,877 books, besides 60 books of contents, and was entitled *Yung lö ta t'ien*. A copy was made from the original draught, but the government was deterred from printing by the great outlay that would be necessary. Two other copies were made in the 16th century, but during the troubles that ensued at the close of the Ming, or previously, the original draught and two of the copies were consumed by fire. On the restoration of peace only one of the copies was to be found, and that was deficient 2,422 books. By this manuscript collection 385 ancient and rare works have been preserved, which otherwise would have been irrecoverably lost. Many of these have been since reprinted.—Under the term "Minor Authors" are included a host of works, chiefly miscellaneous narrations, records of marvels, traditions, and anecdotes. A good specimen of the class is the *Yew-yang tsä tsoo*, in 20 books, written in the 8th century. It treats largely of the strange and the supernatural, but it is useful in the investigation of many archæological questions. The *Chuë kang lüh*, in 30 books, was written at the close of the Yuen dynasty, and contains a number of notices regarding the downfall

of the Mongol empire. There is a good deal of miscellaneous information about the affairs of that dynasty, and some few notices relating to countries in the west. The books of the Buddhists alone would form a tolerably extensive library. The translation of Sanskrit works into Chinese was commenced in the 1st century, and continued almost without interruption till the 9th, during which period they added from 2,000 to 3,000 works to the literature of China; and some of these translations are now the only examples of the works to be found in any language, the originals being lost. By far the greater portion of these belong to the three classes *King*, "Classic," *Leih*, "Discipline," and *Lun*, "Metaphysics;" corresponding to the Sanskrit *Sutra*, *Vinaya*, and *Shastra*, including the *Dhārani*, or "Charms." The remaining are chiefly biographical and descriptive, including the *Avadanas* and *Agamas*. The *Lalita vistara*, a life of Buddha, has been four times translated into Chinese, with as many different titles, about the years A. D. 70, 308, 652, and one subsequent. An abstract has also been published under the title *Ching taou ke*. Besides the translations, there is a considerable body of native Buddhist literature, among which may be mentioned the *Fö yuen choo lin*, in 120 books, completed in 668, a comprehensive cyclopædia of the Buddhist religion, detailed in 100 sections.—Among the writings of the Taoists, the *Taou tih king* of Laou Keun, the reputed founder of the sect, will ever stand preëminent. Written in classic diction, and embodying as it does some profound speculations, it has attained an exceptional reputation, and even the fastidious literati think it no shame to study the treatise of the old philosopher. (French by Julien, Paris, 1842; English by Chalmers, London, 1868; German by Plänckner and by Strauss, both Leipsic, 1870.) *Leih tsze* and *Chwang tsze* are two works of the same school, named after their respective authors, who wrote several centuries before the Christian era; and the very age of their productions has insured them a certain degree of deference as ancient writers. Later down in the stream of time we find a great deterioration in Taoism. Gradually its professors gave themselves up to the study of alchemy, the search after the philosopher's stone, the use of charms and amulets; rituals were introduced and images set up in the temples. Thus we have the *Ts'an t'ung k'e*, a treatise on alchemy written in the 2d century; and the well known work of Kō Hung in the 4th century, under the title *Paou p'ö tsze*, is a treatise chiefly on the immortals, alchemy, charms, exorcism, &c., with a section on government and politics. Leu Tung-pin, who flourished during the Tang dynasty, one of the reputed eight immortals, is also a name recognized in the world of letters. His original compositions are published under the title *Leu chin jin wän tseih*, literary and poetical, color-

ed by Taoist views. The *T'ae shang kan ying pien*, or "Book of Rewards and Penalties," professing to be the work of the founder, appears really to be a production of the Sung, but the author is not known. The object of the book is to elucidate the doctrine of future retribution, and it has attained a greater popularity than any other Taoist production. (French by Rémusat, Klaproth, and Julien, 1816, 1828, and 1830; English in the "Canton Register," 1830.)—In poetry and polite literature, the writings of the Chinese are very voluminous. Their poems are most frequently descriptive of nature and natural scenery, domestic life, or the cares of the world. Martial odes are not infrequent. Epic poetry is almost unknown in China; but we find occasional details of historical events. Somewhat singularly, the *Tsoo sze*, or "Elegies of Tsoo," form a class by themselves. These are a series of plaintive poems mainly written by K'ëth Yuen, a minister of the kingdom of Tsoo and relative of the prince. Distinguished by probability of character, he was the victim of slander by his envious colleagues, and ended his existence by throwing himself into a river. His fate is still commemorated in the dragon boat festival. His principal piece, *Le saou*, is a justification of his public character. (German by Pfizmaier, Vienna, 1852; French by Saint-Denys, Paris, 1870.) A good many commentaries have been written on the collection. One of the best editions of the leading piece is the *Le saou keae*, published in 1741, by Koo Ching-t'ëen, with an original exposition.—Another class is termed "Individual Collections," containing the original productions of single authors. Writings of the kind made their appearance at an early period in the Christian era, consisting generally of post-mortem compilations. In the 6th century these began to be divided into several sections according to time or subject. This has been a most prolific class, but one in which comparatively few authors find a place in the ranks of fame. In the bibliographical catalogues of the Sung dynasty there are not found a tenth part of the names of authors in this class contained in those of the Suy and Tang dynasties; and the catalogues of the present day scarcely contain a tenth part of the titles of those recorded as extant during the Sung. Among the most famous is found *Le t'ae p'ih tseih*, the productions of Le Tae-pih, the renowned poet of the Tang dynasty; also *Tung p'o tseuen tseih*, in 115 books, from the pen of the scarcely less celebrated Soo Tung-po, the Sung poet. Both these have been frequently republished with commentaries. The writings of Lüh Kew-yuen, a contemporary and friend of the renowned Choo He, were arranged by his son, and edited by his pupil Yuen Sëe in the 13th century, with the title *Seang shan tseih*, in 28 books. This holds a prominent place among the elegant writers of the Sung dynasty, and consists of letters, memorials to

the throne, records, prefaces and dedications, miscellaneous pieces, poems, sacrificial documents, epitaphs, and sepulchral inscriptions. The emperors of the present dynasty have distinguished themselves in this class more than in any other; and we have a bulky series from the different monarchs. Thus there is a literary collection of 176 books, besides another of poems in 28 books, by the second emperor of the line. His successor has left a collection in 30 books, and the fourth monarch has left collections to the amount of 166 books. Single poems should also come within this category, such as the *Hwa tseer ke*, a love tale written in metrical stanzas. (English by Thoms, "Chinese Courtship," London, 1824.)—In the 6th century a new class of works appeared, which may be termed anthologies. The first of these was compiled about 530, by the son of the founder of the Leang dynasty. It is named *Wän seuen*, and is still one of the best known, the contents being selections from all preceding writers of fame. The subjects into which it is divided are anomalous verse, poems, elegies, sevens verse, decrees, appointments, orders, instructions, essays, manifestations, statements, declarations, accusations, documents, memorials, epistles, notifications, replies, rejoinders, farewells, prefaces, eulogiums, commendations, contracts, historical relations, commendatory historical narrations, discourses, literary gems, admonitions, monumental legends, obituaries, laments, inscriptions, epitaphs, memoirs, dirges, and sacrificial orations. A notable work of this kind, with the title *Koo wän yuen keen*, in 64 books, was published by imperial commission in 1685. It gives an uninterrupted succession of choice literary selections, from the time of the *Tso chuen* down to the end of the Sung dynasty. The annotations of five eminent scholars are appended. A huge compilation of the poetry of the Tang dynasty, under the title *Tseuen tang she*, in 900 books, was issued in 1703, by imperial commission. Upward of 2,200 people were employed in making the collection, which they gathered from private histories, miscellaneous works, monumental records, and every available source, making altogether 48,900 pieces. The writings of Le T'ae-pih and T'oo Foo hold a prominent place in the collection. In the 4th or 5th century, when poetry and composition began to be more under the restraints of fixed and conventional laws, critiques on poetry and literature first made an appearance; and to this class we are indebted for a fund of information on the history, changes, internal mechanism, and chief aim of this much cultivated branch of art. As an example of these works may be noticed the *She hōo yuen ke huō fä ta ching*, in 18 books, by Yu Seang, issued in 1697. The various objects of the themes of poetry are detailed in the order of a cyclopædia. The theme is first explained, then its various applications, followed by quotations from the poets, the ideas embodied, and the application in the successive

parts of a poem. This is followed by a kind of rhyming dictionary, in which a number of quotations are given under each rhyme, and notes for the artistic management of the same.—In the last class are placed the "Rhymes and Songs." The *tsze*, or rhyme, is a composition between prose and poetry, in which the rhyme is repeated at the end of lines of indeterminate length, unfettered by the laws of versification. It first began to be used in the Tang dynasty, but is much more common in recent times, being generally applied to light and trivial subjects. A large work of this class is the *Yu ting leih tae she yu*, in 100 books, published by imperial commission in 1707. This is a comprehensive collection of the choicest rhymes, from the commencement of the art in the Tang dynasty down to the end of the Ming, comprising 1,540 articles, making upward of 9,000 verses. A list of rhymers is included. The *k'eüh*, or songs, embrace dramatic compositions, these being in great part choral effusions. These are barely acknowledged by literary men as forming a part of the literature of the nation, although they are to be found in every book store. A much valued work of the kind is the *Yuen jin pih chung k'eüh*, or "Hundred Plays of the Yuen Dynasty," being a selection from the productions of more than 200 dramatists who wrote about that period. As a dramatic composition the *Se seang ke*, or "Record of the Western Pavilion," holds the highest place in native estimation; and next to it ranks the *Pe-pa-ke*, or "Tale of a Guitar." A well known collection of recent date is entitled the *Chuy pih k'ew*, numbering several tens of dramatic pieces.—It has long been the custom in China to publish large collections of separate works, under the name of *Ts'ung shoo*, sometimes confined to specialties, but very often ranging over the whole field of literature, and containing some choice or rare treatises in each department, according to the compiler's taste or fancy. These may consist of few or many volumes, some collections extending to hundreds. By this means many works are preserved, which would otherwise probably be lost sight of altogether. As an example of these, the *Han wei ts'ung shoo* is a collection of 96 works written during the Han and Wei dynasties, and republished in the Ming dynasty by Ch'ing Yung in the above form. IV. PRINTING. There is reason to believe that printing by wooden blocks was known to the Chinese in the 6th century, though we scarcely hear anything of its application for four centuries later, till the advantages of the art became so manifest that we are told that in 932 Fung Taou and Le Yu, two ministers of the Later Han, memorialized the throne to have the "Nine Classics" revised and printed. The monarch complied, and in about 20 years the copies were in circulation. From that time, so rapidly did this stereotypography advance, that by the end of the 13th century the greater part of the manuscript literature of former ages

was already in print. Some few specimens of the Sung dynasty typography are still to be found in libraries, but they are very rare. The mounted manuscript rolls seem to have been immediately succeeded by long strips, printed on one side, and doubled up in a succession of folds to a book size. This practice is still continued for the sacred books of the Buddhists. The next step in advance was the folded sheets stitched together in volumes, as is the practice at the present day. In the 11th century a scheme for printing by movable clay type was invented by a mechanic named Peñh Shing; we have a minute detail of the process, but there is no account of its having been brought into use; and it is not till the 17th century that we hear of movable type being actually employed in printing. A font of copper types was then made in the imperial printing office, and the *Koo kin t'oo shoo tseih ching*, a gigantic collection of books in 6,000 volumes, was printed with them. The types, however, having fallen out of use, a large proportion of them were purloined by untrustworthy officials, and the remainder melted up to conceal the fraud. In the following century a set of wooden types was made in the same establishment, for the purpose of printing another collection, the *Sze koo tseuen shoo*, noticed above, the printed catalogue of which contains about 3,440 separate works, comprising upward of 78,000 books or sections. The use of these types, however, has been very limited. At present the "Peking Gazette," the daily official organ of the government, is printed with movable wooden type; but both the type and the manipulation are of the clumsiest order, and the impression is one of the rudest specimens of typography that can be found. The printing press has not yet been introduced there. Some private firms have used movable copper types for printing for nearly a century past, and in 1850 we are told of a bookseller in Canton who had cast 150,000 tin types from clay matrices. The specimen of them given in the "Chinese Repository" is very creditable to the artist. About 40 years ago the Rev. Samuel Dyer, of the London missionary society, initiated the use of movable type for China according to the European method. The same work was carried on to perfection by Mr. Cole, and subsequently by Mr. Gamble of the American Presbyterian mission; and so great has been the success of the latter, that not only are his types used by several European firms, but a considerable number of Chinese have also commenced printing with movable types after the western fashion. Some of the natives have also commenced type founding, and even the making of electrotypes. Books are thus being printed and newspapers put into circulation, and it is difficult to foretell what may be the result of this new impetus. V. SINOLOGY. The study of the Chinese language and literature in Europe is almost entirely a growth of the present century, previous to

which very few besides the Roman Catholic missionaries had any knowledge of the subject. The first grammar we hear of was printed at Canton in 1703, in the Mandarin dialect, with the title *Arte de la lengua mandarina*, by Father Francis Varo. Bayer published his *Museum Sincicum* in 2 vols. at St. Petersburg in 1730. This contains a short Mandarin grammar, and another of the dialect of Chinchow in Fokien; also a Chinese vocabulary. Fourmont in France was engaged on kindred studies, and in 1742 published his *Lingua Sinarum Mandarinica Hieroglyphica Grammatica duplex*, which proves to be a slightly modified translation of Varo's grammar. Five years later he published his dissertation on the written language, *Meditationes Sinicae*, a work full of errors. Little else of a philological character appeared in the last century, and any slight interest that might have been created seemed to be on the decline, when Rémusat was appointed professor of the Chinese language in Paris in 1815. The lectures and writings of this distinguished sinologue began to draw the attention of Europeans to China as a great fact, and to invest the literature of the nation with a new interest. His successor, M. Julien, has fully sustained the reputation of the chair. The following are the principal works of a philological character that have appeared: DICTIONARIES. 1. *In Latin. Dictionnaire françois et latin*, composed by Father Basil de Glemona and edited by De Guignes (Paris, 1813). The first part of a supplement to this, by Klaproth, was issued in 1819, containing scarcely a quarter of the whole, but no more was published. De Guignes's was republished at Hong Kong in 1853, without the French, as *Dictionarium Sincico-Latinum*. Gonçalves, *Vocabularium Latino-Sincicum* (Macao, 1836), *Lexicon Manuale Latino-Sincicum* (1839), and *Lexicon Magnum Latino-Sincicum* (1841). Callery, *Systema Phonetico-scripturae Sinicae* (Macao, 1841), arranged on a peculiar phonetic system of his own device. Perny, *Vocabularium Latino-Sincicum* (China, 1861). 2. *Portuguese. Dicionario Portuguez-China* (Macao, 1831), and *Dicionario China-Portuguez* (1833). 3. *French. Dictionnaire françois-latin-chinois de la langue mandarine parlée* (Paris, 1869), with an appendix as large (1872). 4. *Russian. Grafitcheskaya sistema kitaiskikh ieroglifov* (St. Petersburg, 1867); Esaiya, *Rusko-kitaiski slovar* (Peking, 1867), and *Predovlenie k' rusko-kitaiskomu slovariu* (1870). 5. *English. Morrison, "Dictionary of the Chinese Language"* (6 vols. 4to, Macao, 1815-'23); 2d part, "Alphabetic Chinese and English" (republished at Shanghai, 2 vols. 8vo, 1865); "Vocabulary of the Canton Dialect" (Macao, 1828); Medhurst, "Chinese and English Dictionary" (Batavia, 1842-'3), and "English and Chinese Dictionary" (Shanghai, 1847-'8); Lobscheid, "English and Chinese Dictionary" (4 vols., Hong Kong, 1869), and "A Chinese and English Dictionary"

(1871); Doolittle, "Vocabulary and Handbook of the Chinese Language" (2 vols. 4to, Foochow and Shanghai, 1872-'3); Kwong Tsün-fuh, "English and Chinese Lexicon" (Hong Kong, 1868); Williams, "English and Chinese Vocabulary, in the Court Dialect" (Macao, 1844), and "Tonic Dictionary of the Chinese Language, in the Canton Dialect" (Canton, 1856); Chalmers, "English and Cantonese Pocket Dictionary" (Hong Kong, 1859); Stent, "Chinese and English Vocabulary, in the Pekinese Dialect" (Shanghai, 1871); Medhurst, "Dictionary of the Hokkëen Dialect" (Macao, 1832); Maclay and Baldwin, "Alphabetic Dictionary of the Chinese Language, in the Foochow Dialect" (Foochow, 1870).—GRAMMARS. 1. *Latin*. Premare, *Notitia Linguae Sinicae* (Malacca, 1831). 2. *Portuguese*. Gonçalves, *Arte China* (Macao, 1829). 3. *French*. Rémusat, *Éléments de la grammaire chinoise* (Paris, 1822); this has been republished, edited by De Rosny; Bazin, *Mémoire sur les principes généraux du chinois vulgaire* (Paris, 1845), and *Grammaire mandarine* (1856); Rochet, *Manuel pratique de la langue chinoise vulgaire* (Paris, 1846); Julien, *Syntaxe nouvelle de la langue chinoise* (Paris, 1869-'70). 4. *German*. Endlicher, *Anfangsgründe der chinesischen Grammatik* (Vienna, 1845); Schott, *Chinesische Sprachlehre* (Berlin, 1857). 5. *Russian*. Hyakinth, *Kitaiskaya grammatika* (St. Petersburg, 1838). 6. *English*. Marshman, *Clavis Sinica* (Serampore, 1814); Morrison, "A Grammar of the Chinese Language" (Serampore, 1816); Gützlaff, "Notices on Chinese Grammar" (Batavia, 1842); J. G. Bridgman, "The *Notitia Linguae Sinicae* of Premare, translated into English" (Canton, 1847); Summers, "Handbook of the Chinese Language" (Oxford, 1863), and "The Rudiments of the Chinese Language" (London, 1864); Lobscheid, "Grammar of the Chinese Language" (Hong Kong, 1864); Edkins, "A Grammar of Colloquial Chinese, as exhibited in the Shanghai Dialect" (Shanghai, 1853; 2d ed., 1868), and "A Grammar of the Chinese Colloquial Language, commonly called the Mandarin Dialect" (1857; 2d ed., 1864); Baldwin, "Manual of the Foochow Dialect" (Foochow, 1871).—Among the phrase books and manuals we may notice Morrison's "Dialogues and Detached Sentences in the Chinese Language" (Macao, 1816); Shaou-tih's "English and Chinese Student's Assistant" (Malacca, 1826); Legge's "Lexilogus of the English, Malay, and Chinese Languages" (Malacca, 1841); Bridgman's "Chinese Chrestomathy in the Canton Dialect" (Macao, 1841); Williams's "Easy Lessons in Chinese" (Macao, 1842); Medhurst's "Chinese Dialogues" (Shanghai, 1844; revised ed. by his son, 1863); Edkins's "Chinese Conversations" (Shanghai, 1852); "Doty's Anglo-Chinese Manual, with Romanized Colloquial in the Amoy Dialect" (Canton, 1853); Hernisz's "Guide to Conversation in English and Chinese" (Boston, 1854); Lob-

scheid's "Beginner's First Book, or Vocabulary of the Canton Dialect" (Hong Kong, 1858); Wade's "*Hsin-ching-lu*, or Book of Experiments" (Hong Kong, 1859); Macgowan's "Collection of Phrases in the Shanghai Dialect" (Shanghai, 1862); Thoms's "The Chinese Speaker" (Ningpo, 1846); Edkins's "Progressive Lessons in the Chinese Spoken Language" (Shanghai, 1862); Martin's "The Analytical Reader" (Shanghai, 1863); Lobscheid's "Select Phrases and Reading Lessons in the Canton Dialect," and "Tourist's Guide and Merchant's Manual" (Hong Kong, 1864); Rubery's "Easy Phrases in the Canton Dialect" (Canton, 1866); Lobscheid's "Household Companion and Student's First Assistant" (Hong Kong, 1867); Wade's "*Yü-yen Teü-erh Chi*, a Progressive Course designed to assist the Student of Colloquial Chinese," and "*Wên-chien Tzü-erh Chi*, a Series of Papers selected as Specimens of Documentary Chinese" (London, 1867); Macgowan's "A Manual of the Amoy Colloquial" (Hong Kong, 1869); and Wylie's "Notes on Chinese Literature" (Shanghai, 1867).

CHINANDEGA, a town in the Occidental department of Nicaragua, situated on the plain of Leon, about 6 m. from Realejo on the Pacific, which is its seaport; pop. about 15,000. It lies in the midst of a district of extraordinary fertility and agricultural resources, which, however, are but poorly developed. It consists of two contiguous towns, Old and New Chinandega, and is almost the only place in Nicaragua that has grown since the separation from Spain; a considerable part of the inhabitants of Leon, tired of the turmoils and dangers of the political capital, having sought here comparative quiet and security. Many of the houses, which are straggling and devoid of architectural taste, are surrounded by gardens and plantations. During the existence of the first Central American confederacy, the congress met at Chinandega.

CHINA SEA (Chinese, *Nan-hai*, Southern sea), that portion of the Pacific cut off from the main ocean by a chain of islands, of which Borneo, the Philippines, and Formosa are the principal. It is bounded E. by this chain of islands, and W. by China, Anam, and the Malay peninsula. On the N. it opens into the Tang-hai, or Eastern sea, through the Formosa channel; on the E. into the Pacific through the Balintang channel, between the islands of Formosa and Luzon; on the S. into the Indian ocean through the sea and strait of Sunda; on the S. W. into the sea of Bengal through the strait of Malacca. Its extreme length, S. W. to N. E., from the extremity of the Malay peninsula to Formosa, is about 2,000 m.; average breadth, W. to E., from the continent of Asia to the chain of islands, about 750 m. It has two deep indentations: the gulf of Tonquin, between China and Anam; and the gulf of Siam, between Siam and the Malay peninsula. The islands are few, Hainan being the only one of considerable size.

The Canton, Mekong, and Menan are the principal rivers which fall into it. Canton, Manila, and Singapore are the most important ports on its coasts.

CHINA WARE. See PORCELAIN.

CHINCHA ISLANDS, a group of three small islets off the coast of Peru, celebrated for their

deposits of guano, from which the Peruvian government derives a revenue larger than from all other sources combined. They lie about 12 m. from the port of Pisco, in the department of Lima, in lat. $13^{\circ} 44' S.$, lon. $76^{\circ} 13' W.$ They are of granitic formation, the rock being of a bright red color, composed of red

Chincha Islands.

feldspar, white quartz, and a little mica, and are evidently the result of volcanic upheavals. The shores are bold and precipitous, rising usually 25 or 30 ft. above the sea, but in some places much higher, and increasing in height toward the centre. The cliffs are perforated with caves and arches, the homes of multitudes of penguins and other aquatic fowl; and the guano is honeycombed with the nests of small birds, which frequent the islands in immense flocks. The surface, which is destitute of vege-

northern island, and chief of the group, is about four fifths of a mile in length and one third in breadth. It has been estimated to contain 17,000,000 tons of guano, and the others about 25,000,000; but these figures are probably exaggerated. About one half of the deposit of this island has already been excavated. (See GUANO.)

CHINCHAYCOCHA, a lake of Peru, in the department of Junin, about 10 m. S. S. E. of Pasco. Its N. W. extremity is in lat. $10^{\circ} 42' S.$, lon. $75^{\circ} 40' W.$ It is 13,000 ft. above the sea, and is 35 m. in length and 7 in width. With the exception of Lakes Titicaca and Maracaibo, it is the largest sheet of fresh water in South America. The principal branch of the Mantaro or Jauja, one of the largest tributaries of the Ucayali, issues from it. As it loses by this and other outlets more water than it receives from streams flowing into it, it is undoubtedly fed by subterraneous springs. Its banks are marshy and are frequented by many water fowl. Its S. W. extremity is crossed by a marshy piece of ground, called the Calzada, which forms a means of communication between the two shores.

CHINCH BUG, a small hemipterous insect (*Rhyparochromus devastator*, Say), which occasionally commits great depredations in wheat and corn fields, especially in the southern and western states. It is about $\frac{3}{8}$ of an inch long, with

Guano Workings in the North Island.

tation, is covered with guano more than 100 ft. in depth. The excavating and shipping of this deposit employs 200 or 300 laborers, mostly convicts and Chinese coolies, who have formed a temporary settlement on the principal island. They live in huts of bulrush matting, stretched on bamboo supports, which furnish a sufficient shelter in this dry climate. All means of subsistence, even drinking water, have to be brought from the mainland. More than 100 vessels are usually lying here, loading or waiting for cargoes. Chincha, the

Chinch Bug (*Rhyparochromus devastator*).

white wing covers, upon each of which is a short central line and a large marginal oval spot of black; the rest of the body is black and downy; the beak, legs, base of antennæ, and

hinder edge of thorax, reddish yellow; and fore part of the thorax grayish. The young are wingless, at first bright red, changing gradually to the colors of the adult. The eggs are laid in the ground, and the young appear on the wheat about the middle of June, and may be seen on grains and grasses all summer.

CHINCHILLA, a little animal of the family *chinchillidæ* and order *rodentia*. The family is defined by Mr. Bennett, to whom the world owes most of what is known concerning this species, as follows: The incisors are $\frac{2}{2}$, simple; molars $\frac{4-4}{4}$, consisting of 2 or 3 tænia or ribbon-like lamellæ or plates, parallel with each other, entirely surrounded by a vitreous substance; the crowns exactly opposite to each other, and flattened by attrition. The posterior limbs are nearly twice as long as the anterior. The tail, produced, has long and bristly hairs about the tip and on the upper side. Anterior feet five-toed; posterior feet four-toed, the nails small and subfalcar; the tail rather long. This is the well known fur-bearing chinchilla, the skins of which are so much used

Chinchilla lanigera.

in the winter dress of ladies. The *chinchillidæ* are gregarious and subterranean in their habits, and mild in their disposition. Mr. Waterhouse, in his "Natural History of Mammalia," makes the *chinchillidæ* a sub-family of the family *hystrioidæ*. There are two species of this genus, *C. lanigera* and *C. brevicaudata* (Waterhouse); the former, to which the following remarks particularly apply, peculiar to Chili; the latter, somewhat larger, coarser, and less known, to Peru. The length of the body of this beautiful little creature is 9 inches, and that of the tail nearly 5. Its proportions are close set, and its limbs rather short, the posterior being considerably longer than the anterior. The fur is long, thick, close, woolly, somewhat crisped and entangled together, grayish or ash-colored above and paler beneath. The form of the head resembles that of the rabbit; the eyes are full, large, and black, and the ears broad, naked, rounded at the tips, and nearly as long as the head. The mustaches are plentiful and very long, the longest being twice the length of the head, some of them black, others white. The tail is about half the length of the body, of equal thickness throughout, and

covered with long bushy hairs; it is usually kept turned upward toward the back, but not reverted as in the squirrels. Mr. Yarrell, who dissected one that died in the menagerie of the zoölogical society in London, has given the best account of it in the "Proceedings" of the society; and while he points out that in the possession of an extra toe on each of the feet it requires the generic distinction claimed for it by Mr. Bennett and Dr. Gray, he adds that the resemblance of the skeleton to that of the jerboa is also remarkable, particularly in the form of the head, the excessive development of the auditory cavities, and the small size of the anterior extremities compared with the hind legs. Although an extensive trade has been carried on in the skins of this interesting little animal, it is only within a few years that it has been seen alive in this country. Molina says: "It lives in burrows underground, in the open country of the northern part of Chili, and is very fond of being in company with others of its species. It feeds upon the roots of various bulbous plants which grow abundantly in those parts, and produces twice a year five or six young ones. It is so docile and mild in temper that, if taken into the hands, it neither bites nor tries to escape, but seems to take pleasure in being caressed." Mr. Bennett says: "To the account of its habits given by Molina, we can only add that it usually sits on its haunches, and is even able to raise itself up and stand upon its hinder feet. It feeds in a sitting posture, grasping its food and conveying it to its mouth by means of its fore paws." It breeds freely in confinement.

CHINCHILLA, a city of Spain, in the province and 10 m. S. E. of the city of Albacete; pop. about 12,500. It stands on an abrupt hill, and is surrounded by a wall built in 1837 out of remains of older ones. It contains a handsome parish church, several chapels and convents, a prison, hospital, theatre, cemetery, poorhouse, barracks, and Latin and primary schools. There are various manufactures, and trade in cotton, wool, grain, and fruits. Quarries of granite, alabaster, gypsum, and limestone are wrought in the vicinity. The railroad from Madrid to Valencia passes about 3 m. from the city.

CHINGLEPUT, an inland town of British India, in the Carnatic, presidency of Madras, capital of an extensive district, 35 m. S. S. W. of Madras; pop. about 7,500. It consists of one long street, and adjoins another town or collection of dwellings called Nullam. An artificial lake or tank and a feeder of the Palar river supply the place with water, and the climate is salubrious excepting during the dry season, when the decayed matter in the tank produces malaria. Rice is the principal article of trade, and pottery is manufactured. The fort, once of considerable strength, is divided into two parts by a rampart and a ditch, the E. part being elevated and constituting an inner fort, with the government buildings of the district.

The fort was taken by the French in 1751, and retaken by the English under Clive in 1752.

CHIN-INDIA, sometimes called India beyond the Ganges, and also Indo-China, the peninsula lying between the China sea and the sea of Bengal, comprising Burmah, Siam, Anam, and the Malay peninsula.

CHING-KING, a Chinese province. See SHING-KING.

CHINON, a town of France, in the department of Indre-et-Loire, 25 m. S. W. of Tours; pop. in 1866, 6,895. It is pleasantly situated on the right bank of the Vienne. The principal public buildings are the town hall and the communal college. Henry II. of England died there, and near it Rabelais was born. It was the favorite residence of the French monarchs from Philip Augustus to Henry IV. The ruins of the castle where Charles VII. resided when Paris was occupied by the English, and where Joan of Arc presented herself to that monarch, are still seen. The principal articles of trade are grain, wine, prunes (called prunes of Tours), and other dried and fresh fruits.

CHINOOKS, a family of Indian tribes on the N. W. coast of North America, who formerly inhabited both banks of the Columbia river from its mouth to the Grand Dalles, broken up into numerous bands. The Chinooks proper were on the north side, and the Clatsops on the south and along the coast. The language varied as the tribes extended into the interior. In all its dialects it is very complicated and difficult to pronounce. This led to the composition of the Chinook jargon, a sort of *lingua franca* used by the traders, containing some Chinook words with terms from the French, English, and many Indian languages, all corrupted into a new form. The Chinook Indians are now nearly extinct, a small band on the Chehalis reservation in Washington territory representing them in 1873. A vocabulary of their language, by George Gibbs, was published at New York in 1863; and a "Dictionary of the Chinook Jargon," thoroughly analyzed by the same scholar, in the same year.

CHINSOORA, or **Chinsura**, a town of Bengal, British India, on the right bank of the Hoogly, 20 m. above Calcutta; lat. 22° 53' N., lon. 88° 23' E.; pop. about 14,000. It extends about half a mile along the river, is neatly and solidly built, and is an important station for European troops. The barracks, hospital, and other buildings connected with the military establishment are on a magnificent scale, and since 1858 have been greatly enlarged. The barracks are intended to accommodate 5,000 men. Besides the Hoogly college, a government institution, the town has several schools and a chapel. It is famous for the manufacture of cheroots. It was settled by the Dutch in 1657, and in its small, quaint-looking dwellings bears many traces of its founders. In 1759 the British under Col. Forde defeated near here a Dutch force which had attempted to check their march on Chandernagore. When Hol-

land was occupied by the French in 1795, the British offered to retain Chinsora for the stadtholder; but their proposition being rejected, they took it by force, and retained possession till the peace of 1814. It formed part of the territory ceded to the British by the king of the Netherlands in 1824, in exchange for possessions in Sumatra.

CHIOGGIA, or **Chiozza** (anc. *Fossa Clodia*, and *Clugia*), a seaport of Italy, in the province of Udine, on the Adriatic, 15 m. S. of Venice; pop. in 1872, 26,336. It is situated on a small island at the S. end of the lagoon of Venice, a little N. of the embouchure of the Brenta, is built partly on piles, and communicates with the mainland by a low stone bridge of 43 arches. The harbor, which has 17 feet of water, is considered one of the best fortified in the vicinity of Venice, being defended by a number of batteries and the forts of Caraman and San Felice. It is usually crowded with fishing and coasting vessels, in which a large part of the population find employment. It is a bishop's see, and contains several churches, a gymnasium, a high seminary, orphan asylum, hospital, workhouse, theatre, custom house, ship yards, salt works, and manufactories of lace, cordage, and other articles. It is the centre of an active trade in Italian and German products, which is facilitated by canals communicating with the Brenta, Adige, and Po. Titian is said to have found models for some of his finest works in the women of Chioggia, who have long been noted for beauty; and Léopold Robert and other modern painters have often resorted for inspiration to the same source. In 1379 the Genoese took possession of the island, but after a struggle of two years, to which the name of the war of Chioggia has been given, were forced to yield it to Venice.

CHIOS. See SCIO.

CHIPMAN. **I. Nathaniel**, LL. D., an American jurist, born at Salisbury, Conn., Nov. 15, 1752, died at Middlebury, Vt., Feb. 15, 1843. He was educated at Yale college, during his senior year obtained a lieutenant's commission in the American army, was on duty at Valley Forge in the winter of 1777-'8, and was present at the battle of Monmouth. Resigning his commission, Oct. 10, 1778, he repaired to Litchfield, Conn., and was admitted to the bar in 1779. He then removed to Tinmouth, Vt., where he commenced practice, and served as state's attorney for four years. In 1786 he was elected assistant judge of the supreme court, being the first lawyer who had been placed upon the bench in Vermont. In 1789 he was elected chief justice, and was appointed one of the commissioners to adjust the differences between Vermont and New York. In 1791 he was a member of the convention called to decide whether Vermont should join the Union, and he was appointed a joint commissioner with Lewis R. Morris to attend congress and negotiate for the admission of the state. In the same year he was appointed by Wash-

ington judge of the United States court for the district of Vermont. In 1793 he published a small work entitled "Sketches of the Principles of Government," and a volume of "Reports and Dissertations," containing reports of cases decided while he was chief justice, with dissertations on the statute adopting the common law of England, the statute of offsets on negotiable notes, and the statute of conveyances. He resigned his office in 1793, and resumed practice till October, 1796, when he was again elected chief justice of the state supreme court. In 1796 he was appointed one of a committee to revise a code of statute laws for Vermont. The revised laws of 1797 were written by him. In 1797 he was elected a senator in congress. In 1813 he was chosen one of the council of censors to examine the state constitution and to propose amendments. In the same year he was again elected chief justice of the supreme court, and continued in office two years. From 1816 to 1843 he was professor of law in Middlebury college. In 1833 he published "Principles of Government; a Treatise on Free Institutions, including the Constitution of the United States," containing portions of his former treatise. **II. Daniel, LL. D.**, an American jurist, brother of the preceding, born at Salisbury, Conn., in 1762, died at Rip-ton, Vt., April 23, 1850. He was educated at Dartmouth college, was admitted to the bar at Middlebury, Vt., in 1790, and there practised law for many years. He was state's attorney for Addison county for eight years subsequent to 1797, for a long period represented Middlebury in the legislature, and was a member of congress in 1815-'17. He was professor of law and jurisprudence in Middlebury college from 1806 to 1816, when he was succeeded by his brother Nathaniel. He was the first official reporter of the decisions of the supreme court of Vermont, and in 1824-'5 published two volumes of reports. In 1822 he published "An Essay on the Law of Contracts for the Payment of Specific Articles;" in 1849, memoirs of Col. Seth Warner and Gov. Thomas Chittenden; and in 1846, a biography of Nathaniel Chipman.

CHIPMUNK, the name usually given to the ground squirrel (*tamias*, Illig). The ground squirrels have cheek pouches extending to the hind head and opening internally; the tail is shorter than the body, the feet large, with well developed claws for digging, and the anterior basal plate of the zygoma perforated by a nearly circular foramen; the permanent upper molars are four; the tail is not bushy, and there are three to five longitudinal stripes on the back. They burrow in the ground near the roots of trees, and their nest is well supplied with winter food. They form a connecting link between the squirrels proper and the spermophiles or prairie squirrels. The common American ground, striped, or cheeping squirrel, chipmunk, or hackee (*T. striatus*), has the body 5 to 6 in. long, and the tail about 4½;

on the back and sides are five longitudinal black stripes, not extending over the rump, the outer two on each side separated only by a white line; rump pale chestnut, and the upper parts generally finely grizzled yellowish gray and brown; lids and under parts white, and a downy white spot behind the ears. It varies but little, and is found from Canada and Lake Superior to Virginia and Missouri. It is lively, playful, and busy, and may be said to occupy among mammals the place of the wren among birds; it is very commonly seen running along the fences and walls in New England, cheeping like a young chicken, the cheek pouches distended with nuts or seeds, occasionally stopping and standing upright, watching against enemies, and disappearing in some hole at the least alarm. The young are born in May, four or five at a birth. They are scarcely injurious to the farmer, not disturbing the grain before it is ripe, and only gleaning after the harvest; they feed chiefly on nuts, wheat, buckwheat, Indian corn, cherry stones, and grass seeds, with which their winter burrows are plenti-

Chipmunk.

fully supplied. They are easily captured in traps, but are not readily tamed, and are rarely seen in cages. Their worst enemy is the weasel, which pursues them into their burrows. The Missouri chipmunk (*T. quadrivittatus*) is smaller, with the intervals between the stripes all grayish white; beneath it is dirty grayish white, and the general color is more ferruginous; it most resembles the *T. Pallasii* of N. Asia and Siberia, and occurs about and west of the Rocky mountains. Other species are found on the Pacific coast.

CHIPPENHAM, a municipal and parliamentary borough of Wiltshire, England, on the left bank of the Avon, crossed here by a bridge of 22 arches, 12 m. N. E. of Bath; pop. in 1871, 8,282. It is a handsome town, with an ancient Gothic parish church. Schools are numerous, and there are several charitable institutions. Tanning and malting are carried on, and there are extensive iron works. Silk and wool are manufactured to some extent, but the latter industry has much declined. Mineral springs are in the vicinity.

CHIPPEWA, a river of Wisconsin, called by the Indians the Ojibway, or Ojibbeway. It

ries in the N. part of the state, flows in a S. W. direction through a country mostly covered with pine forests, and after a course of over 200 m. enters the Mississippi near Lake Pepin, 85 m. below St. Paul, Minnesota. It is about 500 yards wide at its mouth.

CHIPPEWA. I. A N. E. county of Michigan, bordering on Lakes Superior and Huron, and bounded E. by the river St. Mary; area, about 1,500 sq. m.; pop. in 1870, 1,689. It includes several islands. The surface is hilly and partly covered with forests of pine. The chief productions in 1870 were 2,005 bushels of oats, 9,227 of potatoes, and 940 tons of hay. The value of live stock was \$16,278. Capital, Sault Ste. Marie. **II.** A N. W. county of Wisconsin, traversed by the Chippewa river and several affluents; area, about 4,000 sq. m.; pop. in 1870, 8,311. The surface is uneven, and forests of pine and other trees abound. Sandstone is common. The chief productions in 1870 were 131,505 bushels of wheat, 32,751 of Indian corn, 166,944 of oats, 67,890 of potatoes, and 8,255 tons of hay. There were 928 horses, 1,466 milch cows, 2,559 other cattle, and 2,478 swine. There were 3 flour mills, 14 saw mills, and 2 breweries. Capital, Chippewa Falls. **III.** A S. W. county of Minnesota, bounded S. W. by the Minnesota river, and intersected by the Chippewa and Chetomba; area, 2,445 sq. m.; pop. in 1870, 1,467. The St. Paul and Pacific railroad just touches the N. E. corner. The chief productions in 1870 were 9,318 bushels of wheat, 3,550 of Indian corn, 2,465 of oats, 4,993 tons of hay, and 64,830 lbs. of butter. There were 158 horses, 584 milch cows, 1,501 other cattle, and 256 swine. Capital, Chippewa City.

CHIPPEWA, a village and port of entry in the province of Ontario, Canada, in the township of Willoughby, Welland co.; pop. about 1,200. It is situated at the confluence of the Chippewa and Niagara rivers, 2 m. above the falls, and contains an extensive steam engine manufactory, and one of the largest factories of stoves in the province.—A battle was fought here, July 5, 1814, between the Americans under Gen. Brown and the British under Gen. Riall. On the 3d the Americans crossed the Niagara river, surprised Fort Erie, and the next day moved down the river. On the 5th they came upon the enemy, concealed behind a wood. After a series of attacks and counter-attacks, the British were finally repulsed, and retreated across Chippewa creek, burning the bridge behind them. The Americans in this action were actually commanded by Gen. Scott, Gen. Brown not being in the field. The Americans engaged numbered 1,900; their loss was 68 killed and 267 wounded. The British numbered 2,100, and lost 138 killed and 365 wounded.

CHIPPEWAS. See OJIBWAYS.

CHIPPEWYANS. See TINNE.

CHIQUIMULA. I. A department of Guatemala, Central America, lying on the gulf of

Honduras, and N. and W. of the states of Honduras and San Salvador; area, about 4,000 sq. m.; pop. about 75,000. The river Motagua, which nearly bisects it, emptying into the bay of Honduras, is its principal stream. San Tomas de Castillo, at its mouth, has one of the best ports in Central America. In 1844 a Belgian colony was established here, but it failed gradually, and in 1854 Guatemala resumed its authority over the settlement, and it is now nearly deserted. Izabal, the only other port of Guatemala, is also in Chiquimula. It is on the south shore of the gulf of Dulce, and can be reached only by vessels of light draught. **II. Chiquimula de la Sierra**, the capital of the department, about 75 N. E. of the city of Guatemala; pop. about 6,000. It is the centre of an active trade, and maize is raised in considerable quantities in its vicinity. It has a large church and a fountain in the principal square. **III. Isthmus of**, that part of the department of Chiquimula along the Caribbean sea, extending about 70 m. from the mouth of the river Motagua to the N. W. extremity of the bay of Honduras. The distance from the Atlantic to the Pacific at this point is 150 m.

CHIQUITOS, a once powerful Indian tribe of South America, inhabiting the country west of the river Paraguay, in the present province of Chiquitos in Bolivia. They are described by Charlevoix and other early writers as an intelligent and independent race, brave and with warlike instincts, and excelling in many exercises. They occupied the hills and elevated plateaus, lived in families, united agriculture with the chase, and, possessing large resources, were always numerous. They were first visited by Alexis Garcia, a Portuguese, who, having been sent from the coast of Brazil to explore the interior of Paraguay, about 1525, conceived the bold project of reaching Peru across the wilderness of the Gran Chaco. Gathering a force of 2,000 Indians, he went up the Paraguay above the site of Asuncion, and thence passed in a N. W. direction through the S. portion of Chiquitos, fighting his way through the thickly populated country until he reached the Andes, where he was murdered by his Indian allies. In 1537 Juan de Ayolas perished in conducting a similar expedition. Other adventurers failed in bringing to subjection this brave people, and it was not till 1691 that a permanent settlement was made among them. In that year Father Arce, a Jesuit, established the mission of San Xavier, and from that time till their expulsion the Jesuits retained an unbounded influence over the natives. Other missions soon followed. In 1696 San Rafael was built; in 1706, San José and San Juan; in 1707, Concepcion and San Ignacio; and soon afterward Santa Anna and San Miguel. Santiago was founded in 1740, and San Corazon in 1751. Occupying a comparatively isolated position, these missions enjoyed a peaceful and harmonious existence. Under the instruction of the fathers the Indians acquired many industrial arts, cul-

tivated the fields, established manufactories, and carried on a remunerative trade with the neighboring Spanish settlements. D'Orbigny and other writers assert that these towns were in advance of those of the Spaniards, that their manufactures were better, and the produce of their lands superior and more abundant. Their churches and mission buildings rivalled any in the new world, and were remarkable for the costliness of their decorations. Music and singing were taught, and the church choirs were composed of natives, who attained a rare degree of excellence in the art. Thus, in 50 years after the arrival of the fathers, the Chiquitos and the neighboring tribes had become moulded into a civilized race. One of the most wonderful changes effected was in the language. Until the latter part of the 17th century, so slight was the intercourse between the tribes that 13 different languages were spoken, of which the Chiquito was the most general. The Jesuits proceeded to supplant the others, with the object of making the latter the language of all the Indians settled in the missions. Chiquito Indians were sent among the surrounding tribes as instructors, prayers and services were read in that tongue only, and all business transactions were conducted in it. These efforts gradually became successful, and now none but the Chiquito tongue is used by the Indians of the province. At the time of the expulsion of the Jesuits, in 1767, the missions had acquired an extraordinary degree of prosperity; but with the withdrawal of the fostering care which the fathers had always exercised over their converts, and the bad administration of the government, they began to decline. Many of the Indians fled to the forests and relapsed into the rude ways of their fathers; the thriving villages decreased in population, and the splendid buildings and churches of the missions fell into decay. In the beginning of the present century, 34 years after the decree of expulsion, more than two thirds of the original inhabitants had disappeared; and the population is estimated now at only about 25,000.

CHIQUITOS, a province of Bolivia, in the department of Santa Cruz de la Sierra, between lat. 14° and 21° S., and lon. 57° 30' and 62° 30' W., bounded E. by the Paraguay river, N. by marshes and immense forests lying between it and the country of the Moxos, W. by the province of Santa Cruz, and S. by the Gran Chaco; area, 108,000 sq. m.; pop. about 28,000. It forms the middle part of a great plain extending N. and S. at the eastern base of the Andes, from which rises a mountain system, composed of several chains of hills, which divides the waters flowing into the Amazon from those which feed the Plata. The rivers belonging to the former are the San Miguel, Serre, Rio Verde, Baures, and Barbados, tributaries of the Guaporé. On the other side of the mountains, the Tucabaca, San Rafael, Latiriquiqui, and San Tomas all flow into the Paraguay.

The country abounds in marshes and freshwater lakes; but the largest bodies of water are the salinas of San José and Santiago, which yield excellent salt. The climate is warm, but not so hot as its position would indicate, and is generally healthy, intermittent fevers not prevailing to any extent. The soil is rich, yet little cultivated, there being no markets for produce. Cotton, sugar, and tamarinds, however, are exported to some extent.

CHIRIQUI, a province on the isthmus and in the state of Panama, United States of Colombia, bounded N. by the Caribbean sea, S. by the Pacific, E. by the province of Veragua, and W. by Costa Rica; area, 500 sq. m.; pop. about 18,000. It is unsurpassed in diversity of surface, fertility of soil, and luxuriance of vegetation; has an abundance of land fit for pasture or tillage, contains extensive beds of good coal, and has commodious harbors, both on the Caribbean sea and the Pacific. The coast is sickly, but many districts in the interior are healthy. Its resources have been but imperfectly developed. The chief town, David, on the Pacific coast, has a population of about 3,000. The isthmus here is 46 m. wide. Its principal river, the Chiriqui, empties into the lagoon of the same name, formed by the Caribbean sea. The lagoon is a spacious bay, extending about 90 m. along the coast, and from 40 to 50 m. inland. It has three entrances, the largest of which is 2 m. wide, with an average depth of about 100 ft. It is separated from the Caribbean sea by the islands forming the archipelago of Chiriqui, 11 in number, the principal of which is Boca del Toro. There is a mountain called Chiriqui on the borders of Costa Rica, and a desert of the same name, peopled by about 5,000 savages.

CHIROMANCY (Gr. *χείρ*, hand, and *μαντεία*, divination), the pretended art of judging the character and foretelling the fortune of a person from the aspect of his hand. The elements to be observed are the thumb and fingers, nails, joints, lines, and mountains. There are 15 joints, three to each finger, two to the thumb, and one connecting the hand and arm. There are four principal lines. The line of life (*linea vitalis*), which is the most important, curves from the side of the hand between the thumb and forefinger, around the base of the thumb, to the centre of the wrist joint. The line of health (*linea naturalis*, or *cephalica*) has the same origin as the line of life, and extends directly across near the centre of the hand. The line of fortune or happiness (*linea mensalis*) is nearly parallel to the latter, and extends from near the base of the forefinger to near the base of the little finger. The line of the joint (*linea rasceta*) is the fold which marks the passage from the hand to the arm. There is a fifth line (*linea hepatica*), not found in all hands, which extends from the middle of the wrist joint to the base of the little finger. There are seven mountains (*montes*), named after the seven planets of the ancients. The elevation

at the base of the thumb is the mountain of Venus; forefinger, that of Jupiter; middle finger, that of Saturn; third or ring finger, that of the sun; little finger, that of Mercury. The elevation on the lower side of the hand, between the mountain of Mercury (from which it is separated by the line of fortune) and the lower extremity of the line of health, is the mountain of the moon; and the elevation between the mountain of the moon and the line of the joint is the mountain of Mars. Among the laws of chiromancy are the following: The observations must always be upon the person's left hand. If the line or fold of the joint presents four distinct, equal, and straight furrows, the person will speedily attain to wealth and honors; if short perpendicular lines proceed from it toward the arm, he will be exiled; if toward the palm of the hand, he will go upon a long journey. If the line of life is regular and deeply colored, it predicts a long and happy life; if it is tortuous, colorless, feebly marked, and broken, it announces ill health and short life; if it is narrow, but long and well colored, it indicates wisdom and ingenuity; if deep and unequally colored, it denotes malice; if cut near the centre by two slight but well defined transverse lines, it is the sign of approaching death. If the line of health (also called the line of wit) is clear and regular, it indicates excellence of mind and body; if the opposite, it indicates feebleness, timidity, and illness. The line of fortune, according to its various phases of distinctness and directness, indicates happiness or misery, and a pleasant or unpleasant natural temper; if it begins close to the upper side of the hand, it indicates pride; if very red in its upper part, envy; if crossed by one line so as to form the Latin cross, generosity; if by several small lines near the middle, duplicity. The line of the triangle, when present, usually promises great success after great difficulties. The mountain of Venus, when smooth and unfurrowed, indicates a happy temperament; that of Jupiter, a heart inclined to virtue; that of Saturn, simplicity of character and love of labor; that of the sun, vivacity and eloquence; that of Mercury, firmness in men and modesty in women; that of the moon, tranquillity of mind, inclining to melancholy; and that of Mars, courage and heroism. The various lines and shades of color on each of the mountains have special significance. Small lines appearing near the little finger, parallel with the line of fortune, are the *lineæ matrimoniales*, and promise a happy marriage. The milky way (*via lactea*) extends downward on the mountain of the moon from the line of the joint toward the little finger. If this is long apparent, it signifies success in study and the arts, or fortune in a foreign land. Small white spots on the nails announce happiness and the fulfilment of hopes, at a more remote period according as they are near the root of the nail.—Chiromancy was practised throughout pagan antiquity, was regarded by

Aristotle as a certain science, and was in great esteem among the disciples of Pythagoras. The augurs of Rome, and the emperor Augustus himself, practised it. During the later middle ages it was chiefly in the hands of gypsies, and was studied, like alchemy and astrology, by such philosophers as Albertus Magnus, Cardan, Roger Bacon, and Paracelsus. The church, which passed severe judgments on magical arts, tolerated chiromancy, only forbidding all alliance between it and astrology, and all interference of it with the doctrine of human liberty. A rationalistic view of chiromancy is that all actions, passions, and thoughts leave their traces on the body, and that from the conformation of the hand, its furrows, folds, colors, veins, hardness or softness, an experienced and skilful eye can determine the person's habits, social position, and the stronger tendencies of his character. The most important writers on the subject are Artemidorus (in the 2d century), Cocles (Bologna, 1504), Piccioli (Bergamo, 1578), De la Chambre (Paris, 1653-4), Prätorius (Jena, 1661-4), May (the Hague, 1665), Pompeji (Venice, 1680), Ingenbert (Frankfort, 1742), Peuschel (Leipsic, 1769), and especially the anonymous author of the *Grand jeu de société* (Paris, 1845), which contains an account of ancient and modern chiromancy.

CHIRON, in Greek mythology, the wisest of all the centaurs, reputed to be the son of Cronus (Saturn) and Philyra, born before the Argonautic expedition. He was taught by Apollo and Diana, and was skilled in hunting, gymnastics, botany, medicine, music, and the art of divining future events. He lived at the foot of Mt. Pelion, in Thessaly, and such was his fame for wisdom that almost all the noble youths of Greece resorted to his cave for instruction. Among his pupils were Hercules, Peleus, who was also his grandson, Nestor, Castor and Pollux, Ajax, Achilles, Ulysses, and Diomedes. When the other centaurs were about to kill his grandson Peleus, Chiron saved his life, and it was only by means of Chiron that Peleus was enabled to obtain his beloved Thetis for his wife. The Argonauts, on their expedition in quest of the golden fleece, stopped at the abode of Chiron, were kindly entertained by him, and received from him a chart of the constellations, which he made to assist them in their navigation. Hercules was one of his favorite pupils, but an arrow from his bow shot at another centaur unfortunately killed his beloved preceptor. Chiron was immortal; but when pierced by the arrow of Hercules, he gave up his immortality to Prometheus, and died.

CHISAGO, an E. county of Minnesota, separated from Wisconsin on the E. by the St. Croix river; area, 450 sq. m.; pop. in 1870, 4,358. It is watered by affluents of the St. Croix, and by Rush, Chisago, and other lakes. The surface is uneven and partly occupied by pine forests. The Lake Superior and Mississippi railroad passes through it. The chief produc-

tions in 1870 were 32,857 bushels of wheat, 13,603 of Indian corn, 39,596 of oats, 16,975 of potatoes, 6,242 tons of hay, and 100,975 lbs. of butter. There were 378 horses, 1,027 milch cows, 1,774 other cattle, 1,387 sheep, and 988 swine. Capital, Chisago City.

CHISHOLM, Caroline (Jones), an English philanthropist, born at Wootton, Northamptonshire, in 1810. In her 20th year she married an officer of the Indian army, with whom she proceeded to Madras, where she established a school for the orphans of British soldiers. In 1838 she removed with Capt. Chisholm to Australia, and at Sydney she found a new call upon her exertions in the numerous young women landed there in destitution from emigrant ships. Having obtained an old building for an asylum, she trained and instructed the girls while under her charge, and found situations for both men and women. Between 1841 and 1845 she procured employment for 11,000 persons, to whom she had lent in small sums £1,200, the whole of which, excepting £16, was repaid to her. She returned to England in 1846, with thanks and a testimonial from distinguished citizens of Sydney; instituted the family colonization society, by which passage money was paid in weekly instalments; and in many ways planned to relieve emigrants of the poorer classes. She went back to Australia in 1854, but returned to England in 1866. During her first residence in Australia she published "Voluntary Information of the People of New South Wales."

CHISWICK, a village and parish of Middlesex, England, 5 m. W. of Hyde Park corner, London, on the left bank of the Thames; pop. in 1871, 8,508. It is one of the most charming suburbs of London, and contains handsome villas, the gardens of the London horticultural society, and Chiswick house, a celebrated suburban villa belonging to the duke of Devonshire, where Fox and Canning died, and where Paxton, the architect of the crystal palace of 1851, was employed previous to being transferred to the duke's country seat at Chatsworth.

CHITON, a genus of marine animals, generally arranged as a family of gasteropod mollusks. The shell is composed of eight transverse im-

Chiton squamosus and *C. spinosus*.

bricated plates, attached to a thick mantle which forms an expanded margin around the body; the border of the mantle is either bare or covered with minute plates, hairs, or spines.

The animal has a broad creeping disk, like the limpet; no eyes, no tentacles, but a long linear tongue in a cartilaginous proboscis, well armed with teeth. Heart central, and elongated like the dorsal vessel in annelids; sexes united; intestine straight, and anal orifice posterior and median. The name is derived from the resemblance of the shell to a coat of mail (Gr. *χιτών*). More than 250 species are known, occurring in all climates, throughout the world; most abundant on rocks at low water, but some live at a depth of 100 fathoms; they have existed from the Silurian period. It is an aberrant form of mollusk, and some are inclined to place it rather among articulate, or at least as a form leading to the articulate. Some of the tropical species grow to a large size, and their muscular foot is often used as food.

CHITORE, Chittor, Chetore, or Chittorgurh, a town of British India, formerly the capital of the rajahship of Odeypoor, situated on the river

Pillar of Victory.

Biruch or Beris, over which is a bridge of nine arches, 36 m. N. W. of Neemutch, and 100 m. S. of Nusseerabad; lat. 24° 52' N., lon. 74° 41' E. It contains three large temples, and a remarkable structure called the pillar of victory, erected in 1439 to commemorate the defeat of the combined armies of Malwa and Guzerat by Rana Khumbo, who governed Odeypoor from 1418 to 1468. It is 122 ft. high, covered with mythological sculptures in white marble, and has nine stories, the whole surmounted by a cupola. There are several large reservoirs, but the most important feature of the town is its fortress, built on a high scarped rock, and considered a work of great strength. Its walls, though enclosing only an irregular and not very extensive area, are said to describe a circuit of 12 m. Most of the notable buildings are within this enclosure. After undergoing several changes of rulers, Chitore was stormed by the emperor Akbar in 1568, when the Rajpoot garrison, 8,000 strong, after exhausting every means of resistance and all hope of relief, sacrificed their wives and children, and

rushing upon the enemy perished almost to a man. It was afterward recovered by the Rajpoots, was captured by Aurungzebe about 1676, and reverted to the Rajpoots on the dismemberment of the empire of Delhi, toward the close of the 18th century.

CHITTAGONG, or **Chittagaon**. **I.** A district of British India, lying beyond the Ganges, but included in the province of Bengal, bounded N. by independent Tiperah, E. by Burmah and Aracan, S. by Aracan, and W. by the bay of Bengal, between lat. $20^{\circ} 45'$ and $23^{\circ} 25' N.$, lon. $91^{\circ} 32'$ and $93^{\circ} E.$; length from N. to S., 185 m.; greatest breadth, 80 m.; area, exclusive of wooded hill tracts on the E. frontier, about 3,000 sq. m.; pop. about 1,000,000. It has several rivers, the chief of which is the Chittagong, which is formed by the junction of the Kurrumfoolee and the Chingree, and flows into the bay of Bengal. A large part of the surface is occupied by portions of the great mountain range extending from Assam S. to Cape Negrais, and several of the summits in this district have an elevation of from 3,000 to 8,000 ft. above the sea. The climate is similar to that of Bengal, except that the rainy season is longer. The agricultural products, most of which are obtained with little labor, are rice, sugar, hemp, oats, tobacco, mustard, betel nut, indigo, ginger, and coffee. The exports are timber, salt, coarse cloth, and elephants, of which many are annually caught here for the government. The inhabitants are aborigines resembling the Burmese, Bengalese, and Mughls; the Mohammedans outnumber the Hindoos in the proportion of 3 to 2. The mountains are the retreat of several wild tribes whom no government has ever reduced to subjection. During the wars between the Moguls and Afghans, Chittagong was held by Aracan, from which it was conquered by Aurungzebe toward the close of the 17th century. It was ceded to the East India company by the nawaub of Bengal in 1760, and has been included in the government of Aracan since the company acquired the latter from Burmah in 1826. **II.** The capital of the above described district (sometimes called Islamabad), an unhealthy, declining place, on the river of the same name, 212 m. E. of Calcutta, and 160 m. N. of Akyab. It was once important for trade and ship building, but rice, which it once largely exported, is now got more cheaply in the ports of Aracan, and its ship building business has been transferred to Maulmain in Tenasserim.

CHITTELDRÖG, or **Chitradurg** (anc. *Sitala Durga*, "the spotted castle"), a town of British India, in the province of Mysore, capital of a district of the same name, 280 m. W. N. W. of Madras, 125 N. of Seringapatam, and 70 m. S. of Bellary; lat. $14^{\circ} 14' N.$, lon. $76^{\circ} 27' E.$ It is situated in a fertile plain, noted for the excellence and variety of its fruits. The town is neither large nor populous, but was formerly one of the strongest places in India. Its fortress, crowning a high rock at the back of the

town, is one of the finest specimens of rock fortification in S. Hindostan. Walls of solid masonry encircle it several times with many intricate windings, and completely guard every accessible point. The ascent is performed partly by the aid of notches cut in the rock. Hyder Ali besieged the town in 1776, at which time it was held by a warlike and fanatic tribe called the Beders. During the siege they erected upon the highest part of the citadel a temple to the goddess of destruction, upon whose propitiation they thought their safety to depend, and every week, after solemn rites performed before her image, they rushed forth with desperate frenzy to procure human heads to lay at her shrine. These sallies were seldom unsuccessful, and when the place was finally taken 2,000 heads were found piled before the temple. Hyder obtained possession of the town by treachery in 1779. In the neighborhood of Chitteldroog are some curious caverns, supposed to have been used as dwellings by devotees of Siva.

CHITTENDEN, a N. W. county of Vermont, bounded W. by Lake Champlain; area, 517 sq. m.; pop. in 1870, 36,480. It is drained by Lamoille and Onion rivers, which afford valuable water power. Near the lake the surface is generally level, but toward the east it becomes rough and in some places mountainous. Nearly all the land is fertile, suitable for grazing, or capable of producing corn, potatoes, &c. The Vermont Central and the Rutland and Burlington railroads traverse the county. The chief productions in 1870 were 44,426 bushels of wheat, 163,597 of Indian corn, 286,615 of oats, 333,858 of potatoes, 82,629 tons of hay, 1,374,387 lbs. of cheese, 1,761,543 of butter, 87,256 of wool, and 426,726 of maple sugar. There were 4,977 horses, 21,941 milch cows, 8,919 other cattle, 17,041 sheep, and 4,809 swine. There were 2 manufactories of boxes, 7 of cheese, 7 of furniture, 1 of boats, 4 of sashes, doors, and blinds, 3 of woollen goods, 6 flour mills, 6 planing mills, 23 saw mills, 10 manufactories of carriages and wagons, 1 of cotton goods, 3 of iron castings, 2 of machinery, 3 of patent medicines, 5 tanneries, and 4 currying establishments. Capital, Burlington.

CHITTENDEN. **I.** Thomas, the first governor of Vermont, born in East Guilford, Conn., Jan. 6, 1730, died at Williston, Chittenden co., Vt., Aug. 25, 1797. He represented Salisbury, Conn., in the legislature of that state for several years, and was also a colonel of militia and a justice of the peace. In May, 1774, he removed with his family to Vermont, and during the revolutionary war was repeatedly obliged to change his residence. He was a member of the convention at Dorset, in September, 1776, for the purpose of taking into consideration the expediency of declaring Vermont an independent state. He was one of the committee that drafted the Vermont declaration of independence, and was also one of the committee appointed to petition congress to acknowledge the independence of the state. He

was a leading member of the convention at Windsor, July 2, 1777, which formed the first constitution of Vermont, and was president of the council of safety, which was vested with all the powers of government, executive, legislative, and judicial, to be exercised until the government should be organized under the constitution. In 1778 he was elected governor of Vermont, which office he held with the exception of one year till his death. A memoir of him, with a history of the constitution of Vermont during his administration, by Daniel Chipman, was published in 1849. **II. Martin**, son of the preceding, born at Salisbury, Conn., March 12, 1766, died at Williston, Vt., Sept. 5, 1840. He graduated at Dartmouth college in 1789, and commenced farming at Jericho, Chittenden co.; was a member of the convention in Vermont that adopted the constitution of the United States; was appointed side judge of the county court, and reelected for three years, and then appointed chief judge of the same court, and reelected seven years successively. In 1803 he was elected member of congress, and received four reelections. From 1813 to 1815 he was governor of Vermont.

CHITTY, Joseph, an English lawyer, born in 1776, died in 1841. He was eminent in his day as a special pleader, but has a more enduring fame as a writer of legal text books, indispensable to students and practitioners in English law. His chief works are a "Treatise on the Parties to Actions and to Pleadings" (1809); "Treatise on the Law of Nations relative to the Legal Effects of War on the Commerce of Belligerents and Neutrals, and on Orders in Council in Licenses" (1812); a "Practical Treatise on the Criminal Law" (4 vols., 1816); and a "Synopsis of Practice in the King's Bench and Common Pleas" (1816).

CHIUSA, an Italian word for a narrow mountain pass, as for instance the Chiusa dell' Adige, near Verona, and the name of a number of localities in Italy, including a Benedictine abbey, San Michele della Chiusa, on Monte Pirchiriano, near a hamlet called La Chiusa, about 11 m. N. E. of Turin, now used as a hospice and as the burial place of the royal family. The following are the largest towns of the name. **I. Chiusa di Pesio**, in the province and 7 m. S. E. of Cuneo, on the left bank of the Pesio; pop. about 6,500. It is well built, and contains ruins of the old castle of Mirabella. Silk and glass, and particularly mirrors, are extensively manufactured here. A continuation of the Roman Æmilian way passed in this vicinity. **II. Chiusa Selafani**, Sicily, in the province and 30 m. S. by W. of Palermo; pop. about 7,000. It was founded about 1320 by Matteo Selafani, count of Aderno. The prominent buildings are the parish church, with pointed arches resting on stunted columns, and a Capuchin convent with a fine picture of the "Adoration of the Magi." Precious metals and iron are said to have been found here in ancient times, and jasper and especially

agates still abound. On a rock 2 m. S. W. of Chiusa is the village of Giuliana, with a castle and fortification constructed by Frederick II. of Aragon.

CHIUSI (the *Camars* of the Etruscans, and *Clusium* of the Romans), a city of Italy, in the province and 38 m. S. E. of Siena, situated

Chiusi.

on a hill in the valley of the Chiana; pop. about 4,200. It was the ancient capital of King Porsena. Its decline was caused in the 11th century by the accumulation of the waters of the Chiana, which changed the surrounding valley into a pestilential marsh. Dante (*Paradiso*, xvi.) describes its depopulation. The valley was drained by works completed in 1823, and Chiusi is now the seat of a bishopric, has a beautiful cathedral, and several rich museums of Etruscan and Roman antiquities. On a mountain E. of the town stands the monastery Sagra di San Michele, one of the most notable religious structures in central Italy. (See *CLUSIUM*.)

CHIVALRY (Fr. *chevalerie*, riders of horses), an institution forming the special characteristic of European civilization in the middle ages. It flourished from about the beginning of the 10th century to the end of the 15th; a century more for its rise and another for its decline will include the period of its existence as an organized institution. Almost every feature of chivalry has existed in all ages and among all peoples except utter savages. Its germs, especially in its avowed relations to the female sex, existed in the German forests long before the Christian era, although they remained undeveloped until after the destruction of the Roman empire and the establishment upon its ruins of the states of modern Europe. During the period between the 5th and 10th centuries there existed in that part of Europe which had been a portion of the Roman empire scarcely a trace of culture except in the cloisters, scarcely any safety to person or property except such

as had come into the possession or under the direct protection of the church. Elsewhere the strong hand was the only law. In time the spirit of the church began to spread beyond the cloister, and here and there a brave and humane man would take upon himself the task of protecting the weak and redressing the wrongs of the injured. Women, being the weakest and most liable to suffer wrong, naturally first claimed this protection; and so to courage was added courtesy and refinement, and at least in theory chastity and temperance, as essential to the character of these self-appointed champions. These naturally associated themselves for mutual aid and protection. The church was eager to aid and be aided by this growing institution; and so it early took upon itself a religious form. France was the country in which the new civilization first gained strength; and here the institution of chivalry first took form. From France the institution spread to England, Spain, southern Germany, and southern Italy. Ethnologically the order belonged to that branch of the Teutonic family which had overrun these countries, which then mainly constituted Christendom. The crusades suddenly melted all Christendom into a sort of body politic, of which chivalry and the church became the notable characteristics. The decrees of the famous council of Clermont (1095), which sanctioned the first crusade, indicate the importance which the institution of chivalry had then attained. This council, after confirming and extending the "truce of God" (see TRUCE OF GOD), formally recognized the institution of chivalry by decreeing "that every person of noble birth, on attaining 12 years of age, should take a solemn oath before the bishop of his diocese to defend to the uttermost the oppressed, the widows and orphans; that women of noble birth, both married and single, should enjoy his special care; and that nothing should be wanting in him to render travelling safe and to destroy the evils of tyranny." In this decree all the amenities of chivalry were sanctioned by the civil and ecclesiastical power. It will be noted that, unlike the church, which in theory at least recognizes the right of all men to all her privileges and immunities, chivalry had nothing to do with any except those of gentle birth; but by the decree of the council every male person of such birth was from childhood enrolled as a candidate for the order. The training of the chevaliers, or, as we usually style them, the knights, grew into an elaborate system of education, admirably adapted to its purpose. Except for those who should enter the church, there was no career but that of arms. Every noble youth was to be trained as a soldier. This training was seldom carried on at home. Youths of the highest rank were usually educated at the court of the sovereign or at the castle of some neighboring lord. The importance of a noble was measured to a great extent by the number of his followers. The

castle of every noble of wealth and repute became a kind of school for the training of the sons of his friends and neighbors. The education of the boy began at the age of 8 or 10. He was taught the rules of courtesy and the mysteries of hunting, and trained in riding and the use of the weapons fitting his age and strength, and was styled a valet or page. At the age of 14 he was held fit to become an esquire or squire, that is, a shield-bearer, and to accompany his master to the battle field, rather as a spectator than as a combatant. At 21, and sometimes earlier, he might become a knight. The full induction to the order was sometimes made on the battle field, when the forms were few and brief; but when the rank of the candidate and the circumstances permitted, the induction was accompanied by elaborate religious rites, at the close of which he received from the investing knight the *accolade*, or three blows with the flat of the sword, with the words, "In the name of God, of St. Michael, and of St. George, I dub thee knight; be brave, bold, and loyal." Originally every knight had the right to confer the dignity, but in course of time this came to be restricted to sovereign princes, and to the commander of a royal army in the field. Only a small portion of the squires became knights, although all were entitled to claim the honor. The knight required several horses, a squire or two, and a number of attendants. Unless he had considerable estates, or had won renown for valor and skill sufficient to gain for him a large guerdon, he would not be able to defray all these expenses; and so most of them remained squires, attached to the service of some prince or baron, or not unfrequently in a state of independence, hiring out their own military services, and those of such men-at-arms as they could gather around them, to any one who was able to pay their price. These squires must be distinguished from those others who were the attendants of knights, and undergoing training for the order of knighthood. Not a few of the stoutest soldiers of chivalry were never more than squires, and a brave squire not unfrequently had under his control a large band of followers. He was entitled to lead these to the field under his own banner. The especial standard of a squire was the pennoncel, a long, narrow triangular flag, in distinction from the forked or swallow-tailed ensign of a knight, which resembled two pennoncels united at the base or flag staff, and the square pennon of the barons or great feudatories. Every knight had the right to ask of his sovereign or immediate commander in the field the privilege to use the square pennon. This request was granted if he had won renown at arms, and had a sufficient number of followers, which later became fixed at not less than 30 lances, with the requisite number of men-at-arms. The commander took the forked flag, cut off the points, and returned it thus transformed into the square pennon. The knight then became a

knight banneret, a degree which has sometimes, though improperly, been considered a separate order of chivalry; but it was really only a grade in the same rank, merely giving military precedence over the other knights, who in time came to be designated as *bas-chevaliers*, or bachelors.—The strict definition of a knight or chevalier is one who fights on horseback; the Germans called him a *Ritter*, or rider. His proper arms were the lance, the two-handed sword, sometimes a battle axe or mace, and a short sharp dagger. He was clad in complete armor, and his horse was also protected. When mounted and armed, he was almost invulnerable against any opponent of the time, except one equally armed and armored. His coat of mail was proof against any missile but the shaft from the formidable longbow, used only by English archers. The ineffective weapons of the common European soldiers could not touch him; the keen scimitars of the Saracens, which would sheer off a limb or a head, were useless against him. A score of knights could ride unharmed through a host of common soldiers. So the crusaders found it against the Saracens, and the Spanish conquistadors against the Aztecs. But the knight, once unhorsed and thrown upon his back, was as helpless as a turtle in the same position. He could not even gain his feet without assistance, and no matter of what proof his armor was, there must be some joint or opening through which a dagger could penetrate, or it might be battered in with a club or stone. The ideal knight of the middle ages was a man trained to the use of arms, imbued with generous sentiments, and possessed of all the humane virtues. He was ideally brave and courteous, chaste and temperate, generous and pious. Guizot has digested into 25 articles the various knightly oaths as administered at different periods. The man who even measurably observed them might fairly be considered a secular saint. But the actual knight of chivalry, even taking into account only its most illustrious examples, fell far short of this standard. The exaggerated devotion with which he was supposed to regard his lady love, which should, as an old writer phrases it, “defend him from pride and the other deadly sins of anger, envy, sloth, and gluttony, and render it impossible that his conduct should ever be stained with the vice of incontinence,” became in effect only a veil to cover the grossest amatory license. The morals of the age of chivalry, tried by any modern standard, were gross and licentious. The romances of chivalry, which must be accepted as a fair picture of the social morals of the time, are mostly unfit for reading. Chivalry indeed bound the aristocracy together, and caused the knights and squires of even hostile and warring nations to sympathize with each other, and observe many amenities of warfare. But the chivalry who had to-day fought with each other were ready to-morrow to unite to exterminate a squalid

peasantry who had been driven to insurrection by intolerable outrage. Here and there, indeed, a knight or noble would protect his vassals, just as he would protect his horse or hound; but that the common people had any intrinsic rights as against the will of a noble was an idea which never entered into the code of chivalry. War was the main business of a knight; but in the most turbulent times men cannot be always fighting. The chase, tournaments, jousts, and other games of mimic warfare were the occupations and amusements of chivalry. The tournament was the most elaborate form of these martial games. Tournaments were held under the auspices of some sovereign or great noble, and were attended by ladies, who bestowed the prizes won by the successful combatants. The combats, whether between individuals or companies of knights, were conducted in accordance with fixed rules, which no one might violate. The jousts and passages of arms were merely less formal combats. They might be simply a duel to decide a private quarrel, or a knight, merely to display his prowess, would challenge all comers to encounter him. A class known as knights errant arose, whose special avocation was to encounter any opponent who might present himself. They were the chivalric representatives of the champions in the modern prize ring. The aspects of chivalry were considerably modified by the circumstances of the different countries in which the institution existed. In Spain the chief business of the knights was to fight against the Moors, and hence hatred and contempt of infidels came to be the marked characteristic of Spanish chivalry. In England the predominance of the order was kept in check by the yeomen and archers, who formed a military body unknown in France. During the crusades arose the great military orders, semi-monastic in their character, such as the knights templars and the hospitalers or knights of St. John, formed for the defence of the Holy Land; and later the Teutonic knights, who afterward undertook to exterminate heathenism in the north of Europe.—The institution of chivalry sank gradually under a combination of physical and moral causes, the changes introduced into the art of war, and the equally great changes in the social and political condition of Europe. Society advanced as the power of the great nobles and feudatories declined. Many of the nobles had sold their estates to fit themselves out for the crusades, and lost their lives in the Holy Land. Those who returned found that towns had sprung up near their castles, filled with burghers ready and able to defend by force of arms the privileges which they had bought or wrested from their feudal lords. Slowly it began to be discovered that infantry could be so armed and manœuvred as to withstand the shock of cavalry. At the battle of Morat (1476), the Burgundian chivalry, the finest in Europe, led by

Charles the Bold, were shattered against the ranks of the Swiss pikemen, and the old superiority of the knights disappeared. When a few years later firearms were so improved as to become weapons of precision, the value of the knightly armor was wholly destroyed. An arquebuser was more than a match for a knight in the field. The knights laid aside their heavy mail, their long lances, and two-handed swords, and chivalry as a special military organization disappeared. By the end of the 16th century chivalry as an institution had disappeared. The descendants of the French knights became courtiers, more and more dissolute and effeminate from generation to generation, until the very name of noble was swept away by the revolution. Δ The place of the institution of chivalry in the world's history is clear. It was good in that it partially took the place of something much worse. If men must fight, it is better that the horrors of war should be ameliorated by some rules of amenity. The benefits which chivalry conferred upon the world were many and great, and cannot be questioned. For the rest, it is safe to affirm that the general condition of society in the best parts of Christendom, during the best days of chivalry, was worse than it now is in the worst parts of the civilized world.—The literature connected with chivalry runs through all the history, fable, and poetry of the period of its existence. Among the most important modern works relating to it are: *Mémoires sur l'ancienne chevalerie*, by De la Curne de St. Palaye (Paris, 1759-'80); *Collection historique des ordres de chevalerie*, by Perrot (1836); *Dictionnaire historique des ordres de chevalerie*, by Gourdon de Genouillac (1853); *Ritterzeit und Ritterwesen*, by Büsching (Leipsic, 1823); *Ritterwesen und die Templer, Johanniter, etc.*, by Weber (Stuttgart, 1822-'4); especially the very complete *Geschichte des Ritterwesens*, by Reibisch (Stuttgart, 1842); the "History of Chivalry," by Mills (London, 1825); "Chivalry and the Crusades," by G. P. R. James (London, 1825, and often reprinted). Sir Walter Scott's article "Chivalry," in the "Encyclopædia Britannica," almost a volume in itself, gives a graphic sketch of the character of the institution; and several of his novels, notably "The Talisman," "Ivanhoe," "Count Robert of Paris," "Castle Dangerous," and "Quentin Durward," contain vivid pictures of the manners and habits which prevailed during the age of chivalry.

CHIVASSO, or **Chivas** (anc. *Clavissium*), a city of Italy, situated in a fertile plain on the left bank of the Po, on the railway from Turin to Ticino, in the province and 14 m. N. E. of Turin; pop. about 5,000. It has a church dating from 1425, five convents, and the ruins of an ancient castle or palace of the counts of Montferrat. Its trade is chiefly in grain and cattle; it is also celebrated for its lampreys. For a long period it was regarded as the key of Piedmont, and was well fortified, but its de-

fences were destroyed by the French in 1804. A few miles below, on the other side of the Po, are the remains of the ancient city of Industria, discovered in 1745.

CHLADNI, **Ernst Florens Friedrich**, a German physicist, born in Wittenberg, Nov. 30, 1756, died in Breslau, April 4, 1827. Educated for the profession of law, he early left its practice and gave himself to the science of acoustics. He was especially successful in experimenting upon the velocity of sound in various bodies, gaseous and solid; and even more so in experiments and calculations on the movements of plates of glass when in acoustic vibration. He also distinguished himself by being the first scientific man who defended the popular opinion of the fall of solid bodies from the sky. Chladni was the inventor of the musical instruments called the euphonon and the clavicylinder. His principal works are: *Entdeckungen über die Theorie des Klanges* (Leipsic, 1787); *Die Akustik* (Leipsic 1802; translated into French, *Traité d'acoustique*, Paris, 1809); *Ueber Feuermeteore* (Vienna, 1819); *Neue Beiträge zur Akustik* (Leipsic, 1817); and *Beiträge zur Akustik und zur Lehre vom Instrumentalbau* (Leipsic, 1822). (See ACOUSTICS.)

CHLAMYPHORUS, or **Chlamydophorus**, a name first given by Dr. Harlan to a small mammal, a native of Chili, which seems to form a connecting link between the edentates and the insectivora; it is placed, however, among the former, and by Gray near the armadillo; its native name is *pichiciago*. It is about 5½ inches long, the top of the head, back, and hind quarters being covered with 24 rows of plates, of a consistence greater than that of leather; at the end of the body this covering is suddenly curved downward, so that the creature looks as if the body had been here chopped off; hence its name *C. truncatus*. The lower parts are covered with a soft fur, like that of the mole; the head is conical; molar teeth 3; most of the ribs, as in birds, are united to the breast bone without cartilages; the tail is short, strong, curved

Chlamyphorus.

beneath the body, and evidently used for removing backward the earth accumulated between the limbs during its burrowing; fore limbs strong and mole-like for digging. It lives

under ground like the mole, feeding on worms and subterranean insects; the eyes are very small. This curious animal resembles the mole in its form, subterranean habits, and fore limbs; it comes near the sloths in the teeth, near the armadillo in its covering and the general characters of the skeleton, and near the monotremata and birds in the breast bone, ribs, and open pelvis.

CHLAMYS (Gr. *χλαμύς*, a scarf), an outer garment of the ancient Greeks and of the oriental races. It somewhat resembled the *paludamentum* of the Romans, and in the reigns of some of the later emperors was adopted by them. It was a woollen garment, and differed from the blanket, *ἱμάτιον*, which was the usual dress of the male sex among the Hellenic races, in being much smaller, of a finer material, often variegated in brilliant colors, and otherwise richly ornamented. It was also, in its usual form, oblong instead of square, being twice as long as it was wide; but it was sometimes increased in volume by the addition of two gores, or wings, in the shape of obtuse-angled triangles, sewn on the long sides with the apices upward. With this improvement it was known as the Macedonian or Thessalian chlamys. The usual mode of wearing the chlamys was to fasten the corners of the shortest side by means of a clasp (*fíbula*, *περόνη*) on the middle of the chest, when the garment fell down over the back to the knees, or on the right shoulder, when it hung over the left arm and side, much after the fashion of the short cloak of the Elizabethan costume in England, commonly, though improperly, supposed to be of Spanish origin. In the latter mode it was often worn over armor as an ornament or insignia of dignity, especially by generals and officers of superior rank. The chlamys worn by boys was ordinarily yellow, the military chlamys scarlet; and it was remarked afterward as of evil omen, that on the fatal day of Carrhæ Crassus wore a dark-colored chlamys or paludamentum. The chlamys of women had often a rich fringe or border, and was many-colored and richly embroidered. It was not unusual to twist the chlamys about the arm, so as to serve as a shield; as was done by Alcibiades, when he died fighting against his murderers.

CHLOPICKI, Józef, a Polish general and dictator, born in March, 1772, died at Krzeszowice, Sept. 30, 1854. At an early age he entered the military service, and distinguished himself in the war for independence under Kosciuszko. After the surrender of Warsaw to the Russians (1794) he retired, went to France, and enlisted in the service of the Cisalpine republic, under the command of Gen. Dombrowski. When in 1806 Dombrowski and Wybicki called the Polish nation to arms, under the protection of Napoleon, promising the return of Kosciuszko, Chlopicki, returned to his country, and served with distinction in the great battles of Eylau and Friedland (1807) in the East Prussian campaign. From 1808 to 1811 he fought in Spain,

taking part in the siege of Saragossa, and in the protracted war in Aragon, Cataloña, and Valencia, where he defeated Palafox, Mina, and others. The campaign against Russia in 1812 promised the restoration of Poland, and he gained new distinction in the battles of Smolensk and on the Moskva, where he was wounded. He then followed the retreating French army, but not having received the promotion to which he considered himself entitled, he resigned, and was living in retirement when the armies of the coalition entered Paris in 1814. On the invitation of Alexander of Russia, who assumed the title of king of Poland, and gave the new kingdom a constitution and a national government, he entered the ranks of the new Polish army as general of division; but the wild and capricious temper of its chief commander, the grand duke Constantine, soon caused him to retire. After the night of Nov. 29-30, 1830, which expelled Constantine from Warsaw, Chlopicki was called upon by the general voice to put himself at the head of the nation; but having no faith in the success of the insurrection, he hesitatingly joined the provisional council of administration, and could hardly be persuaded to accept the dictatorship, which he assumed, however (Dec. 5), on the field of Mars, but with the declaration that he would resign his dignity to the national diet immediately after the meeting of that body. But the diet confirmed him in his office, one voice only opposing. He maintained order and discipline; but his temporizing movements, his fear of failure, his strict observance of the narrow limits of the kingdom as created by the treaty of Vienna in 1815, and his negotiations with the emperor, proved to the patriots that they had fallen into error in the choice of a leader. On Jan. 23, 1831, Chlopicki laid down his office and his military command, and proved his patriotism after the declaration of independence by serving in the battles of Wawer and Grochów (Feb. 19 and 25), as a common soldier and adviser of the new commander-in-chief, Prince Radziwill. In the second battle of Grochow he led a regiment against the Russians; three horses had already been shot under him, yet he was still advancing, when a double wound compelled him to retire, and checked the Polish advance. To restore his health he went to Cracow, where he remained after the fall of Poland, under surveillance, being but seldom allowed to leave the place.

CHLORAL (synonymes, trichlormethyl, hydrocarbon oxide, trichloraldehyde, trichloroacetyl, oxide hydrate), a chemical compound first obtained by Liebig in 1831 by the action of chlorine upon absolute alcohol. The name is composed of the first syllables of the words chlorine and alcohol. Although Liebig first prepared chloral, we are chiefly indebted to Dumas for a knowledge of its properties and constitution. It is obtained by passing dry chlorine gas through absolute alcohol as long as it is absorbed, during many hours, keeping the vessel cool

in the early stages of the operation; later the temperature must be gradually raised until the liquid boils. The reaction is represented by the formula $C_2H_6O + 8 Cl = C_2HCl_3 + 5HCl$. If dilute alcohol be employed instead of the absolute, no chloral is formed, but in its stead aldehyde, acetic acid, and hydrochloric acid; hence the necessity of using absolute alcohol. It is also difficult to prevent the formation of other compounds, especially chloride of carbon, which serve to contaminate the chloral and render its administration dangerous. Chloral is also produced by the direct action of chlorine on aldehyde, also on starch or sugar.—Chloral is a limpid, colorless, oily liquid, with a fatty taste and a strong caustic smell, producing lachrymation. Its specific gravity is 1.502, and it boils at 95° C., and can be distilled unchanged. It dissolves sulphur, phosphorus, bromine, and iodine, and combines directly with water to form a hydrate. A little chloral put into a moist flask deposits star-shaped crystals of the hydrate on the sides. It changes after a time into a porcelain-like mass called metachloral, which is insoluble, though isomeric with the liquid form. It can be reconverted into chloral by distillation. The white metachloral is insoluble in alcohol and ether, as well as in water, but by contact with water it is gradually converted into the crystallized hydrate of chloral. Fuming nitric acid converts chloral into trichloroacetic acid. An alcoholic solution of potash converts chloral into formiate of potash and chloroform. Chloral is closely allied to aldehyde; it reduces silver from the ammonia nitrate solution, and forms crystalline compounds with ammonia and the acid sulphites of the alkalis. Nascent hydrogen converts it into aldehyde. If chloral be mixed with one equivalent of alcohol, white transparent hygroscopic crystals of chloral-alcoholate are formed. This compound has different properties from the hydrate of chloral, and ought not to be mistaken for it. Chloral combined with one equivalent of water forms a crystalline mass, now popularly known under the name of chloral hydrate. According to Dr. Squibb, when the water of hydration is in excess, or when solid compounds of hydrate of chloral and water are put up, the substance is deliquescent, or even melts in warm weather, and a very slight excess of water manifests itself very soon by some degree of deliquescence. Whether in a cake or crystal, it is now very generally put up slightly deficient in water of hydration; that is, the chloral is not fully saturated to a hydrate, which gives the best product for preservation. Accurately hydrated chloral crystallizes at about 48° to 49° C. (118.4° to 120.2° F.). A little ammonia may be added to prevent acid reaction, and all acid hydrate of chloral should be rejected. The hydrate of chloral is readily dissolved by water, alcohol, ether, oil of turpentine, benzole, bisulphide of carbon, and the fixed oils. When equal parts of camphor in small pieces and hydrate of

chloral in crystals are allowed to stand in a flask, they form a clear solution. The analysis of chloral hydrate is accomplished by measuring in a graduated tube the amount of chloroform liberated by a given quantity of potash.—The enormous production of chloral hydrate has led to an investigation of its possible application in the arts and of uses for the incidental products accompanying its preparation. The precious metals are easily reduced by chloral hydrate and caustic alkalis. A large quantity of hydrochloric ether appears as a by-product in the manufacture of chloral, and is applied to the preparation of ethyl ammonias. A mixture of hydrate of chloral with three times its weight of fuming nitric acid is allowed to stand in the direct sunlight for three or four days until red fumes no longer appear; it is then distilled at a temperature of 194° C., and the product is found to be pure trichloroacetic acid.—Chloral hydrate was brought forward as an anæsthetic and hypnotic by Dr. Otto Liebreich in 1869. In the presence of alkalis chloral hydrate is decomposed into chloroform and formic acid; the latter unites with the alkali. The decomposition is supposed by Liebreich to take place in the blood, and the chloroform which is thus set free acts in the usual manner. This is almost the only example of an *à priori* discovery of a useful drug, and it is therefore to be regretted that the chemical evidence of such a transformation as that just indicated actually taking place in the blood is not more complete. Chloral hydrate, or as it is very frequently called chloral, has proved to be a valuable addition to the materia medica, although it cannot replace chloroform or ether as a surgical anæsthetic. It produces when acting favorably a quiet and natural sleep, although in rare cases no effect is observed from ordinary doses, and in some instances delirium arises from it. The average dose is from 15 to 30 grains. More than 30 grains at once has sometimes produced alarming symptoms. Death has resulted from still larger doses. It is a drug which should always be administered with caution, even in small doses. It is used to procure sleep in wakefulness from various causes and in many nervous diseases, as insanity, delirium tremens, neuralgia, tetanus, and strychnia poisoning. It is said that the use of chloral as a narcotic without medical advice is becoming a not infrequent habit. Properly administered, it will produce sleep, diminish sensibility and irritation, relax spasmodic action, and contract the arterioles of the system. Improperly used, it will retard the pulse, alter the blood globules, lower the temperature, and produce anæsthesia, muscular relaxation, and death. It should always be given largely diluted with water. The solutions of chloral hydrate in gum water, sirup, &c., undergo spontaneous decomposition, and become dangerous. The tinctures and anodynes kept on sale should be avoided. **CHLORALUM**, a trade name given by Prof. John Gamgee to the hydrated chloride of alu-

minum. It has been prepared as an antiseptic and disinfectant, and also for use in medicine.

CHLORATES, monobasic salts of chloric acid, HClO_3 , having the general formula MClO_3 . They are all soluble in water, and are transformed by heat into oxygen and a metallic chloride. The only one which possesses much importance in medicine or the arts is the potassium chlorate, which will be treated of with the salts of that metal.

CHLORIC ETHER, a name sometimes given to Dutch liquid, or bichloride of ethylene, and also erroneously applied to chloroform by its discoverer, Mr. Guthrie of Sackett's Harbor. At present it is applied to the preparation officially known as *spiritus chloroformi*, and composed, according to the "United States Dispensatory," of one measure of chloroform in between eight and nine of strong alcohol. A "strong chloric ether," which consisted of one part chloroform and two of alcohol, was used by Dr. John C. Warren of Boston by inhalation, as an anæsthetic in some 50 cases, and was supposed by him to be safer than chloroform. But in fact it possesses no advantages over the more commonly used anæsthetics, and it is at present but little employed for that purpose. The official preparation is a convenient one for the internal exhibition of chloroform, the effect of which is perhaps slightly modified by the stimulant action of the alcohol it contains. Half a dram to a dram may be given (diluted with water) as a dose. If the British preparation of chloric ether, which contains much less chloroform than the American, be used, the effect of the alcohol will be more marked than that of the chloroform. As a sedative and mild anodyne, chloric ether may be used with advantage in nervous restlessness, sleeplessness, and spasmodic affections, especially of the air passages.

CHLORIMETRY, a process chiefly designed to estimate the commercial value of bleaching powder. As this value depends upon the quantity of chlorine which can be liberated from the powders by an acid, Gay-Lussac proposed to estimate the value by measurement of the bulk of a solution of indigo of known strength which a given weight of the chloride is able to deprive of its blue color; and subsequently he determined the amount of available chlorine by the quantity of a standard solution of arsenious acid which could be converted by a known weight of the bleaching powder into arsenic acid. A still more convenient plan has been described by Graham. It depends upon the determination of the quantity of a ferrous salt which a given weight of bleaching powder, in the presence of an excess of acid, can convert into a ferric salt. To perform the operation, a tall narrow tube, called a burette, capable of holding 1,000 grains of water, and graduated into 100 equal parts from above downward, is employed.

CHLORINE (Gr. $\chi\lambda\omega\rho\acute{o}\varsigma$, green), a gaseous chemical element of yellowish green color, dis-

covered by Scheele in 1774, called dephlogisticated marine acid air, also oxidized muriatic acid, and first pronounced a simple body by Gay-Lussac and Thénard in 1809; a conclusion afterward confirmed by Sir Humphry Davy, who gave it the name it now bears. It occurs very abundantly disseminated over the earth, in salt brines in combination with sodium, with copper as atacamite, with potassium as sylvine, with silver as horn silver, with mercury as native calomel, and in smaller quantities with other minerals and volcanic gases. In the animal kingdom it is found in the gastric juice, in perspiration, &c., and among vegetables in marine plants. It is therefore one of the most abundant constituents of the earth. For laboratory use it can be conveniently prepared by heating in a retort a mixture composed of 10 parts by weight of common salt, 8 parts of manganese dioxide, and 24 parts of sulphuric acid, diluted with 12 parts of water. On a large scale it is usually prepared from hydrochloric acid, which in England is an incidental product. According to Weldon's process, the crude muriatic acid of the soda ash manufactory is decomposed by manganese dioxide, and the resulting manganese chloride is regenerated to be employed again. Deacon has modified the operation by conducting the muriatic acid directly from the condensing towers into a reverberatory furnace along with some oxygen of the air, over bricks saturated with salts of copper. Chlorine is liberated, and the reaction is said to be continuous, as the same copper salt will decompose an indefinite amount of the acid. Enormous quantities of chlorine are thus made in England, to be chiefly used in the manufacture of bleaching powders. Chlorine is a yellowish green, pungent, suffocating gas; specific gravity compared to air, 2.44, 36 times heavier than hydrogen. Under four atmospheres of pressure it can be condensed to a yellow limpid liquid of specific gravity 1.33. Copper, previously heated, burns readily in chlorine; arsenic, antimony, and phosphorus ignite spontaneously. A lighted candle gives off copious volumes of smoke and is soon extinguished; and ignited charcoal also ceases to burn on account of the weak affinity of carbon for chlorine; but hydrogen gas burns readily in chlorine, producing effects similar to those attained by the oxyhydrogen blowpipe. A piece of paper previously saturated with turpentine bursts into flame when plunged into a jar of chlorine gas. The affinity of chlorine for hydrogen is so powerful that if the two gases be mixed in the dark and subsequently exposed to the solar rays, they unite with a loud explosion. The electric light, or burning magnesium, can be substituted for the sunlight in this experiment. Water at 60° F. absorbs twice its volume of chlorine gas; and if the mixture be exposed to cold, crystals of a hydrate of chlorine will form, which resemble ice excepting in crystalline form, and contain variable quantities of chlorine according to the circumstances of

their formation. This hydrate was employed by Faraday in his celebrated experiment of liquefying chlorine gas. Chlorine water is gradually decomposed in the light, oxygen gas being liberated, and hydrochloric acid formed. Schönbein has shown that spongy ruthenium will also liberate oxygen from chlorine water, the same as the sunlight. Chlorine decomposes steam; hence the hydrochloric acid fumes which issue from the crater of Mt. Vesuvius. It will also expel oxygen from many metallic bases at high temperatures. The bleaching properties of chlorine were early investigated by Berthollet, Mackintosh, and Tennant, and through their recommendation many thousand acres of land were restored to agricultural uses which had previously been devoted to bleacheries. (See BLEACHING POWDERS.) Chlorine is a most efficient agent in decomposing putrid and noxious vapors and gases, and it is largely employed as a disinfectant. In combination it is employed in medicine as a stimulant and antiseptic, also as a gargle in scarlatina, putrid sore throat, and in smallpox. When inhaled, it instantly produces great irritation in the trachea, which may prove fatal. The vapor of ether and alcohol affords some relief. The compound of chlorine with nitrogen is a thin yellow oil, somewhat resembling nitroglycerine, excessively explosive, especially in contact with grease or oil.—Chlorine unites with oxygen in various proportions to form anhydrides and acids. The acids are hypochlorous, chlorous, chloric, and perchloric. The salts of hypochlorous acid, called hypochlorites, possess bleaching properties. The salts of chloric acid are called chlorates, and are used in medicine and the arts. The most important is the potassium chlorate. The compound of chlorine with hydrogen, called hydrochloric acid, hydrogen chloride, and muriatic acid, is one of the most important chemical products known in the arts. (See HYDROCHLORIC ACID.)

CHLORODYNE, a name given to several secret preparations, the most important ingredients of which are chloroform, morphia, cannabis indica, capsicum, and hydrocyanic acid. Dangerous and even fatal results have followed its use, as might indeed be supposed from the activity of the substances which enter into its composition, and the uncertainty of its doses.

CHLOROFORM (synonymes, trichlormethane, dichlorinated methyl chloride, and perchloride of formyl), a transparent, colorless oily liquid, discovered in 1831 by Samuel Guthrie of Sackett's Harbor, N. Y., and described by him as "a spirituous solution of chloric ether." Liebig, in a note to an article on chloral, published in Poggendorff's *Annalen* for November, 1831, also mentions this compound under the name of chloride of carbon, and gives the method of its preparation. Soubeiran also discovered it independently of either of the above named chemists; and although his article appeared in the *Annales de physique et de chimie* for October, 1831, that number of the journal was not

printed until the commencement of the year 1832, owing to the disturbed state of affairs in France at that time, and it is evident that he was not acquainted with the properties of "bichloric ether," as he calls it, so early as October, 1831. The priority of discovery in Europe is undoubtedly due to Liebig, and the confusion has arisen from the antedating of the journal in which Soubeiran's article first appeared. There is no question, however, that Guthrie was the first person to prepare chloroform, and to him the honor of its discovery is manifestly due. It has been asserted that from the time of the discovery of chloroform by Guthrie until its application as an anæsthetic vapor, it remained a mere chemical curiosity. This is not correct. In 1831 Dr. Eli Ives, professor of the theory and practice of medicine in the medical institution of Yale college, employed chloroform in a case of difficult respiration, administering it actually by inhalation of its vapor; he afterward published the facts in the "American Journal of Science" for January, 1832. Later Dr. Nathan B. Ives employed it in asthma, and in other cases, reporting upon it favorably. The exact formula of chloroform was determined in 1835 by Dumas, who gave it its present name. It was at first regarded as formic anhydride, in which the whole of the oxygen is displaced by its equivalent amount of chlorine, and hence the name given to it by Dumas. It is now looked upon as methylic ether, in which two atoms of hydrogen are replaced by two atoms of chlorine, and its formula is CHCl_3 .—Dr. Simpson's original paper on chloroform was communicated to the medico-chirurgical society of Edinburgh, Nov. 10, 1847, and he states that Mr. Waldie first made known the liquid to him. The medical profession having been prepared by the success of etherization to receive any new anæsthetic, whenever properly verified, at once accepted chloroform, coming as it did from such high authority as that of the late Dr. Simpson, and the news of its revived application spread rapidly over the globe. Dr. Simpson at once communicated the results of his experiments to Dr. Charles T. Jackson of Boston, who successfully repeated the trials of its anæsthetic properties, Dec. 30, 1847, upon Charles A. Joy, at that time a pupil in his laboratory (now professor of chemistry in Columbia college, New York). The introduction of chloroform into the medical practice of the United States dates from this time, although Dr. Ives had strongly recommended it many years before. It would have been difficult to purchase an ounce of chloroform in the United States in 1847; at the present time (1873) the annual consumption in this country cannot fall much short of 100,000 lbs.—Chloroform can be obtained by the action of hypochlorite of lime (bleaching powders) upon numerous organic substances, such as wine alcohol, wood alcohol, acetone, salts of the acetates, volatile oils, acetic acid, tartaric acid, formic acid, oxalic acid, and other

bodies; but the only practicable method for its production on a large scale consists in the distillation of alcohol from chloride of lime. Six parts of chloride of lime, 24 parts of water, and one part of alcohol are mixed in a capacious still, and the temperature raised as rapidly as possible till it reaches 180° F. The distillation is then continued until about one part and a half has passed over; the products, consisting chiefly of chloroform, accompanied by water, collect in two layers in the receiver, the chloroform constituting the lower layer. It is decanted from the aqueous portion, and agitated with oil of vitriol in order to destroy traces of volatile oils which accompany it; by another rectification it is obtained in a state of purity. Chloroform is a colorless, volatile liquid, of high refracting power. It has a powerful and agreeable ethereal odor, and a sweet, penetrating taste. Alcohol and ether dissolve it in every proportion, but it is very sparingly soluble in water. Concentrated sulphuric acid has no action upon it, and even potassium does not occasion its decomposition. It is inflamed with difficulty, and burns with a greenish, somewhat smoky flame, producing hydrochloric acid as well as carbonic anhydride and water. By admixture with an alcoholic solution of potash it is decomposed, potassic chloride and formiate being produced. Chloroform freely dissolves sulphur, phosphorus, iodine, camphor, resins, gutta percha, caoutchouc, strychnia, morphia, quinia, and fatty bodies. The specific gravity of the liquid is 1.497, of its vapor 4.2; boiling point 142° F.; it remains liquid at 0° F., but can be solidified by sudden evaporation. Chloroform vapor passed over red-hot copper is partially converted into acetylene. Pure chloroform is decomposed by exposure to light and air; but in the dark it remains unaltered in a vessel only half filled with it.—The vapor of chloroform possesses the remarkable power of producing in the person who has respired it complete temporary insensibility to pain. It may be readily inhaled for this purpose by placing a small quantity of the liquid upon a sponge or a handkerchief, which is to be held before the mouth and nostrils; and it is now commonly employed for rendering patients insensible to pain during severe surgical operations. It is of great importance that the chloroform used for this purpose should be quite pure. In some cases it has been found after exposure to a strong light to have undergone spontaneous decomposition. It ought to communicate no color to oil of vitriol when agitated with it. The liquid itself should be free from color, and it should be perfectly destitute of any chlorous odor. When a few drops are allowed to evaporate on the hand no unpleasant odor should be left. At present chloroform is much more largely used than ether for the production by inhalation of surgical anæsthesia. It is generally admitted to have over ether the advantages of rapidity of action, convenience of administration, agreeableness of odor,

and less subsequent nausea. These advantages, however, in the opinion of many physicians in various parts of the world, and especially of nearly all the physicians of Boston, Mass., and of Lyons, in France, are more than counterbalanced by the fact that chloroform is dangerous to life. A marked change of opinion, in favor of ether as against chloroform, has recently taken place in England. A large number of deaths from the inhalation of chloroform have occurred in the hands of the most skilful and experienced physicians. It is true that the number of deaths so produced bears a very small proportion to the total number of administrations, yet it should be remembered that only an extremely small number of deaths have ever been ascribed to the inhalation of sulphuric ether, and those perhaps incorrectly, and that the latter agent is equally efficient at the cost of a trifling inconvenience and a few seconds more time. Deaths from chloroform take place in three ways: 1, gradual asphyxia, for which the remedy is removal of the drug and fresh air; 2, sudden apnea or cessation of respiration, followed by asphyxia, for which the remedy is artificial respiration and the galvanic battery; 3, syncope from heart-shock, for which there is probably no remedy. Besides its use as a surgical anæsthetic, the inhalation of chloroform has been employed in midwifery, and to relieve intense pain, and to control convulsions, especially those produced by tetanus and strychnia. There is no record of death from its employment in obstetric practice in skilled hands, although there seems to be no good reason for its being safer in this department of practice than in others. Inhaled in the quantity of a few drops and largely diluted with atmospheric air, so as not to produce anæsthesia, it is used to relieve cough and irritability of the air passages. It may be administered by the stomach, combined with ether, sirup, mucilage, or glycerine, for the relief of nausea, seasickness, and nervous irritability. The writer has seen two ounces of chloroform, swallowed with suicidal intent, prove fatal in less than an hour. Applied externally, it is an irritant. Dr. Augustus Waller has shown that the admixture of chloroform greatly promotes the rapidity with which belladonna and probably other substances are absorbed by the skin. Chloroform is also used as a solvent in the preparation and purification of alkaloids and other substances for pharmaceutical and analytical purposes. (See ANÆSTHETICS.)

CHLORO-METHYL, or **Bichloride of Methylene**, a substance produced by exposing to sunshine, in a glass globe, chlorine and gaseous chloride of methyl. The products of the decomposition, which consist, in addition to the chloro-methyl, chiefly of chloroform, are collected in bottles, artificially cooled and connected with the generating globe. The chloride of methyl may be made for the purpose by heating together one part of wood spirit, two parts of common salt,

and three of sulphuric acid, and collecting the gas over water. The chloride of methyl possesses anæsthetic properties, but is less manageable than the bichloride, which is the subject of this article. The latter is a colorless liquid, of an odor analogous to that of chloroform, of specific gravity 1.344 and boiling point 88°. Its formula is $C_2H_2Cl_2$. It mixes readily with absolute ether, and the mixture volatilizes evenly and equally. When inhaled it produces, according to Dr. B. W. Richardson, insensibility without previous excitement, and the insensibility when produced continues longer without an additional administration than that caused by other anæsthetics. It may be made to destroy life, but after death muscular irritability remains longer than with some other anæsthetics, and consequently the chances of a restoration of the vital functions are greater. The bichloride of methylene has been somewhat employed as a surgical anæsthetic by Dr. Richardson, who first brought it into notice for this purpose, and by others. It seems to be more agreeable than ether, but unfortunately does not share with ether the superiority over chloroform of being less dangerous to life.

CHLOROPHYL (Gr. *χλωρός*, green, and *φύλλον*, leaf), the substance which gives the green color to leaves and herbage. It may be dissolved from the leaves by alcohol or ether, and is found to consist partly of wax, and partly of a peculiar substance allied to indigo.

CHLOROSIS (from Gr. *χλωρός*, green), a disease characterized by pallor, with a greenish tint of the face. The disease has been called the "green sickness," and is known in past medical literature by a variety of synonymes. It affects chiefly girls at or near the period of puberty, and is generally connected with disorders of menstruation. This function in some cases is either arrested or performed insufficiently, and in some cases there is a marked loss of blood. Modern researches have shown that a constant and essential condition in cases of this disease is the morbid blood-change called anæmia, or impoverishment of the blood; the change consisting in a diminution of the red globules. Many of the symptoms in cases of chlorosis are doubtless attributable to this change in the blood; and some writers consider that the disease is, in fact, simply anæmia occurring especially in young girls, and often when the customary causes of impoverishment of the blood are wanting. The morbid complexion, which is more or less marked in different cases, is due chiefly to anæmia. Other common symptoms are muscular debility, tendency to faintness or syncope, susceptibility to cold, impaired ability for mental effort, with depression and irritability of temper. With these symptoms are often associated defective appetite, with sometimes a morbid craving for innutritious substances, such as chalk and slate; disturbance of digestion, manifested by a variety of symptoms; palpitation of the heart; pain in the side, especially the left side, attributable to

intercostal neuralgia; neuralgic affections in other situations; consumption, leucorrhœa, and various other ailments. A constant sign, representing the blood-change, is the venous hum, called by French writers *bruit de diable* (the word *diable* relating to the toy known as the humming top). This sign is a continuous humming sound, sometimes musical, heard through the stethoscope applied to the neck, especially on the right side, the head being turned as far as possible in a direction opposite to the side on which the stethoscope is applied, and the patient being either sitting or standing. The sound is caused by the movement of the current of blood in the veins of the neck. An abnormal sound, known as a bellows or blowing murmur, is usually heard when the stethoscope is applied over the aorta and pulmonary artery, just above the heart, also over the carotid and other arteries of considerable size. These blood-murmurs are valuable to the physician as evidence of anæmia, and their disappearance serves to show that the anæmic condition is removed. The causation of chlorosis is evidently connected with the evolution of the sexual system, but it is not easy in the existing state of our knowledge to give a pathological explanation of the connection. So far as the anæmic condition is concerned, in some cases this is produced and kept up by immoderate menstruation and insufficient alimentation.—In the medical treatment of chlorosis, the preparations of iron are especially to be relied upon. These are sometimes rapidly effective, but often to secure their full efficiency they must be continued for a long period. Tonic remedies to promote appetite and digestion are useful. Using proper reserve with reference to the risk of abuse, wine may be advised with advantage, and Burgundy wine is generally considered most appropriate. Malt liquors are sometimes taken with benefit. Hygienic measures, however, constitute an essential part of the treatment. These measures consist of out-of-door life, change of scene, mental recreation, and as nutritious alimentation as practicable. The affection is not in itself serious, nor does it involve a tendency to any grave disease. Under judicious management the recovery of health may be confidently expected.—An essential element in chlorosis, as already stated, is anæmia, or impoverishment of the blood. The red globules, instead of being in the normal proportion of from 120 to 130 in 1,000 parts, may decrease to 70, 60, or even nearly to 20. The term anæmia is also employed to denote a deficiency of blood in any of the organs of the body; thus, cerebral anæmia means a deficiency of blood within the substance of the brain. In this sense of the term it is the opposite of hyperæmia, or congestion. Ischæmia is a term lately introduced to express a local anæmia. Anæmia is of frequent occurrence, exclusive of cases of chlorosis, and much more frequent in women than in men. The relative proportion of the

red globules to the other constituents of the blood in health is somewhat less in the former than in the latter; and besides there are several causes of anæmia peculiar to women, namely, child-bearing, lactation, and excessive menstruation. It is an effect of the loss of blood or hæmorrhage in any situation, the explanation being that the red globules which are lost are not quickly renewed, their reproduction requiring more or less time. A deficiency of alimentary supplies, inability of the stomach to retain food, and defective assimilation give rise to the anæmic condition; also profuse suppuration, or the formation of morbid products involving an undue expenditure of the blood constituents. Thus, anæmia is incident to such diseases as chronic pleurisy, albuminuria or Bright's disease, chronic dysentery, &c., which impoverish the blood. Again, certain diseases occasion anæmia by interfering with the production of red globules in modes not fully explicable with our present knowledge. Examples are the so-called malarial affections, lead poisoning, diphtheria, cirrhosis of the liver, &c. The effect of anæmia is to impair the functional ability of all the important organs of the body—in other words, to diminish vital power throughout the system. In the practice of medicine, it is very necessary to take cognizance of the anæmic condition as a pathological element which may either enter into, or be incidentally connected with, a great variety of diseases. The phenomena of anæmia are especially manifested in disorders of the nervous system. Many of the affections of the nervous system which are distinguished as functional, belonging among the affections called the *neuroses*, are in a great measure caused and kept up by the anæmic condition; and the treatment of these affections, to be successful, must proceed from an appreciation of this connection. With reference to the treatment in cases of anæmia, it is of course of primary importance to determine its causes, and if possible to remove them. This is not practicable when the anæmia is incidental to such diseases as consumption, cancer, &c.; but it can be done when the anæmic condition depends on lactation, insufficient alimentation, and certain affections, as for example those due to malaria, which are under the control of medical art. Under all circumstances anæmia offers certain indications for remedies and other measures of treatment which relate directly to the impoverished state of the blood. These have been already stated in connection with chlorosis. If the condition has been produced by causes which are either temporary or removable, the success of treatment strikingly exemplifies the improvement in medical practice derived from the recently acquired knowledge of this morbid condition.

CHMIELNICKI, Bogdan, chief of the revolted Cossacks, under the reigns of Ladislas IV. and John Casimir of Poland, born in 1593, died Aug. 25, 1657. He was the son of a Polish no-

bleman, who settled among the Cossacks of the Ukraine. This people, who had long defended the eastern boundaries of Poland against the Tartars and Russians, were at that time subjected to grievous oppression. Their religion was persecuted, their freedom circumscribed; the castle of Kudak, called the curb of the Cossacks, was built to restrain them. Thus exasperated, they seized Kudak and massacred the garrison, but were soon subdued. After their defeat, Bogdan was sent to the court of Ladislas, where he was favorably received and appointed secretary of the Zaporogian Cossacks. But envy, suspicion, and hatred soon drove him forth, and finally made him a scourge of Poland. The intrigues of Czaplicki, an official at Czehryn, deprived him of an inherited estate, and of his wife, who deserted him and her religion, and caused his son Timofey to be publicly whipped. Having in vain sought for redress at Warsaw, he entered into a conspiracy with the Cossacks against the Poles, and sought the alliance of the khan of the Tartars, who ordered 80,000 of his people to assist him. He now revolted, and commanded the massacre of all the Poles, Catholic priests, and Jews. The son of the hetman Potocki, who was sent against him, was deserted and fell in the battle at the Yellow Waters, and the hetman himself was made prisoner in that of Korsun (1648). Three other commanders were ignominiously defeated at Pilawce. Chmielnicki was master of the Ukraine, and carried terror, devastation, and death as far as Lemberg and Zamosc, but stopped there, awaiting the result of the election of a king, held at Warsaw. Under the new king, John Casimir, the war was continued with equal cruelty on both sides. Victories and defeats followed by turns, conditions of peace were offered and rejected, treaties concluded and violated, provinces desolated, fiendish atrocities committed; the serfs even of the Polish districts rose for freedom and rapine. Chmielnicki put himself under the protection of Turkey, of Russia (1654), and again under that of Poland (1656). A long war between Russia and Poland broke out after his death, which ended in 1667 with the cession of Kiev, Smolensk, and the Ukraine to the czar.

CHOATE, Rufus, an American lawyer, born at Essex, Mass., Oct. 1, 1799, died in Halifax, Nova Scotia, July 13, 1859. He graduated at Dartmouth college in 1819, was tutor there for a year, then studied law, and in 1824 commenced practice at Danvers, Mass., but soon afterward removed to Salem. In 1825 he was elected representative in the Massachusetts legislature, in 1827 state senator, and in 1832 a representative in congress. He declined a reëlection, and taking up his residence in Boston entered upon the practice of his profession, in which he soon rose to the highest rank, being recognized as one of the most acute lawyers and the ablest advocate of the Massachusetts bar. In 1841 he was elected United States senator to fill the unexpired term of Daniel

Webster. In the senate he made several eloquent speeches, but his true sphere was rather that of a lawyer than of a politician. At the close of his senatorial term, in 1846, he resumed his practice in Boston. In 1853 he was attorney general of the state, and was thenceforth to the close of his life the foremost lawyer in New England. He died while on his way to Europe for the benefit of his health. Mr. Choate was perhaps the most effective pleader of the day; and apart from his purely legal efforts, his reputation rests upon two or three speeches delivered in the senate of the United States, and some occasional addresses and orations. The principal of these are a eulogy upon President Harrison (1841), an address upon the anniversary of the landing of the pilgrim fathers (1843), a eulogy upon Daniel Webster (1853), an address at the dedication of the Peabody institution in Danvers (1854), an oration before the young men's democratic club of Boston (1858), two addresses before the law school at Cambridge, and two lectures before the mercantile library association of Boston. His "Works, with a Memoir," by Prof. S. G. Brown, including correspondence, have been published (2 vols., Boston, 1862).

CHOCIM. See KHOTIN.

CHOCO, formerly a province of New Granada, now a district of the state of Cauca, in the United States of Colombia, bordering on the Pacific and touching the gulf of Darien on the N. E.; pop. about 45,000, mostly negroes and mulattoes, with a few whites and Indians. It is traversed by the western branch of the Andes, and drained by the San Juan and Atrato rivers. The climate is warm, moist, and unhealthy. The soil is rich and productive, but agriculture is generally neglected, almost everything that is consumed, excepting plantains, fruit, and fish, being imported. Gold is abundant in the mountains and in the beds of the streams, and platinum is found on the W. side of the Cordillera; but mining and industry are at a low ebb. The principal towns are Quibdo and Novita.—There is a bay of the same name on the Pacific coast, between Points Guascama and Chirambira, lat. 2° 40' and 4° 18' N.; and another, forming the S. part of the gulf of Darien, which receives the Atrato.

CHOCOLATE (Aztec, *chocolatl*), an alimentary preparation, usually a beverage, introduced into Europe by the Spaniards in 1520, and by them kept for a long time a secret. It is prepared from the fruit of the *theobroma cacao*, a name given by Linnæus, who was so fond of it as to call it the food of the gods. (See CACAO.) The ancient Aztecs are said to have been very skilful in its fabrication, producing a froth which on cooling was solid enough to be eaten. Their favorite flavoring was vanilla, but they also used other spices. In the West Indies, the beans on being gathered are immediately dried and packed for market. They thus possess, however, a slightly acrid bitter taste, which in Carácas is removed

by a slight fermentation which is produced by covering them with stones or earth, after which they are dried in the sun. In manufacturing chocolate the beans are gently roasted in an iron cylinder similar to that used for roasting coffee. The development of a peculiar aroma indicates the completion of the process, when the beans are turned out, cooled, freed by sifting and fanning from their husks, and by trituration at a temperature of 130° F. in a mortar or a mill reduced to a paste, which is then mixed with from one half to equal parts of sugar and a small quantity of vanilla bean for flavoring, and, the proper temperature having been preserved, turned into moulds. Chocolate is easy of adulteration, and it is often diluted with farinaceous substances, as arrowroot, sago, or wheat flour, and with animal fats.

CHOCTAW. I. A S. W. county of Alabama, bordering on Mississippi; area, about 800 sq. m.; pop. in 1870, 12,676, of whom 6,872 were colored. The Tombigbee river, which flows along the E. boundary, is navigable by steamboats. It is well watered by affluents of the Tombigbee. The chief productions in 1870 were 227,715 bushels of Indian corn, 47,626 of sweet potatoes, and 6,439 bales of cotton. There were 1,313 horses, 941 mules and asses, 3,133 milch cows, 7,103 other cattle, 2,940 sheep, and 14,082 swine. Capital, Butler. II. A central county of Mississippi, traversed by the Big Black river; pop. in 1870, 16,988 of whom 4,462 were colored. The former area was 990 sq. m., but a portion was taken in 1870 to form Grenada county. Forests of oak, hickory, and other timber occupy much of the land; the remainder is fertile. The chief productions in 1870 were 7,844 bushels of wheat, 432,751 of Indian corn, 10,578 lbs. of wool, and 5,637 bales of cotton. There were 2,276 horses, 1,567 mules and asses, 4,173 milch cows, 7,584 other cattle, 7,618 sheep, and 25,892 swine. Capital, Greensborough.

CHOCTAWS, or *Chahtas*, an extensive nation of North American Indians, who, with the Alibamons, Timuquas, and kindred tribes, and the Muskogeas, occupied nearly all the territory on the gulf of Mexico from the Mississippi to the Atlantic. They claimed to have come out of a cave in a hill, which they regarded as sacred. The Chahtas, or Choctaws proper, comprising three divisions or fires, occupied a rectangular territory south of the Chickasaws and west of the Muskogeas, comprising what is now central and southern Mississippi and western Alabama. They cultivated the soil and subsisted chiefly by agriculture. They were raw-boned, active, and deceitful. From the practice of flattening the foreheads of their children with bags of sand, they obtained from the French the name of Flatheads. De Soto was the first to enter their territory, seizing the cacique of Coosa, and fighting a bloody battle with them at Mavilla in 1540. The next Spanish force, under Tristan de Luna, in 1560 aided them in a war with the Natchez. When the French set-

fled Louisiana the Chahtas became their allies, and missions and forts were established among them. At this time they comprised 40 villages and more than 2,500 warriors. They aided the French materially in the war against the Natchez, whom they signally defeated, and also against the Chickasaws. The English, however, began to seek their alliance, and won over a part of them, the chief Red Shoes becoming their fast friend. They acknowledged the sovereignty of the United States at the treaty of Hopewell in January, 1786, and were guaranteed peaceable possession of their lands. But as early as 1800 numbers emigrated beyond the Mississippi, and in 1803 it was estimated that 500 families had departed. The whole nation would have followed but for the opposition of the Spaniards and some of the western tribes. They did good service in the war with England and in the Creek war, and in 1820, by

A Choctaw.

the treaty of Doak's Stand, ceded to the United States a part of their territory for lands west of Arkansas. Georgia finally extended the state jurisdiction over the whole of the old Choctaw territory, and gave the Indians the rights of citizens. Preferring however to remove, they ceded the rest of their lands by the treaty of Dancing Rabbit creek in 1830, and with the Chickasaws, who had joined them, removed west of Arkansas, between the Arkansas and Canadian rivers on the north and the Red river on the south. They ceded in all 19,000,000 acres, and received 20,000,000, with \$2,225,000 in money and goods. The missionaries of the American board of commissioners for foreign missions had begun their labors among them in 1818, and were followed by the Presbyterians, Baptists, and Methodists. The Choctaws were making rapid progress in

agriculture and the mechanic arts. They are governed by a written constitution adopted in 1838, and amended a few years after so as to harmonize more with state governments. They elect their chief for four years, and have a national council of 40 members and a regular judiciary, with trial by jury. Under this government they advanced rapidly, increasing in numbers, wealth, intelligence, and civilization, and in 1861 had a population, including the Chickasaws, of 25,000, with 5,000 negro slaves. The superintendent and agents appointed by the United States took sides with the seceding states, and led the Choctaws to break with the United States government. Though their territory was not the scene of hostilities, the schools were closed, and the buildings, occupied by confederate troops, became a total loss, while the population was reduced to 17,000, of whom 12,500 were Choctaws. After the war, the government held that, by revolting and making treaties with the Confederate States, they had forfeited all their rights. New treaties were made in 1866, by which slavery was abolished, and part of their lands ceded for other tribes which the government wished to remove. A sort of territorial government was formed, with the superintendent as governor, and the powers of the council defined. The negroes were either to have lands set apart for them in severalty, or \$300,000 in the hands of government was to be taken for their use. Up to 1872 this point remained unadjusted, the Choctaws refusing to divide their lands among themselves in severalty, and being still more reluctant to give separate allotments to the negroes.—The Choctaw language lacks the verb "to be," and in many nouns, verbs, and adjectives, a plural form. It has many irregular forms, abounds in particles, both prefixes and suffixes, repeats the pronouns, and has many fragmentary pronouns, the article-pronouns involving great difficulty. A grammar by the late Rev. C. Byington (Philadelphia, 1870) gives a very clear view of the language; his dictionary has not yet appeared. The labors of the missionaries for more than half a century, giving them nearly the whole Bible, with spellers, definers, tracts, and hymn books, printed from 1826 to the present time, have made these works standard.

CHODOWIECKI, Daniel Nikolaus, a German painter and engraver, born in Dantzic, Oct. 16, 1726, died in Berlin, Feb. 7, 1801. He was at first engaged in trade in Dantzic and Berlin, but devoted his leisure to the practice of art, and in 1754 he set up as a miniature painter with considerable success. In 1756 he betook himself to etching, chiefly from his own designs, and acquired a reputation equal if not superior to that of any artist of his age in Europe. In 1764 he was appointed rector of the royal academy of arts at Berlin, in 1788 vice director, and in 1799 director. He was very industrious, and labored incessantly till within a few weeks of his death. His prints

numbered about 2,000, but they were generally small and executed for booksellers and newspapers. His subjects are chiefly illustrative of incidents in common life and history, and are remarkable for their expression. Of his oil paintings, the "Blind Man's Buff" and the "Cock Fight" are in the Berlin museum, and the "Resting Place" in the museum of Leipsic. Jacobi, a printseller of Berlin, published a complete catalogue of his prints in 1814. There is another in Heineken's "Dictionary," arranged according to the subjects.—His son WILHELM (1765–1805) was also a distinguished engraver.

CHODZKO, Alexander Boreyko, a Polish traveller, linguist, and poet, born at Krzywice, in Lithuania, July 11, 1804. He studied oriental languages at Wilna, went in 1829 to Persia, where he served as dragoman and consul, returned in 1841 to Europe, and has since resided mainly in France. As an author he is known by works in Polish, English, and French. His Polish poems, including translations from the Persian, appeared in Posen in 1833. His "Specimens of the Popular Poetry of Persia, as found in the Adventures and Improvisations of Kurrogroul, the Bandit Minstrel of Northern Persia" (London, 1842), are valuable as spirited translations, and for an appendix containing fragments of the original songs in the Turkoman, Perso-Turkish, and Zendo-Persian languages. Among his other works are: *Grammaire persane* (Paris, 1852); *Le dragoman turc* (1855); *Répertoire du théâtre persan* (1856); and *Chants populaires slaves* (1865).

CHODZKO, Jakób Leonard, a Polish scholar, born at Oborek, in the neighborhood of Wilna, Nov. 6, 1800. He studied at Molodeczno, where he enjoyed the friendship of Zan, and at Wilna, under the guidance of the historian Lelewel. Having travelled as secretary of Prince Oginski through nearly all Europe, he established himself in 1826 in Paris, where he published a memoir of the prince, with an introduction entitled *Observations sur la Pologne et les Polonais* (Paris, 1827), and commenced collecting materials for a history of his country from the death of Augustus III. Afterward he published *Histoire des légions polonaises en Italie* (2 vols., Paris, 1829), and several other works relating to Poland. During the revolution of July, 1830, Lafayette appointed him his aide-de-camp; and after the outbreak of Nov. 29 of the same year in Warsaw, he acted as agent of the revolutionary government in France. He was an active member of the French-Polish and American-Polish committees. His writings include *Tableau des révolutions de la Pologne* (1837); *La Pologne historique, littéraire, monumentale*, &c. (3 vols. 8vo, 1834–'47); *Histoire de Pologne* (4to, 1855; 14th ed., 8vo, 1864); *Histoire de Turquie* (4to, 1855); and *Contes des paysans et des pâtres slaves* (1864).

CHŒNIX (Gr. χœνιξ), a dry measure of capacity among the ancient Greeks. Its size is variously given, and it is probable that it differed

in the different states of Greece. Some accounts represent it as containing three *cotylæ*, or about 1·487 pint English; others make it equal to 1·982 pint; and still others give it as equal to 3·964 pints. The chœnix appears to have been the daily allowance for one man, differing probably for various kinds of grain.

CHŒRILUS. I. An Athenian tragic poet, contemporary with Thespis and Æschylus, and perhaps also with Sophocles. He first competed for the tragic prize in 523 B. C., and was still highly esteemed as an author in 483. He carried off the tragic prize 13 times, and is said to have composed 150 tragedies, besides other works, all now lost. **II.** A Greek epic poet of Samos, who flourished in the 5th century B. C. He was a friend of Herodotus. A few fragments only are preserved of his poems.

CHOL. See KHOL.

CHOIN. I. Marie Émilie Joly de, a French noble woman, born in Bourg, died in 1744. Introduced by the princess de Conti at the court of Louis XIV., his son, the dauphin, is said to have secretly married her, after which she was treated with the same regard which was paid to Mme. de Maintenon, the king eventually inviting her to reside near his court at Versailles, but she preferred to remain at Meudon. After the death of the dauphin she lived in great retirement, and was respected for her dignity and virtues. **II. Louis Albert Joly de**, a French prelate, born in Bourg, Jan. 22, 1702, died April 16, 1759. In 1730 he became bishop of Toulon, and acquired renown by the simplicity and purity of his life, by his charitable works, and by his *Instruction sur le rituel* (3 vols., Lyons, 1778; new ed. by Cardinal Gousset, 6 vols., Besançon, 1828), which is noted for the fulness of its information on ecclesiastical subjects.

CHOISEUL. I. Étienne François, duke de, a French statesman, born June 28, 1719, died in Paris, May 8, 1785. He was educated at a Jesuit college, and entered the army, being at first known as count de Stainville, and attained the rank of lieutenant general. Mme. de Pompadour procured for him the embassy to Rome, and afterward to Vienna, and finally in 1758 the department of foreign affairs. A little after he was created duke and peer; in 1761 he was placed at the head of the war department, transmitting his former office to his cousin the duke de Praslin, and also presided over the navy. In 1766 he resumed his functions as minister of foreign affairs. He signalized his administration by many useful reforms in the army and navy. To prepare against the attacks of England, Choiseul concluded the treaty known as the family compact, by which all branches of the Bourbons were united to resist foreign aggression. He also published in 1764 the famous edict for the suppression of the Jesuits in France. When Mme. de Pompadour died, he could easily have preserved his office by courting the favor of her successor, Mme. du Barry; but he treated her with such con-

tempt that he was dismissed and banished to his estate at Chanteloup. The regard in which he was held followed him to his place of exile, and his friends resorted thither to pay their respects to the fallen minister. He had endeavored, but in vain, to prevent the partition of Poland, and when the event took place Louis XV. said, "This would not have been if Choiseul had been minister." He died childless, and notwithstanding his income from his offices, and the large fortune brought him by his wife, the daughter of the wealthy financier Crozat, he was in debt to such an amount that all his estates were barely sufficient to satisfy his creditors. **II. Claude Antoine Gabriel**, duke de, a peer of France, nephew and protégé of the preceding, born in 1762, died in Paris, Dec. 2, 1838. As colonel of dragoons, in 1791, he was active in preparing the flight of Louis XVI. and the royal family. On the failure of this attempt he was arrested, but recovered his liberty by the amnesty granted on the acceptance of the constitution by the king. Appointed first gentleman usher to the queen, he attended her until her imprisonment, and left France only when a price was set upon his head. Raising a regiment of hussars, he joined the royalist army, was taken prisoner, escaped, embarked for India, was wrecked on the coast of France, arrested and sentenced to death by the directory, but saved by the revolution of the 18th Brumaire. He kept aloof from public life during the reign of Napoleon, but on the restoration he was appointed a member of the new chamber of peers. He refused to sentence Ney to death, pleaded for Gen. Merlin, implicated in a conspiracy, resigned on the advent of the Villèle ministry, in 1820, the rank of major general of the national guard, and when the revolution of 1830 broke out, he was without his knowledge nominated, with Gérard and Lafayette, a member of the provisional government. He was afterward appointed aide-de-camp to Louis Philippe.

CHOISEUL-GOUFFIER, Marie Gabriel Florent Auguste, count de, a French classical scholar, born in Paris, Sept. 27, 1752, died June 20, 1817. He studied under the direction of Barthélemy, travelled several years in Greece, and in 1782 published the first volume of his *Voyage pittoresque en Grèce*. He was then made ambassador at Constantinople. On the outbreak of the revolution he adhered to the king, and was proscribed by the revolutionary government. He retired to Russia, where he was intrusted with the direction of the academy of fine arts and the imperial libraries. In 1802 he returned to France. The second part of his great work was published in 1809; the last part did not appear till after his death, in 1824.

CHOISY, François Timoléon de, a French writer, born in Paris in 1644, died Oct. 2, 1724. His delicate appearance induced his mother to dress him in feminine attire; he continued to wear it for many years, and was in the early part of his life notorious for his dissolute habits. In

1676 he accompanied the cardinal de Bouillon to Rome to attend the election of Pope Innocent XI. In 1685 he went on a mission to the king of Siam, of which he has given an interesting account. On his return to France he devoted his whole time to literary pursuits, was elected to the academy in 1687, wrote the history of several French kings, and attempted to present the annals of the church in a more accessible form than the learned Fleury. His *Mémoires pour servir à l'histoire de Louis XIV.*, which have been printed in Michaud's *Collection de mémoires*, and his *Journal du voyage de Siam fait en 1685 et 1686*, are written in a lively and agreeable style.

CHOKO DAMP, the name given by miners to the irrespirable gas (carbonic acid) which fills the mine after an explosion of fire damp. This gas is also found in badly ventilated parts of mines, its presence being detected by the difficulty of making candles burn, and the violent headaches it brings upon those who remain for any time where it is abundant. When carbonic oxide is present, the gas is exceedingly dangerous to breathe for an instant; but one may sometimes stay with safety for a minute or two in an atmosphere of choke damp in which a candle cannot be lighted.

CHOLERA, a term used to designate a variety of diseases characterized by profuse discharges from the stomach and bowels upward, but more especially downward, and in their extreme stages by cramps, absence of the pulse, coldness and blueness of the skin, and suppression of urine. The name has generally but erroneously been derived from Gr. *χολή* and *ρῆα*, signifying a flow of bile; but it properly and more appropriately comes from *χολέρα*, a rain-gutter, as marking the fluidity, rapidity, and copiousness with which the discharges take place. The principal varieties are: 1. Cholera morbus, or that induced by the use of indigestible food, unripe fruits, spoiled meats, mouldy or corrupt provisions, blighted grain, cucumbers, melons, fat pork, stale crabs, lobsters, shell fish, incompletely fermented or sour liquors, bad drinking water, &c. The indications are to empty the stomach and bowels of the offending substances, and then to give an anodyne. 2. Catarrhal or serous cholera, produced by sudden check of perspiration, exposure to cold while heated, &c. The indication is to reproduce heat of the skin by warm clothing, warm drinks, &c. 3. Bilious or common cholera, produced in hot weather and by gross and luxurious feeding, &c. The indications are to evacuate the excessive and unhealthy bile, and then check its further secretion. 4. Anabillous cholera, in which the biliary secretion is much diminished or entirely suspended, or else is of a very light color, dirty white, almost colorless, or milky, and when abundant resembling the rice water evacuation of epidemic cholera. The indication is to restore the healthy secretion of bile. 5. Cholera infantum, a disease of warm sea-

sons, commencing with the first heats of summer, affecting almost exclusively infants and children in large towns and cities, prevailing in the parts most densely populated, and being most virulent in crowded courts and alleys, where the ventilation is very imperfect and the inhabitants most unclean. In fact it arises from a combination of hot weather and the impure air of cities, aided largely by bad food and poor milk. It somewhat approaches septic cholera in its nature. 6. Septic cholera, arising from the inhalation of air charged with organic impurities springing from decomposing vegetable and animal matter, sewer gases, and night soil. 7. True Asiatic cholera, a virulent form of septic cholera, always originating in Hindostan, and which, like the contagious forms of influenza, dysentery, or erysipelas, has become portable, communicable, and capable of reproducing itself in every body in which it gets lodgment. Hippocrates, 400 B. C., makes remarks about cholera which scarcely allow us to doubt of the conveyance of the Asiatic disease to Greece in that early period. Arctæus of Cappadocia, A. D. 50, gives a correct description of it, even describing the spasms, coldness of the body, loss of voice, and suppression of urine. Galen in A. D. 131, and Cælius Aurelianus in 151, did the same; also Orabasius of Pergamus (230); while Alexander of Tralles (525) speaks of the watery evacuations, suppression of pulse and urine, followed in some cases by secondary typhoid fever, or death in a few hours.—When the French and English struggled for the Coromandel coast of India, repeated epidemics were noticed near Madras and Pondicherry, in connection with the great Hindoo pilgrimages. The year 1756 marks the recognition of periodically returning 12-yearly epidemics, connected with the great 12-yearly Hindoo festivals at the great temples. The great 12-yearly epidemics of 1756, 1768, and 1781 have been well described by Paisley, Girdlestone, Curtis, Sonnerat, Fra Bartolomeo, Papin, Davis, and others. On March 22, 1781, 5,000 English troops under Col. Pearse, marching near Ganjam, not far from the great temple of Juggernaut, and very shortly after the huge 12-yearly festival had taken place, were attacked by the disease very suddenly and with inconceivable fury, after camping on foul pilgrim grounds and drinking polluted water. Men previously healthy dropped down by dozens, and those less severely affected were generally past recovery in 24 hours. Besides those who had died there were 500 on the sick list on the first day, and in two days more nearly 3,000 were affected. This epidemic was carried by returning pilgrims up to Calcutta and down to Madras. Three times 12 or 36 years subsequently the great historical epidemic of 1817 occurred; this proceeded up the Ganges as far as Allahabad, when it was deflected southward to the province of Bundelcund, in which the marquis of Hastings was carrying on war

against the Mahrattas with 90,000 men. Of the natives 10,000 had already died in Allahabad, and many others had joined the army as camp followers, among whom the disease crept about in its usual insidious manner for several days, until a sufficient number of foci of the disease had been developed for it to burst forth with irresistible fury in every direction. The natives deserted in great numbers, and the highways and fields for many miles around were strewn with the bodies of those who had fled with the disease upon them. The encampments and lines of march of the army presented most deplorable spectacles; hundreds of soldiers dropped down in every day's advance, and on every night's halt; so that the whole presented the appearance of successive battle fields and the track of an army retreating under every circumstance of defeat and discomfiture. In two weeks 9,000 men succumbed to the pestilence. A subsidiary force coming up from the south under Col. Adams to cooperate with the marquis of Hastings afforded the second striking instance of a large body of men in high health coming into the pestilential region and falling at once into a wretched state of sickness; 70 cases and 20 deaths occurred on the first day, and many were attacked while loitering for water at contaminated springs and rivulets. Other reinforcements were advancing from Bombay in the southwest, and the course of the disease had long been so regular along the line of much travelled roads and the marches of troops that the Bombay authorities prepared for it when it was many hundreds of miles off. Step by step the disease could be traced marching from town to town and creeping from village to village, by the arrival of persons affected with the disease from places where it was known to prevail. From Bombay it was carried up the Persian gulf to Bushire, the only port of southern Persia, from which it was transported by travellers to Shiraz; was excluded from Ispahan by a rigid quarantine, and deflected east to Yezd; from there north to Teheran, and from thence to Reshd, the principal Persian port on the Caspian sea; and from there both by land and water up to Astrakhan, at the mouth of the Volga, where the disease died out. From Bombay it was also carried up to Bassorah at the head of the Persian gulf, where 18,000 persons died in 18 days; and from there along the rivers Euphrates and Tigris to Bagdad, Damascus, Aleppo, and the Mediterranean coast, where it also faded away in 1821. Every successive epidemic of cholera has always been carried up the Persian gulf from Bombay, Surat, Kurrachee, and other ports on the western coast of India, and thus reached the Mediterranean, Black, and Caspian seas, and neighboring countries, by the so-called Persian gulf route. In the Bombay presidency there are 94 shrines to which large pilgrimages are made, and from which the disease is brought to the seacoast. In India the epidemic of 1817

spread in every direction with the march of armies, pilgrims, merchants, and travellers, often in the face of contrary winds and monsoons, although the speed of its progress was accelerated by favoring winds which forced along vessels containing the disease. It was conveyed south in ships to Ceylon, and southwest to Mauritius, and over to Zanzibar on the east coast of Africa, and from there up to Muscat at the foot of the Persian gulf, in slave ships, and down again southeast to Bombay. It was also carried east to Burmah, Siam, Malacca, Sumatra, Java, Borneo, the Philippine islands, and northeast to Canton in China by ships. This epidemic and that of 1781 were distinctly Juggernaut-pilgrim choleras, and for years after we have a repetition of the old story: "Cholera in Calcutta; the pilgrims at Juggernaut suffering severely."—In 1826 the first indications of another pestilence appeared in the north of India; epidemic cholera broke out at Hurdwar, the great place of pilgrimage at the source of the Ganges, where it first issues from the foot of the Himalaya mountains. A few hundred thousand pilgrims go to Hurdwar every year; more every third year; still more every sixth and ninth years, and fully 3,000,000 assemble every 12th year, and a vaster number every 60th year. From Hurdwar cholera was carried back by the huge caravans which came down to the festival from central Asia, Persia, and Afghanistan, to Cabool. Then the disease advanced over the great northwest central Asiatic caravan route to Balkh, Bokhara, and Khiva, and to Orenburg in Russia; also from Cabool by the north Persian route due west to Herat, Meshed, Teheran, and Reshd, at the foot of the Caspian sea; and from there up to Astrakhan in Russia, both by sea and land. Cholera reached Orenburg on Aug. 26, 1829, and Astrakhan in September. From Orenburg it proceeded due west to Nijni Novgorod and Moscow; and from Astrakhan it advanced step by step up the Volga toward the same places, until the stream which had flowed through central Asia to western Russia and Orenburg formed a junction with that which entered southern Russia from the northern provinces of Persia. From Moscow the disease was distributed all over northern and western Russia, especially to Riga, on the Baltic, from which 60 or 70 English coal vessels fled in haste, carrying the disease to Sunderland and Newcastle in England. At this time the great Polish revolution of 1830-'31 was going on, and Russian troops carried the disease to Warsaw, whence it was conveyed due west to Posen and Berlin, and from there to Hamburg and over to London. After the pestilence had prevailed in England, Ireland, and Scotland, it was carried by 10 or 12 Irish emigrant ships to Quebec in the spring of 1832, and from there up the St. Lawrence and across the lakes to Detroit, where it met the United States troops going to the Black Hawk war. In a short time the whole force sent by way of

the lakes was rendered incapable of taking the field; some were left behind, but the greater part reached Chicago in a most deplorable condition; one company which had been mustered and inspected 14 days before without a man on the sick list, had dropped 47 men out of 78 in that short time; and one regiment lost over 200 men in a week. It was generally believed that the infection was contracted by the soldiers on the steamboats which had been previously engaged in transporting crowds of emigrants westward from Montreal and Quebec; and the army surgeons agreed in asserting that previous to the arrival of these steamboats not a case had been observed in Chicago. It was distributed to all the national posts and forts in the extreme west, especially to Fort Dearborn at Chicago, Fort Crawford near Prairie du Chien, and Fort Armstrong at Rock Island. From there the pestilence was carried down the Mississippi to New Orleans by October, 1832; and Surgeon General Lawson says, "One fact is certain: no case of cholera occurred in New Orleans until after the arrival of steamboats with cases of cholera on board, and after a number of their passengers had died of it; 6,000 died out of a population of 55,000."—The next great 12-yearly epidemic commenced in lower Bengal in 1841, advanced over India and toward the N. W. provinces; was supplemented by a Hurdwar epidemic in 1843, and was found in Afghanistan in 1844, in Persia and Meshed in 1845, advancing west in 1846 to Teheran, and up between the Black and Caspian seas toward southern Russia, reaching Astrakhan July 30, 1847. But especially it was deflected west to Trebizond and Poti, on the southern and eastern coasts of the Black sea, and from there carried over to Constantinople and Odessa, and up the Danube to Germany, whence it was carried to Holland and England. Toward the close of the year 1848 numbers of German emigrants arrived at Havre, and some of them were carried to New Orleans on the ship Swanton, with 13 deaths from cholera before arrival, and from which six cases were sent on shore. Dr. Fenner says, after the disease had once commenced in New Orleans, almost every vessel and steamer leaving that city had 20 or 30 cases on board; and thus persons having cholera and dying with it were carried to all the landing towns and cities up the Mississippi and Ohio rivers as high up as Cincinnati. From St. Louis it was carried over the emigrant route to San Francisco; more than 1,000 emigrants died on the road, and many Indians who loitered along from curiosity and for the purpose of begging paid a terrible penalty. In the mean while the Austrian, Hungarian, and Russian armies contending in Hungary in the spring and summer of 1849 had become the principal centre and focus of the disease, whence it spread with terrible virulence into Poland and Germany.—The next and last great 12-yearly epidemic commenced in India in April, 1865. By means of railroads and steamboats,

it reached Mecca on the Red sea by May 2; in Alexandria, June 2, cases were frequent; from there it was carried by steamships to Smyrna, Constantinople, and up the Black sea; to Malta, Ancona in Italy; to Marseilles, Gibraltar, Barcelona, Algiers, Tunis; and to Southampton in England by the steamship Poona by July 10, with 120 cases of cholera by July 24. But more especially the disease was conveyed up through France from Marseilles to Paris and Havre; and emigrant ships quickly transported the disease over to America, principally to New York. From New York it was distributed in 1866 in every direction over the United States, by railroads and steamboats, even as far west as the Smoky Fork river in Kansas; to Forts Riley and Harker, and to the new town of Ellsworth, then only six weeks old, because soldiers, railroad laborers, and others from infected districts brought the disease to the new line of railroad then building.—Thus we have sketched the great route lines of cholera and the great 12-yearly epidemics. The next one, if our theory is correct, will be a Juggernaut one in 1877, supplemented by a Hurdwar cholera in 1879; although the constant intercourse of Russia with central Asia, and her expeditions in Turkistan, may be the means of introducing a lesser epidemic into Europe, as they are doing at the present time. But in 1877 and 1879 we may expect an outbreak of the disease, such as there was in 1781 and 1783, 1817 and 1819, 1829 and 1831, 1841 and 1843, 1853 and 1855, and 1865 and 1867. As Hindostan, in which cholera always originates, lies to the east and south of Europe and North America, the prevailing direction in which the disease always advances is to the west and north; but as it always proceeds along the lines of the greatest and most rapid travel, it often doubles back upon itself. Thus in 1832 it was carried south from England to Holland and France, down to Marseilles; east to Italy, up toward Vienna, and south to Malta toward Alexandria; also down to Spain and back through the Mediterranean. In 1841 and 1842 it was carried by English troops from India to China, back toward Burmah, central Asia, and Bokhara, south into Hindostan as far as the mouth of the Indus, and low down the Ganges. In the Crimean war it was carried east from France and Algiers to Turkey. In 1865 it was taken from Alexandria to Constantinople, from there across the Black sea to Trebizond, Circassia, and Armenia, toward Persia. In our next contests with the disease our whole safety lies in quarantine and thorough disinfection. Bokhara, the holy city of central Asia; Meshed, the holy city of Persia; Mecca, the holy city of Arabia; and the huge pilgrimages to and from them, are the first great outposts of danger. Next come the great distributing ports of Alexandria, Trebizond, Poti, Astrakhan, and Orenburg; next Constantinople, Odessa, and the Baltic ports; next Marseilles, Havre, and Liverpool; finally

our Atlantic ports. The disease can be stopped at any one of these outlets and inlets. It has never yet been carried across the Pacific; but with the vast increase of our Pacific commerce with China and Japan, it must sooner or later reach California from that direction.—As all the most virulent epidemics, from Hurdwar to London, have been connected with the contamination of drinking water by cholera evacuations, there is but little danger of a very extensive outbreak of the disease in any city where the drinking water is originally pure and is conveyed in close and clean pipes. Water sources must be zealously guarded; and it should be regarded as a penal offence, always to be followed by prompt and severe punishment, to foul the tributaries of a stream furnishing drinking water to any community. Cholera pollution of wells, springs, fountains, pumps, and small streams is only too common in all parts of the world, and is the most productive source of severe local outbreaks of the disease, and may always be suspected in every instance in which many cases occur simultaneously in one house, family, or neighborhood. There is even reason to believe that pure drinking water may become contaminated if left standing long in cholera wards, in open vessels; at least, a substance as virulent as croton oil has been condensed from the atmosphere of close and crowded cholera rooms. The ingestion of this water is vastly more fatal than the use of bad fruits or poor liquors; but its dangers may generally be prevented by simple boiling, or filtering through charcoal, or by adding a few grains of permanganate of potash. With these precautions cholera patients may be attended with great safety, provided the nurses be kept scrupulously clean, and no cups, plates, or drinking vessels be touched with soiled hands. Dust inhaled from cholera-soiled clothes, carpets, or floors is the next most dangerous substance; but the effect of this is confined to single rooms, houses, families, and confined spaces, and can never rise to the dignity of the cause of a great and extended epidemic. As the poison of the disease always proceeds from the cholera evacuations, these should be disinfected instantly and thoroughly; and common salt is perhaps as good a disinfectant as any. Strong solutions of salt, or weaker ones of sulphate of iron (copperas) or sulphate of zinc (white vitriol), 1 part to 10 of water, should be kept in the bed pans or vessels; soiled bed and body clothes should be put, before removal from the sick room, into a disinfecting solution of salt, chloride of soda, weak carbolic acid, permanganate of potash, or chloralum, and then subjected to careful washing out of doors. The floor of the sick room should always be bare of carpets, and may be sprinkled or washed with a strong solution of salt or chloralum, or the chloride of aluminum, all of which possess several advantages. They are not poisonous, are inodorous, and are very cheap. They prevent decomposition and re-

move the fetor of most animal discharges, either natural or the products of disease. They deodorize sewage, and may be used for the disinfection of rooms, and as a cleansing material for floors or furniture (2½ ounces to a gallon of water). But, not being volatile, they must be aided by aerial and diffusible disinfectants, the best of which are chlorine, iodine, and carbolic acid. The unpleasant odor of chloride of lime or soda may be overcome by the addition of a small quantity of nitro-benzole. Iodine placed in saucers in different parts of the sick room evaporates spontaneously; and if its odor can be detected, it is in sufficient quantity to disinfect the air. Or ½ lb. of carbolic acid may be mixed with 10 lbs. of wet sand, placed in shallow vessels in various parts of the room, and renewed when its odor has disappeared. It will be seen that the attempt to obtain a disinfectant of universal application, and capable of fulfilling every indication, will always be attended with disappointment. Some, like the chloride of soda and the sulphates of iron and zinc, prevent fermentation and putrefaction; others, like iodine, chlorine, and carbolic acid, resolve the products of decay and decomposition into harmless substances.—Although the first stage of cholera cannot be distinguished from a profuse watery diarrhoea, the treatment is very simple. In the first place, it should be fully believed that nine tenths of all cases of diarrhoea occurring in the summer season, even in cholera times, are not Asiatic cholera, and never will be. Even if the case be one of cholera, absolute repose in bed, between thin blankets, will cure at least one half of all cases without any medicine; then one or two grains of sulphate of iron, with or without a quarter or half a grain of opium, every two or four hours, will cure a great many more. In the severest and most neglected cases no treatment is of any avail; but from 5 to 20 per cent. of these will recover if not too much interfered with. The preventive measures are equally simple. As drinking cholera water is almost the only cause, a rather free use of salt and vinegar, which are the great domestic disinfectants, may be all that is essential. It is certainly unnecessary to abstain from ripe and good fruits and vegetables, while all sweet, fresh meats and farinaceous substances are beneficial. Even of those persons who swallow water into which cholera dejecta have found their way, all with healthy stomachs, containing healthy acid gastric juice, and food in the process of normal digestion, will escape. In some instances 15 out of 20 have escaped. But if cholera water be swallowed on an empty stomach some hours after taking food, then the cholera poison will set up its distinctive changes in the epithelium of the stomach, which speedily extend to that of the intestines, so that a robust, healthy, and otherwise prudent person may quickly succumb to the disease. Or, if more of such water be swallowed than the stomach will easily con-

tain, some of it will at once pass to the small intestines, and their contents being alkaline, the specific action of cholera matter will at once take place. Hence persons with weak digestion, and those suffering from depression of the nervous force, whether following excessive fatigue or a debauch, are especially apt to be attacked. Therefore the poor of large towns, who are ill fed and suffer from want of a healthy acid secretion from the gastric walls, are especially liable to the disease. Hard drinkers increase their risk by drinking large quantities of water after a debauch, to quench their unnatural thirst. But even all these will escape if they be fortunate enough not to drink foul cholera water.—The pathology of the disease is equally simple. The cholera poison first produces a paralysis of the vaso-motor nerves and capillaries of the stomach and bowels, allowing the watery particles of the blood to exude as if from a relaxed and sweating skin. Next, the epithelium of the gastro-intestinal mucous membrane is shed in large quantities, leaving the latter bare and almost raw, red, and filled with blood. In this stage strong stimulants and irritants are very injurious, while a few teaspoonfuls of arrowroot with a little brandy, given very frequently, will prove quite beneficial; and sweet oil and lime water is far better than castor oil, or other so-called eliminatives. As the disease advances the blood is drained of much of its serum or water, becomes thick, and stagnates in various places. It is no longer properly oxygenated, and becomes dark, marking the third stage of the disease, followed by exhaustion and perfect collapse; from which a small number may slowly rally, if carefully supplied with drink and weak stimulants in small quantities, frequently repeated. Of these, some will pass into a typhoid state, through retention of effete materials in the blood, especially of urea, from complete inaction of the kidneys. Then diuretics, more particularly nitre, cantharides, digitalis, or nux vomica, will save a small proportion. The great point in the whole course of the disease is not to be too hurried or agitated, nor too anxious to do too much and too quickly. Absolute rest and warmth, the careful use of food and weak stimulants, aided by small quantities of astringents and opiates, especially vinegar of opium, with an absence of all unmanly haste and fear, will save a large number who would fruitlessly rely upon vaunted specifics. Dr. Macpherson, who had seen and treated thousands of cases, when attacked himself at night, remained quietly in bed, took nothing but a little arrowroot and brandy with a few drops of laudanum, and occasional sips of carbonic acid water. In the morning he directed that an old and experienced medical friend should not be sent for until after he had finished his breakfast, and the usual time for going on his rounds had arrived. With these simple means, and the careful handling of an old and tried hospi-

tal steward, he was saved when on the borders of a profound collapse, and slowly and steadily brought back to life. All three of these wise and patient men were convinced that the more there was of haste, the more profusely food, stimulants, and drugs were plied, the more certainly fatal would be the result; and that the more steadily and quickly their few and simple means were used, the greater would be the chances of recovery. When he was cold and almost pulseless, and so exhausted as scarcely to be able to raise a finger or move his head, his courage did not fail him; and his skilled and wise attendants did not kill him with mistaken zeal and kindness.

CHOLESTERINE (Gr. *χολή*, bile, and *στερεός*, firm, solid), or **Biliary Fat**, a non-nitrogenized organic substance, found in the bile and in other fluids or situations in the human body, or that of animals in which the biliary secretion is prominent, this substance when separately obtained having the appearance of spermaceti, and differing from ordinary fats only in the fact that it refuses to form a soap with caustic alkalies, even under the action of prolonged heat. Cholesterol is neutral, inodorous, insoluble in water, soluble in ether and hot alcohol. Its composition is usually represented by the formula $C_{26}H_{44}O$. It is combustible and burns with a bright flame. It crystallizes in very thin, colorless, transparent, rhomboidal plates, frequently marked by a cleavage at one corner in a line parallel with the corresponding side, and often forming in layers, the borders of the subjacent plates showing very distinctly through those above. Cholesterol was discovered in 1782, by Poulletier de la Salle, in biliary calculi; its presence in the blood was shown in 1830 by Denis. In a condition of health, cholesterol exists in the bile, blood, liver, brain and nerves, and the crystalline lens. It is also found in very large quantity in the meconium, in the fæces of animals hibernating, and by some authorities it is said also in the fæces generally in health. It occurs frequently as a morbid deposit or product. Biliary calculi consist wholly of cholesterol, coloring matter, and mucus. The tablets of cholesterol are found in or obtained from cancerous growths, encysted tumors, and atheromatous deposits in the coats of the arteries, and sometimes as forming distinct deposits or tumors in the substance of the brain. Cholesterol is obtained also from the fluid of hydrocele, of ovarian cysts, of tubercle in the crude state, and from pus. Its quantity in the normal fluids is small, forming, according to Berzelius, 1 part in 1,000 of the bile in man, and according to Prof. Austin Flint, jr., of New York, only .618 in 1,000. The analyses of the latter give as the proportion in 1,000 parts, for the venous blood of the male, .445 to .751; for the meconium, 6.245; for the human brain (in two instances in which death was sudden), 7.729 to 11.456. The bile and some other fluids can hold the cholesterol in

solution, though by aid of what other constituent is not known; while it may perhaps exist, in organic union with other components, in the nervous substance and the crystalline lens. While the chemical relations of cholesterol had been fully studied, its physiological relations long remained in doubt, or the subject at the most of conjecture. According to the researches of Prof. Flint, cholesterol is constantly forming in the system, being always present in the nervous matter and the blood, but by far the most abundant in the former; it is a necessary product of the waste of the nervous matter, and being removed thence in the circulation constitutes one of the most important of the materials to be excreted from the body. It is separated from the blood by the liver, appears constantly in the bile, and in this is poured into the alimentary canal. As in the case of urea, the most important excreted matter of the kidneys, so with cholesterol, if its separation and removal through the liver ceases, or is not in due amount, this product accumulates in the system, producing its form also of poisoning or deterioration of the blood, and leading to a corresponding class of diseases. Thus the bile has two distinct functions answering to the presence of two entirely distinct components in it. One of these embraces the glyco-cholate and tauro-cholate of soda, which do not preëxist in the blood, and so do not accumulate in it when the liver is torpid or its action arrested; these are produced in the liver, serve a useful purpose in completing the process of digestion, are not discharged in the fæces, and constitute a secretion only. The other function of the liver is the depuration of the blood by freeing it of excess of cholesterol; and to this end probably it is that secretion of bile continues in the intervals of digestion, though more abundant during the digestive acts. The ordinary fæces, according to Prof. Flint, do not contain cholesterol, but contain stercorine; the substance thus named by the author being invariably found by him in the normal fæces, and regarded by him as identical with that previously found in minute quantity (.02 to .025 part in 1,000) in blood, and named seroline. The transformation of cholesterol to stercorine occurs during the digestive process; and that it does not take place before digestion commences, nor when it is for the time arrested, accounts for the presence of the former only in the meconium and the excrement of animals hibernating. Stercorine is therefore the form in which cholesterol is discharged from the body. The facts explain the distinction of the two types of jaundice. In the mild type the bile is formed, but its discharge being obstructed, its coloring matter chiefly is reabsorbed, and the disease is attended with yellowness of the skin, but is comparatively harmless; in the other, the grave symptoms and almost invariably fatal character are due to cessation of the action of the liver, with retention of choleste-

rine in the system. There is also a condition of the blood, which may or may not be attended with jaundice, due to a gradual and undue accumulation of cholesterine in that fluid, and to which Prof. Flint applies the name "cholesteræmia." This can only occur when, through some organic or structural change in the liver, and not merely of a small part, but of so much of it that the remaining healthy portion, if any, is insufficient for the depuration of the blood, the organ is in consequence incapable of performing duly its excretory office.

CHOLET, or **Chollet**, a town of France, department of Maine-et-Loire, on the Maine, 30 m. S. S. W. of Angers; pop. in 1866, 13,360. It is largely engaged in manufactures, having establishments for the spinning of cotton and woollen goods, known as *toiles de Cholet*, or *cholettes*, paper mills, bleacheries, tanneries, and dye houses. It suffered greatly from civil war during the revolution, its manufactures being destroyed, and the workmen put to death or dispersed. Since then it has been entirely rebuilt. A number of battles were fought here in 1792-'4 between the republicans and the Vendéans, in most of which the latter were defeated.

CHOLULA, a decayed town of Mexico, situated on the tableland of Anahuac, 6,912 ft. above the sea, in the state and 5 m. W. N. W. of the city of Puebla; pop. 10,000, wholly Indians. It was formerly the capital of an independent state of the same name, but is now little more than a village rapidly sinking into insignificance.

It has still some manufactures of coarse cotton goods, and is surrounded by well tilled gardens and plantations of corn and maguey. In its neighborhood stands the largest of the *teocallis* or pyramids of Mexico, consisting of an artificial, or as some travellers have supposed a natural hill, cased with layers of adobe, stone, and plaster, and forming a truncated pyramid of four equal sides, facing the cardinal points and divided into the same number of terraces. According to Humboldt's measurement, it is about 160 ft. in perpendicular height, 1,400 ft. square at the base, and covers an area of 45 acres. Latrobe states its elevation to be 177 ft. and the length of its base 1,425 ft. It is accessible on all sides, though time has destroyed the regularity of its outline, and covered its sides with trees and shrubs to the very summit. The platform on its top is more than an acre in extent, and is surrounded by a parapet. In its centre stands a chapel to the Vir-

gin, erected by the Spaniards, where masses are celebrated. A part of this pyramid has been laid open by the construction of a road across it, when a cavity was disclosed containing a number of vases, idols in basalt, and two skeletons. It was built in honor of the deity Quetzalcoatl, but its precise age is unknown. The Aztecs found it here when they settled in Anahuac. Close by are two smaller pyramids.—When the ancient empire of Mexico was in its glory, Cholula was the emporium of the plain, the seat of skilful manufactures, and a holy city where each race had its temples and sacrifices, and whither pilgrims resorted from the most distant quarters. Its streets were gay with the pomp of frequent festivals and processions, while on the summit of the great pyramid rose perpetual flames from the temple of Quetzalcoatl. This temple, a magnificent structure, and an object of profound national reverence, contained an image of the

Teocalli of Cholula.

god, wearing about his neck a golden collar, in his ears pendants of turquoise, and on his head a mitre with plumes. He bore a shield covered with emblems, and held in one hand a jewelled sceptre. It is related that at this and the numerous other shrines throughout the city 6,000 human beings were sacrificed every year. Cortes, who stopped at Cholula on his march to Mexico, described it as a beautiful and well fortified town, containing about 20,000 houses, besides which the suburbs were computed to embrace about as many more. He called it Churultecal. He was received by the inhabitants with apparent kindness, but learning that they were plotting against him he fell upon them unexpectedly, and gave the city up for several hours to massacre and pillage. In his letter to Charles V. he rates the loss of life at 3,000; but most accounts say 6,000.

CHOMEL, **Auguste François**, a French physician, born April 13, 1788, died in Paris, April 10,

1858. Under the instruction of Boyer, Corvisart, and Pinel, he made rapid progress in his studies, and at an early age was attached to the medical service of the hospitals in Paris. In 1813 he published an *Essai sur les rhumatismes*; in 1817, *Éléments de pathologie générale*; in 1821, *Traité des fièvres et des maladies pestilentielles*, which was attacked by Broussais, but which has outlived Broussais's theory, and made a reputation for the author. In 1827 Chomel was appointed professor of medicine at the faculty of Paris, as successor to the celebrated Laennec, whose views he held and taught in the same chair. His practice became more lucrative than that of any other physician in France. Genest, Requin, and Sestier published their notes of his clinical lectures on typhoid fevers, rheumatism, and pneumonia (3 vols. 8vo, 1836), which are still deemed standard works in France.

CHONTALES, a district of Nicaragua, N. E. of Lakes Nicaragua and Managua, separated from Honduras by the district of Segovia. The chain of the Cordilleras called the Alto Grande mountains traverses the district in a N. W. and S. E. direction, making up the greater part of it. The mining region, which gives the principal importance to this portion of Nicaragua, lies along the slopes of the mountains, and in this are several towns, mostly occupied by the native Indians. One of the most important of these is Libertad, 35 m. N. E. of Lake Nicaragua. The gold mines in its vicinity, on the rivers Mica and Bola, branches of the Bluefields, were worked by the early Spanish settlers, and are still worked by the Indians. The gold appears to be obtained from decomposed auriferous slates, which are ground by arrastres. In the same region are found veins of silver ores. Near Lake Nicaragua a bed of coal has been opened, which is probably of the nature of the tertiary coals of South America. Among the mountains are vast plains covered with grass, which gives support to immense herds of cattle and horses. Much good timber is found in the vicinity of the mines, among which are species of oak and pine. Fruits of the tropics grow abundantly in close proximity to those of the temperate zones, and the articles necessary for subsistence are easily obtained in the greatest abundance. The district is easily accessible from the lakes.

CHOPIN, Frédéric François, a Polish pianist and composer, born at Zelazowa-Wola, near Warsaw, Feb. 8, 1810, died in Paris, Oct. 17, 1849. His father was French, his mother Polish. His education in music was begun at the age of nine, and was for seven years conducted by Zimny, and subsequently by Elsner. Prince Anton Radziwill was his patron, and introduced him into the best society in Warsaw. He made several journeys to Germany to study the masterpieces of his art, and was at Vienna when the Polish revolution of 1830 broke out. Here he gave several concerts, but the public was absorbed in politics, and his success was

not great. He set out for London, but stopped at Paris, where he won immediate and brilliant fame as a composer, and performed in private concerts, but rarely appeared in public. For ten years previous to 1844 he gave only a single concert. In 1836 he formed an intimacy with Mme. Dudevant (George Sand). His health, always fragile, required a southern climate, and in 1837 they took up their residence in the island of Majorca, where she nursed him through a long and dangerous illness. The intimacy continued till 1847. In the spring of 1848 he made his long-projected visit to England, where he met with an enthusiastic reception. Contrary to his former habits, he entered much into society, and performed frequently at private concerts, but only three times in public, the last being at a concert for the benefit of the Poles. He returned to Paris utterly broken in health, and thenceforth incapable of any continuous labor. He had projected a book upon the theory and art of music; but only a few pages of it were written, and these were destroyed with all his unfinished works. As a composer Chopin ranks in the first class, although he produced no great continuous work. Liszt, his friend and admirer, gives an elaborate analysis of the character of his works: "We meet with beauties of a high order, expressions entirely new, and a harmonic tissue as original as erudite. In his compositions boldness is always justified; richness, even exuberance, never interferes with clearness. Daring, brilliant, and attractive, his works disguise their profundity under so much grace, their science under so many charms, that it is with difficulty we free ourselves sufficiently from their magical enthrallment to judge coldly of their theoretical value." This refers especially to the earlier compositions, "written in the commencement of his career, and characterized by a youthful vigor not to be found in some of his subsequent works, even when more elaborate, finished, and richer in combinations; a vigor which is entirely lost in his latest productions, marked by an over-excited sensibility, a morbid irritability, and giving painful intimations of his own state of suffering and exhaustion. His nocturnes, ballads, impromptus, and scherzos are full of refinements of harmony never heard before; bold, and of startling originality. His concertos and sonatas are beautiful indeed, but we may discern in them more effort than inspiration. Some of these efforts, however, are resplendent with a rare dignity of style; and passages of exceeding interest, beauty, and grandeur may be found among them." A complete list of the works of Chopin is given in Lowinski's *Musiciens polonais et slaves*. His life by Liszt, which is critical rather than biographical, has been translated by Martha Walker Cook (Philadelphia, 1863). His life has also been written by Barbedette (20th ed., 1869).

CHOPTANK RIVER rises in Kent co., Delaware, flows S. W. into Maryland, and near the

S. extremity of Talbot co. spreads into an estuary several miles wide and nearly 20 m. long, through which it flows into Chesapeake bay; total course, 100 m. It is navigable for sloops to the mouth of Tuckahoe river, a distance of about 50 m.

CHORAGUS (Gr. *χορός*, chorus, dance, and *ἀγειν*, to lead), a functionary among the ancient Athenians who paid the expenses attendant on the equipment and instruction of a chorus. Originally, the chorus in dramatic representations was selected from the citizens of the state; but, as music and dancing became more artistic, there arose the distinction between spectators and performers. Salaried artists were employed, and at length the entire superintendence of all the details of a theatrical representation was intrusted to a single individual, called the choragus, who was selected by the state, and upon whom rested all the expenses incurred in bringing out the show. Each of the ten tribes furnished a chorus of dancers and musicians, and chose a citizen to fulfil the duties of choragus. The person thus elected immediately assembled the performers, gave them an instructor, furnished them with costumes, and, during the time of their training, supported them at his own expense, providing them only with such food and drink as would strengthen or improve the voice. The choragi drew lots for the choice of teachers; for, as their credit depended upon the success of their chorus in the dramatic or lyrical contests, the selection of the instructor became a matter of great importance. The office of choragus was one of high dignity; for religion and art, and the rivalry between tribes and states, exalted the Athenian imagination; and the choragus who was adjudged to have exhibited the best entertainment received as a prize a tripod, which was ceremoniously consecrated in the temples, and on which was inscribed the name of the victorious choragus and of his tribe. There was a whole street at Athens formed by the line of these tripod temples. The term choragus came in time to signify a person who supplied the costs for any purpose.

CHOREA. See *ST. VIRTUS'S DANCE*.

CHORIS, Louis, a Russian painter and traveler, born of German parents at Yekaterinoslav, March 22, 1795, died at Jalapa, Mexico, March 22, 1828. He accompanied Biberstein to the Caucasus in 1813, and sketched the most beautiful plants of that region. In 1814 he joined Kotzebue in his voyage of circumnavigation. In 1819 he went to Paris, and engaged in the publication of the *Voyage pittoresque autour du monde* (Paris, 1821-'3), of which his drawings formed the most valuable part, the text being by Cuvier and Chamisso, with phrenological dissertations by Gall. His *Vues et paysages des régions équinoxiales* (Paris, 1826) was the complement of this work. He also studied historical painting in the studios of Gérard and Regnault, and assisted the former upon his "Consecration of

Charles X." Having undertaken a new exploration of Mexico and Central America with an Englishman named Henderson, he was murdered by highwaymen near Jalapa.

CHORLEY, a town of Lancashire, England, on the Cham, near its confluence with the Yarrow, 20 m. N. W. of Manchester; pop. in 1871, 19,824. It is situated on rising ground, is well built, and has been considerably improved within the present generation, an extensive system of sewerage having been in operation since 1857. The ancient parish church of St. Lawrence has been enlarged and renovated. There are numerous schools, a lyceum, and various educational and charitable institutions. A new cemetery, covering 13 acres, is provided with Gothic chapels for the use of Protestants and Roman Catholics. The population has risen from about 4,000 in 1801, owing to the remarkable progress of industry. Besides the staple manufactures of cotton fabrics, muslins, jaconets, fancy articles, and yarns, there are printing and bleaching, dyeing and chemical, boiler and engineering works, and iron and brass founderies. In the vicinity are mines of coal, lead, and iron, and quarries of slate and grit stone. Weekly markets are held on Tuesday, and annual fairs for cattle and horses, and for general purposes of trade. The Liverpool and Leeds canal passes within half a mile of the town, and is joined at a short distance by that from Lancaster and Preston.

CHORLEY, Henry Fothergill, an English musical critic and author, born near Billinge, Lancashire, Dec. 15, 1808, died in London, Feb. 16, 1872. In his boyhood he entered a mercantile establishment in Liverpool, but soon went to London to try a literary life. He had acquired a slight knowledge of music from Zengheer Hermann, the conductor of the Liverpool philharmonic society, and after a hard struggle attracted the notice of the editors of the "Athenæum," who gave him a position on that journal, of which he conducted the musical department for 35 years, with an honesty and candor never impeached even by those who differed with his judgment. When Gounod vainly sought a hearing in London, Chorley pleaded his merits so persistently that the composer was given a trial, and "Faust" met with a splendid success. During his long connection with the "Athenæum" Chorley found time to do much other literary work. Besides his books, he wrote a number of operatic librettos; among which were the "Amber Witch," for Wallace's music; the "May Queen," set by Sir Sterndale Bennett; "St. Cecilia," set by Sir Julius Benedict; "Kenilworth" and the "Sapphire Necklace," written for Arthur Sullivan; and "Faust" translated from and adapted to the music of the French score. His songs, which are numerous, all exhibit culture and refinement. In his translations he was generally remarkable for original treatment rather than fidelity. A short time before his death he nominally closed his connection with the "Athenæum," but continued to

write for it occasionally. His principal published works are: "Conti the Discarded, and other Tales" (3 vols., 1835); "Sketches of a Seaport Town," a novel (3 vols., 1835); "Memorials of Mrs. Hemans" (2 vols., 1836); "Lion, a Tale of the Coteries" (3 vols., 1839); "Music and Manners in France and Germany" (3 vols., 1841); "Pomfret, a Novel" (3 vols., 1845); "Criticisms on Modern German Music" (2 vols., 1854); and "Thirty Years' Musical Recollections" (2 vols., 1862).—Mr. Chorley's "Autobiography, Memoirs, and Letters," compiled by H. G. Hewlett, was published in 1873 (2 vols., London).

CHORON, Alexandre Étienne, a French musician and author, born at Caen, Oct. 21, 1771, died in Paris, June 29, 1834. He invented a system of notation in order to preserve the songs which he heard or composed. He afterward studied music under the best masters, but was equally interested in the physical sciences and mathematics. In 1794 he was appointed chief of brigade to the polytechnic school, where he passed several years. In 1815 he became director of the opera, which office he held for only 17 months. He founded in 1817 a musical school for children, which afterward took the name of *Institution royale de musique religieuse*. His most important work is his *Principes de composition des écoles d'Italie*. He left many others unfinished, among them a *Dictionnaire historique des musiciens*.

CHORUS (Gr. *χορός*), originally a dance in a ring, or round dance; then any dance accompanied by music, or choral dance. The chorus was an integral part of the Grecian drama, both tragic and comic, and was developed with it from its first rudiments in the religious processions in honor of Bacchus, with dithyrambic songs, dances, jokes, the wagon and sacred goat, through the improvements of Thespis (about 530 B. C.), who created a kind of stage, and introduced an actor reciting in monologues the deeds of the gods and heroes, and through those of Æschylus, who added another actor, shortened the songs and dances, and introduced the dialogue, down to the sublime creations of Sophocles and Euripides. The chorus, being of Doric origin, maintained its solemnity in form, and even in dialect. In its final state it was, in the tragedy, a group of persons of both sexes, the elders of the people, priests, counsellors of the king, matrons, captive virgins present as spectators at the scene of the action, representing to some extent in their lyrical utterance the emotions and thoughts of the audience. When the actors paused, the chorus sung or spoke, accompanied by solemn music, sometimes only through their leader, called the coryphæus, sometimes through different parts addressing each other and replying, while moving from one side of the stage to the other, in so-called strophes (turns), antistrophes (counter-turns), and epodes (after-songs), enhancing the impression of the action by their remarks, by expressions of joy, sorrow, admiration, or horror, as caused by the things seen; by hymns of

thanks, or supplications to the gods; or addressing the heroes of the scene, advising or consoling, warning or approving in moralizing strains. It was thus that the chorus, standing between the heroes and the people, reflected as a mirror the conscience of the former and the consciousness of the latter, both affected by mighty events and tragic developments. The chorus thus forms the distinctive feature of the ancient drama, whose imitation has often, and almost always unsuccessfully, been attempted by modern poets, as for instance by Schiller in his *Braut von Messina*. The tragic chorus, in the periods subsequent to Æschylus, usually consisted of 15 members; the comic of 24. That Æschylus employed choruses of 50 is believed by some critics, but considered improbable by others. In the comic or satirical drama the chorus consisted of satyrs, and had its songs and dances mostly of a frivolous character. The providing for the choruses, the equipment and instruction, was in Athens an honorable though burdensome office, called *choragia*. (See *CHORAGUS*.)—In modern music, a chorus is a composition in several parts, each of which is to be sung by a plurality of voices, while all the parts are to be combined together in one simultaneous performance. The term is also applied to the performers who sing these parts. In operas and oratorios the chorus is indispensable to afford relief to the solos, duets, trios, and the like, as well as to express the culmination of any sentiment or passion; and composers have often made use of it with the happiest effect where the orchestra or single voices would prove totally inadequate. In secular music, the "Conjuration" chorus in Rossini's "William Tell," and the "Benediction of the Poniards" in Meyerbeer's "Huguenots;" and in sacred music, the choruses in Handel's oratorios, and particularly in the "Messiah," are admirable specimens of this form of composition, and when well performed, with full orchestral accompaniments, produce the most sublime and thrilling effects of which music is capable.

CHOSE IN ACTION, that species of property which, in distinction from property in possession, consists in the right to reduce something of value to possession by means of some legal remedy. Thus, the right to recover money due on a bond is a chose in action, of which the bond is the evidence; and the right to recover damages for the unlawful conversion of one's property by another is also a chose in action. Formerly the law did not recognize a quality of assignability to such rights, but an exception was made of bills of exchange and promissory notes payable to order or bearer, and which in technical language were called negotiable; and the courts of equity went further, and protected the rights of assignees in all cases where the demand was for money due by contract express or implied, or for the conversion of property. And now the courts of law also recognize and protect the rights of as-

signees; but except in the case of negotiable paper, and such other cases as statutes may have provided for, the assignee, if he prosecutes, must do so in the name of the assignor.

CHOSROES, or **Khosru**, the name of two kings of Persia. **I.** Surnamed by historians the Just, by those of his nation Nushirvan (noble spirit), one of the most remarkable monarchs of the East, reigned from A. D. 531 to 579. He was of the house of Sassan, and the son and successor of Cabades or Kobad. In his youth he exhibited those qualities which afterward gained for him the title of "generous," and this is said to have rendered him the object of his father's predilections to the succession in preference to his two elder brothers; he appointed him king over one of his provinces, by which according to Persian usage he was designated as successor, and, in order to strengthen his choice, called on the Greek emperor to adopt him. The proposal was accepted, and Chosroes departed for Constantinople; but a puerile disagreement caused a rupture, the return of the prince, and perhaps his constant hatred to the Greeks. The last war of his father he terminated gloriously by a treaty of peace, in which Justinian promised to pay 10,000 lbs. of gold. Chosroes now directed his attention to the regulation of the affairs of his kingdom, which during his father's reign had been distracted by a long war with the Byzantine empire, and by civil and religious commotion; suppressed the sect of the followers of Mazdak, whose communistic theories in regard to property and marriage had been a source of disturbance; and appointed four viziers to rule the four great divisions of the state, Assyria, Media, Persia, and Bactriana. He extended its limits to the Indus and Oxus, and compelled the nomadic tribes of the northern barbarians to repress the latter river. But his chief wars were those against the Greeks. Viewing with concern the victories of Belisarius, the great general of Justinian, over the Vandals in Africa and the Goths in Italy, he roused his vassal the Arab Almondar, prince of Hira, to make an inroad into the empire, and soon afterward hostilities broke out between Persia and the emperor. Chosroes invaded Syria (540), plundered its cities, and took Antioch after a brave resistance. Belisarius, sent to defend the eastern provinces of the empire, was successful, but soon fell a victim to the intrigues of the court and was recalled, and Chosroes was again victorious. The war was continued for a series of years, chiefly in the districts east of the Black sea, and terminated by the peace of 562, by which the emperor bound himself to pay an annual tribute of 30,000 pieces of gold, and received the cession of the Persian claims upon Colchis and Lazica. This peace continued for ten years; but the conquest of Yemen in southern Arabia by the lieutenants of Chosroes, who wrested it from the Abyssinians, the allies of the Byzantine empire, incited Justin, the new emperor, to collect a great army and recom-

mence hostilities. He was defeated, and the Persians plundered Syria again. Tiberius obtained a truce of three years; this he employed in preparing a great army, and in the bloody battle fought near Melitene, in Lesser Armenia, the old Persian monarch was completely defeated (578). He died soon after, and was succeeded by his son Hormisdas (or Hormuz) IV.—The 48 years of Nushirvan's reign formed the golden age of modern Persia, in the history and poetry of the East. Dreaded by his enemies, he was revered and beloved by his subjects, who enjoyed the fruits of his victories and admired his justice; easily forgiving those crimes which served to confirm his throne, such as the murder of his two elder brothers, and the extermination of their families and adherents. His government was firm, vigorous, and impartial; the administration of justice was watched most scrupulously and severely; the poor were the particular objects of attention; orphans were educated at the public expense; the provinces were often visited by the monarch; the ancient religion of the Magi was respected; science and literature, trade and agriculture were zealously promoted; academies and libraries were founded, and enriched with the annals of the kingdom, as well as with translations from the Sanskrit, Greek, Latin, &c., among which the celebrated fables of Pilpay or Bidpay, expressly sent for to India, have become a literary monument even in the West. The wisdom of Nushirvan was admired by philosophers from Greece, and embassies were sent to him from Africa, India, China, and Thibet. **II.** Surnamed Parviz, grandson of the preceding, succeeded his father Hormisdas, who was deposed in 590. Prevented from occupying the throne by the rebel Bahram, he fled to the Greek emperor Mauritius, entreated his assistance, returned with an army, and defeated the usurper. Bahram escaped to Turkistan, where he perished soon after. In a treaty with Mauritius he rewarded his aid by a large sum of money, and the surrender of the most important cities of Mesopotamia. He continued in peace with Constantinople during that emperor's life, and kept a Greek body guard, so that Persia was in a considerable measure under Greek influences. His ally having been assassinated by Phocas (602), he took up arms against the empire with the ostensible purpose of avenging his death. A long war ensued, in which nearly all the Asiatic provinces of the Greeks were devastated and conquered, and which was not interrupted by the death of Phocas, or by the supplications for peace of Heraclius. Antioch, Cæsarea in Cappadocia, the whole of Palestine, Egypt with Alexandria, and Asia Minor, were wrested in successive campaigns from the new emperor; his capital, deprived of its supplies from Egypt, was a prey to famine, and threatened from the north by the Avars and other barbarians. Threatening to pass the Bosphorus and besiege Constantinople, Chosroes proposed

ignominious conditions of peace, which were rejected by Heraclius, and the war recommenced. The military glory, the pride and splendor of the Persian monarch had now attained their zenith. Master of western Asia, he oppressed the Christian inhabitants of the Byzantine provinces, and adorned with the spoils of the conquered his favorite residence, Dastagerd, east of the Tigris, about 60 m. from Ctesiphon, the capital. Its marvellous beauty and pomp have been extolled by visitors and poets, and even grave historians speak minutely of its paradise, or park, containing pheasants, peacocks, ostriches, roebucks, and wild goats; of its lions and tigers, destined for the pleasures of the chase; of the 960 elephants, 20,000 camels, 6,000 mules and horses, kept for the service of the camp and to carry the royal tents; of the 6,000 guards that watched before the gates; of the 12,000 slaves and 3,000 women subjected to his caprices or passions; of the precious metals, gems, silks, aromatics, in a hundred subterranean vaults of the palace; of its 30,000 hangings, 40,000 columns, and its cupola with 1,000 globes of gold imitating the motions of the planets and the constellations of the zodiac. But in the midst of all this greatness Chosroes was summoned in a letter from Mecca to acknowledge Mohammed the prophet of Allah. He tore the letter and rejected the proposal; upon which Mohammed is said to have exclaimed, "Thus will God tear his kingdom and reject his supplications." The first part of this prophecy was soon fulfilled by the victories of Heraclius, who in a series of brilliant campaigns (622-627) reconquered all the lost provinces of the empire, repeatedly defeated Chosroes, advanced to the Tigris, and finally won the great battle of Nineveh; after which the pusillanimous but proud and obstinate monarch fled with his favorite wife Sira, the Shirene of Persian poetry, and escaped the hands of his enemy only to be murdered at the command of his son Siroes, after having witnessed the massacre of his numerous sons, and suffered the horrors of a dungeon (628). Chosroes II. was the last mighty king of the house of Sassan; his son enjoyed the fruits of his unnatural deed only for eight months; and, after a few years of civil wars, Persia was conquered by the Arabs.

CHOTEAU, a N. county of Montana, bordering on British America; area, about 12,500 sq. m.; pop. in 1870, 517. It is drained by Milk river, by the Missouri, and by Dog, Judith, Arrow, Teton, and Bear's or Maria's rivers, affluents of the Missouri; Medicine or Sun river forms a portion of the S. boundary. The Bear's Paw, Little Rocky, and Judith mountains lie wholly or partly in the county. Some gold has been found, and coal is abundant. The estimated value of farm productions in 1870 was \$1,647, and of live stock \$6,000. Capital, Fort Benton.

CHOUANS, a name given to the royalist peasantry of Brittany and Lower Maine, in France,

who, following the example of the Vendéans, rose in arms against the revolutionary government as early as 1791, and who often, under the pretence of waging war in the king's behalf, infested the roads, pillaged villages, and committed all sorts of depredations. The name was ultimately extended to all the insurgents in western France. The rebellion in Lower Maine had been prepared by a number of contraband salt makers, among whom four brothers, named Cottereau, were conspicuous. The taciturnity of their grandfather had given him the nickname of *Chat-huant* (screech-owl), or *Chouan* according to the Bas Breton dialect. This nickname had been transmitted to the grandsons, who were usually called the "brothers Chouan." Jean, the eldest and boldest of the four, had once been sentenced to death, and, having through the entreaties of his mother obtained his pardon from Louis XVI., had become an ardent royalist. His earliest companions were a lame beggar surnamed *Jambe d'Argent* (Silver Leg), Tristan l'Hermite, Taillefer, Coqueureau, and a few others. Their first encampment was established in an excavation in the woods of Mison; and they began to appear in villages where revolutionary opinions prevailed, against detachments of troops and national guards. The *Chouannerie*, as these warlike bands were soon called, was not limited to a single province; from Lower Maine it extended through Brittany, where it gained a strong foothold, and thence eventually to Normandy. The Chouans received powerful accessions from the ranks of the peasants, driven to rebellion by heavy taxes, by persecution of their religion, or by fear of being enrolled in the army. The first serious outbreak in Brittany (Feb. 13, 1791) was occasioned by the attempted removal of the bishop of Vannes, who had refused to take the civil oath; the peasants of Sarzeau came forward to protect him, but were fired upon by troops of the line and national guards. Thenceforward Brittany was divided into two camps, the adherents and the opponents of the government. The military organization of the Chouans was gradually perfected, and they soon numbered no less than 100,000 volunteers, who were subsequently distributed into five distinct corps; but for the sake of efficiency they generally moved in bands of 25, 50, and sometimes 100 men, acting independently, but according to a common direction. In 1793, under the name of the Little Vendée, the Chouans joined the great royalist army. On this occasion it was proposed to invest one of the royalist generals with the command of the Chouans, but the reply was: "We have come with Jean Chouan, we know no one but him; we obey him through friendship; he must be our leader; if not, we will depart." Consequently Cottereau reassumed the command of his forces, which he kept until July 28, 1794, when he was killed in an encounter with republican troops. Tactics and regular evolutions were not in accordance with

the instincts and habits of these partisan bands. Consequently, after the heavy loss experienced by the royalist army near Le Mans, and especially after their bloody defeat at Savenay, Dec. 27, 1794, the Chouans returned to their haunts, and resumed their guerilla warfare. Detachments of troops were overtaken or slaughtered, stage coaches were arrested on the highway, receivers of public money were carried off and tortured, and the chiefs were powerless to prevent these excesses. On the death of Cottereau, Jambe d'Argent had become one of their leaders; but the most popular was Georges Cadoudal, who had then taken up his abode in Lower Brittany, and waged unrelenting war against the republican troops. Some attempted to bring about a pacification by a treaty concluded at La Mabilais; but this was rejected by Cadoudal and other influential Chouans. Even the disaster of Quiberon, July 16, 1795, was unable to shake their power. The loss of that disaster had fallen on the *émigrés* and the English, while the royalist peasantry had suffered little. They not only kept in arms, but their chiefs tried to reënforce their organization and to bring about insurrection in several other provinces of France. Their efforts were in some measure successful, and would have been completely so if any prince of the Bourbon family had dared to land in Brittany and put himself at the head of the movement. The count d'Artois indeed cruised off the coast of France for a few days in August, 1795, and this alone was sufficient to give a new impulse to royalist ardor; but the disappointment caused by his sudden departure crushed the hopes of the most zealous. Some chiefs and several bands still persisted, but the great army of the Chouans dwindled away, disgusted at serving princes by whom they were sacrificed. The most obstinate joined the *émigrés* in several conspiracies. Cadoudal was arrested and executed in 1804, and the Chouannerie may be said to have died with him.

CHOUGH (*coracia gracula*, Linn.), a bird of the crow family, sometimes called Cornish daw, and red-legged crow. It is a native of Europe, and is most numerous on the bold rocky shores of Cornwall, Devonshire, Wales, and the Hebrides islands; on the continent it prefers the Alpine regions. The plumage of the adult male and female is black, glossed with purplish blue and green; the legs, feet, and bill are red; the claws black, strong, and hooked; the bill is longer than the head, arched and tapering to an acute point; the wings are about the same length as the tail, which is even, with a small tip; on the head and neck the plumage is blended and highly glossy. The length to the end of the tail is 17 in.; extent of wings 34 in.; tail $6\frac{1}{2}$ in.; bill $2\frac{1}{4}$ in.; tarsus $2\frac{1}{8}$ in.; weight about 14 oz. The female is somewhat less in size, and has a shorter bill. When seen at a distance, the chough resembles the rook, which it excels in elegance of form; near at hand, the red bill and feet readily dis-

tinguish it. It is gregarious like the rook and jackdaw, both of which it resembles in its note and mode of flying. Its food consists of insects, grubs, seeds, and the flesh of dead animals; it is particularly fond of grasshoppers and cockchafers, for which it scratches fields and rocky places, walking like the rook. It is very shy, unless in the breeding season; its flight is high, irregular, and performed by slow motions. It breeds near the sea in rocks, caverns, and ruined towers; the nest is composed of sticks, and lined with wool and hair; the eggs are generally five in number, of a dull white color, with light brown and ash-colored spots, chiefly at the larger end. In confinement the chough becomes very tame and docile; it is very crafty, hiding its food, and frequently articles of value which it has stolen, and as the bird always selects elevated positions, it is often difficult to recover them. It

Chough (*Coracia gracula*).

eats little at a time and regurgitates its food like ruminating quadrupeds; even when full fed, it will try to throw up a portion of its meal in order to take a little more. It is capable of very strong attachments and dislikes.

CHOULES, John Overton, D. D., an American clergyman, born in Bristol, Eng., Feb. 5, 1801, died in New York, Jan. 5, 1856. His parents were members of the Wesleyan connection; but he united with the Baptist church, and in 1822 became a student of divinity in the Baptist college at Bristol. Having completed his theological course, he emigrated to America in 1824. The first winter after his arrival in New York was spent in supplying various churches in that city and vicinity. In the spring of 1825 he became principal of an academy at Red Hook, N. Y. In September, 1827, he was ordained as pastor of the second Baptist church in Newport, R. I. After a pastorate of about six years, he accepted the call of the first Baptist church in New Bedford, Mass. In 1837 he became pastor of the Washington street church, Buffalo, in 1841 of the Sixth street Baptist church, New York, and in 1843 of the Baptist church at Jamaica Plain, near

Boston. In 1847 he resumed the pastorate of the second church in Newport, and in 1854 accompanied Mr. Vanderbilt in his steam yacht on a voyage to Europe. He was the author of two volumes of travels, entitled "Young Americans Abroad" and "The Cruise of the North Star." Besides these volumes, he completed Smith's "History of Missions" (2 vols. 4to, 1832); wrote a continuation of Hinton's "History of the United States;" and edited Neal's "History of the Puritans," Forster's "Statesmen of the Commonwealth in England," and James's "Church Members' Guide."

CHOUTEAU. I. Auguste, an American pioneer, born in New Orleans in 1739, died in St. Louis, Feb. 24, 1829. He and his younger brother Pierre were the founders of the city of St. Louis, and their lives were closely connected. **II. Pierre**, brother of the preceding, born in New Orleans in 1749, died in St. Louis, July 9, 1849. In August, 1763, the two brothers joined the expedition of Laclède, under a commission from the director general of Louisiana, to establish the fur trade in the region west of the Mississippi river, and bordering on the Missouri and its tributaries. Auguste was intrusted by Laclède with the command of the boat. They reached the settlement of St. Genevieve in November, being just three months ascending the river from New Orleans. In the winter they selected a point 61 m. above St. Genevieve, on the western bank of the Mississippi, for their principal post, and named this St. Louis. Auguste Chouteau was in charge of the party that commenced operations here, Feb. 15, 1764. Speaking of the brothers in his "Sketch of the Early History of St. Louis," Nicollet observes: "These two young men, who never afterward quitted the country of their adoption, became in time the heads of numerous families, enjoying the highest respectability, the comforts of an honorably acquired affluence, the fruit of their own industry, and possessed of a name which to this day (1842), after a lapse of 70 years, is still a passport that commands safety and hospitality among all the Indian nations of the United States, north and west." Both were prominent men, and officers ranking as colonels in the early history of St. Louis. **III. Pierre**, son of the preceding, born in St. Louis, Jan. 19, 1789, died there, Sept. 8, 1865. He was at first a clerk with his father and uncle, who were then largely engaged in the fur trade with the Indians, but soon entered into business for himself. Following the Indians as they receded from point to point, he at different times established himself at what are now St. Joseph, Kansas City, Bellevue, Council Bluffs, Fort Pierre, Fort Berthold, Fort Union, at the mouth of the Yellowstone river, and Fort Benton, at the head of navigation of the Missouri. As early as 1806 he went up to Dubuque to trade with the Sacs and Foxes, ascending and descending the rivers in canoes. He also followed the Indians as they receded up the

Osage river, and up the Mississippi from Keokuk to St. Paul, having trading posts all along the rivers. In 1834 he and his associates purchased the interest of John Jacob Astor in the American fur company; and in 1839 they formed the trading company which, under the firm name of P. Chouteau, jr., extended its operations southward as far as the Cross Timbers in Texas, northward to the falls of St. Anthony, and northwestward to the Blackfeet country, monopolizing the fur trade of the entire region east of the Rocky mountains, and also controlling the trade with Santa Fé in New Mexico. This business involved large transactions in the eastern cities and in Europe, and for many years Mr. Chouteau resided in New York. In 1819 he was a member of the convention which framed the first constitution for the state of Missouri, but with this exception he never engaged in politics.

CHOWAN, a N. E. county of North Carolina, bounded S. by Albemarle sound, and W. by Chowan river, a broad arm of the sound; area, about 240 sq. m.; pop. in 1870, 6,450, of whom 3,369 were colored. It was one of the original precincts of the lords proprietors under King Charles II., and was occupied by a tribe of Indians called Chowanokes. The surface is slightly uneven, and the soil generally of good quality. The chief productions in 1870 were 9,176 bushels of wheat, 137,647 of Indian corn, 41,130 of sweet potatoes, and 1,331 bales of cotton. There were 451 horses, 637 milch cows, 1,177 other cattle, and 5,829 swine. Capital, Edenton.

CHRÉTIEN (or Chrestien) DE TROYES, a French poet, born probably at Troyes about 1150, died near the close of the 12th or in the beginning of the 13th century. Of his life little is known, except that he was one of the most learned men and gifted trouvères of his day, and that he acquired great celebrity in France, Germany, and other parts of Europe. As some of his works were dedicated to Philippe of Alsace, count of Flanders and Vermandois (1168-'91), he is supposed to have been the laureate at that court. Some works written by others have been attributed to him, while some of his genuine works, including *Tristan*, or *Del roi Marc et d'Ysolt la blonde*, and the *Chevalier à l'épée*, are apparently lost. His fame rests upon six romances, which are extant in French libraries, with the exception of *Li romans dou chevalier au Lyon*, published by Holland (Hanover, 1862), which served as a basis for Hartmann's *Von Aue Iwein*. His other works are: *Iric et Enide*, or *Li contes d'Erec* (published in Haupt's *Zeitschrift für deutsches Alterthum*, Leipsic, 1855; reproduced in Hartmann's *Von Aue Erec*); *Lancelot du lac ou de la Charette*, or *Li romans del chevalier de la Charette* (continued by Godefroy de Laigny, published by Jonckbloet, the Hague, 1850); *Cliget, chevalier de la table ronde*, or *Li contes de Cliget*; and, the most celebrated of them all, *Perceval le Gal-*

lois, or *Li contes del Graal* (with continuations by Gautier de Denet, Gerbert, and Manesier). The last two have not yet (1873) been printed; but his *Contes del roi Guillaume d'Angleterre* were published by Michel in his *Chroniques anglo-normandes* (3 vols., Rouen, 1840), and served as a basis for O. Schönhut's *Historie von König Wilhelm und seinen Söhnen* (Reutlingen, 1852).

CHRISM (Gr. *χρίσμα*, ointment), in the Roman and Greek churches, ointment consecrated by the bishops, and used in the administration of baptism, confirmation, ordination, and extreme unction. There are two sorts of chrism used in the Roman church: one made of olive oil and balsam, which is used in baptism, confirmation, and in conferring orders; the other is composed only of oil, and is used in extreme unction. These are always blessed by the bishop on Maunday Thursday, and each priest is required to obtain a fresh supply and burn the old oils. In the Greek church, besides the oil and the balsam, it is usual to employ 35 kinds of spices. The Maronites formerly used balsam, musk, cloves, incense, roses, and other substances.

CHRIST (Gr. *χριστός*, anointed), a title applied in the New Testament to Jesus, and derived from the ancient practice of consecration by anointing to the regal, prophetic, and sacerdotal offices. The practice is still preserved in the consecration of kings. The apostles designate Jesus by his official title much more frequently than by his historical name. The reverse is the practice of the evangelists. (See **JESUS CHRIST**.)

CHRIST, Pictures of. Among the early Christians, the aversion to the fine arts, as practised by pagan nations, was so great, that no pictorial representation of Jesus Christ was ventured upon, except symbolically through the signs of the lamb, the vine, and fish; the Greek term for fish, *ἰχθύς*, constitutes the initial letters of the following Greek sentence, significative of Christ's mission, *Ἰησοῦς Χριστὸς Θεοῦ Υἱὸς Σωτήρ*, thus establishing a monogram, which has acquired a sacred celebrity. The earliest artistic effort to commemorate the life of Christ is parabolical, namely, representing him as a shepherd among his flock, with a shepherd's flute; also in search of the lost sheep, or carrying it after having found it. In these representations, which abounded at the time, Christ appears with the ideal attributes of a youth; also in some instances in the maturity of manhood. Accounts have come down to us of pictures of Christ in the possession of King Abgar of Edessa and of St. Veronica, also of one ascribed to St. Luke; but these accounts are as little supported by historical evidence as the tradition of a miraculous picture at Berytus, and of a statue erected to his memory by the woman whom he had restored to health. The *Veronica*, also known as the *Ecce Homo*, is said to be the impression taken on a linen cloth which a woman named Ve-

ronica offered to the Saviour to wipe his face, while on his way to crucifixion. The original miraculous picture is said to have been preserved in St. Peter's church in Rome as late as about the year 700. The most ancient portrait of Christ was in the possession of the emperor Alexander Severus. In the *Museo Cristiano* of the Vatican is another picture of the Saviour, also dating from the 3d century, worked in antique mosaic, ascribed to a pagan artist, and representing the Saviour as a philosopher. Equally ancient portraits of Christ are found in the Calixtinian and Pontian catacombs near Rome, and are contained in Aringhi's *Roma Subterranea Nova*. Here Christ is represented with an oval face, straight nose, arched eyebrows, and high forehead. The expression is solemn, yet tender. The light brown hair, parted in front, descends in long curls upon the shoulders; the beard is rather short and unequal. A writer of the 8th century, John of Damascus, represents Jesus as having been of imposing presence, with bushy eyebrows, singularly beautiful eyes, regular nose, curling hair, black beard, yellow complexion, resembling the Virgin Mary, &c. A supposititious letter, purporting to have been written by Lentulus, Pilate's predecessor, to the Roman senate, also represents him as having possessed great personal beauty; but this letter is now known to have been written in the 14th century, and to have been based upon the portraits in the catacombs. The pictorial representations of the head of Christ, which made their first general appearance toward the end of the 4th century, and which served as types during the middle ages, were taken from the impressions traceable to these descriptions, and which, however conflicting in details, were all agreed in the general attributes of beauty in Christ's appearance. From the early middle ages down to Michel Angelo and Raphael, we find the same original conception guiding the minds of artists. Raphael's "Christ in the Sepulchre," and Leonardo's in the "Holy Supper," are generally considered the most beautiful pictures of Christ extant. Titian also excelled in this branch of sacred art; his head of Christ in the "Tribute Money" in the Dresden gallery is his best. Among subsequent artists, Ludovico Carracci's heads of Christ are full of expression.—See Grimm's *Die Sage vom Ursprung der Christusbilder* (Berlin, 1843).

CHRISTCHURCH, a parliamentary and municipal borough, town, and parish of Hampshire, England, 20 m. S. W. of Southampton; pop. of the parliamentary borough in 1871, 15,415. It is 7 m. from the Christchurch station on the Southampton and Dorchester branch of the Southwestern railway, on the S. W. border of the New forest, at the confluence of the Avon and Stour, about 1½ m. above their mouth in Christchurch bay, an inlet of the English channel, about 11 m. long. It derives its name from a fine old church founded in early Saxon times, and rebuilt under William II. In

Christchurch bay a double tide occurs every 12 hours.

CHRISTCHURCH, a town of New Zealand, the capital of the province of Canterbury, on the banks of the Avon, about 7 m. from the sea, and about 9 m. from Lyttleton, which is its port; pop. of the town proper in 1871, 7,931; of the town and suburbs, 12,466. It is connected with Lyttleton by a railway tunnelled at great expense through the Lyttleton hills, and with all the principal towns of New Zealand by telegraph. It is the seat of an Anglican bishop, and has numerous fine buildings, among others the college, the supreme court, the immigration barracks, and the banks. It has also flourishing manufactories.

CHRISTIAN. I. A S. W. county of Kentucky, bordering upon Tennessee; area, 704 sq. m.; pop. in 1870, 23,227, of whom 9,812 were colored. It is watered by a number of small streams, several of which flow for 2 or 3 m. through subterranean channels. The soil in the southern and level part of the county is productive; the northern part is hilly, and its wealth consists chiefly in forests and mines of coal and iron. The Evansville, Henderson, and Nashville railroad passes through the county. The chief productions in 1870 were 242,980 bushels of wheat, 778,533 of Indian corn, 65,577 of oats, 2,353 tons of hay, 155,725 lbs. of butter, 28,727 of wool, and 5,384,137 of tobacco. There were 3,923 horses, 2,777 mules and asses, 3,325 milch cows, 5,004 other cattle, 11,942 sheep, and 26,561 swine. There were 6 grist mills, 5 saw mills, 1 distillery, 2 manufactories of furniture, and 4 of saddlery and harness. Capital, Hopkinsville. **II.** A central county of Illinois, bounded N. by Sangamon river, and intersected by the S. fork of that stream; area, 675 sq. m.; pop. in 1870, 20,363. It has a generally level surface, diversified by timber lands and fertile prairies. It is traversed by the Illinois Central, the Indianapolis and St. Louis, and the Springfield and Illinois Southeastern railroads, and the St. Louis division of the Toledo, Wabash, and Western. The chief productions in 1870 were 522,401 bushels of wheat, 1,883,336 of Indian corn, 383,821 of oats, 86,161 of potatoes, 22,964 tons of hay, 193,572 lbs. of butter, 63,247 of wool, 21,040 of honey, and 31,322 gallons of sorghum molasses. There were 9,229 horses, 4,470 milch cows, 7,991 other cattle, 15,585 sheep, and 35,015 swine. There were 2 manufactories of agricultural implements, 3 of bricks, 5 of carriages and wagons, 1 of sashes, doors, and blinds, and 7 grist mills. Capital, Taylorsville. **III.** A S. W. county of Missouri, drained by James river and branches of the White; area, 500 sq. m.; pop. in 1870, 6,707, of whom 114 were colored. The surface is undulating or hilly; the soil in the valleys is fertile. Timber is plentiful. The Atlantic and Pacific railroad passes through the N. W. extremity. The chief productions in 1870 were 56,574 bushels of wheat, 216,185 of

Indian corn, 45,260 of oats, and 16,132 lbs. of tobacco. There were 2,601 horses, 1,826 milch cows, 2,815 other cattle, 7,071 sheep, and 14,847 swine. There were 3 grist mills, 4 saw mills, and 2 wool-carding factories. Capital, Ozark.

CHRISTIAN, the name of nine kings of Denmark. Since 1448 the Danish kings (with the single exception of John, 1481-1513) have upon their accession to the throne assumed alternately the names of Christian and Frederick. The following are the more important of them. **I. Christian II.**, surnamed in his own country the Fiery, and in Sweden the Tyrant, son and successor of King John, born at Nyborg, July 2, 1481, died at Kallundborg, Jan. 24, 1559. His education was imperfect, and his habits became dissolute. At the age of 20 his father intrusted to him the repression of a rebellion in Norway, having previously placed him under the guidance of the bishop of Hammer. No sooner were they arrived in Norway than the prince destroyed the bishop's commission, and shut him up in a dungeon, where he soon died. Christian quelled the insurrection, nearly extirpated the Norwegian nobility, and carried fire and sword across the border into Sweden. During this expedition he met with the daughter of Sigbrit Willius, the hostess of a petty inn in Bergen. The daughter, known only as *Dyveke*, "Little Dove," was of wonderful beauty, and became Christian's mistress. Upon the death of King John (1513), during whose reign the union of Calmar had been re-established, Christian was crowned at Copenhagen and at Opslo (now Christiania) in Norway. At the time of his father's coronation at Stockholm, Christian was recognized by the Swedes as successor to the Swedish throne; but in the mean time successful rebellion had again partly emancipated Sweden from the Danish yoke. Christian, being about to invade Sweden, married Isabella, sister of the emperor Charles V. of Germany; but he still retained his mistress Dyveke, whose mother, a woman of singular talents, had already achieved a complete ascendancy over his mind. He invested her with the administration of the customs revenue, and with the collection of the tolls at Elsinore. She diminished many duties and taxes in order to encourage exportation; and this measure, of serious injury to the Hanse towns, was the cause of their alliance at this juncture with Sweden. Sigbrit also brought about many restraints upon the nobles and clergy, especially in monopolies which they enjoyed. In the fourth year of Christian's reign Dyveke suddenly died, probably by poison. Suspicion fell first upon members of the senate, who aimed to rid themselves of the influence exercised against them by Sigbrit; but afterward upon a young Dane, Torben Oxe, the master of the royal household. The youth had fallen desperately in love with Dyveke, and the tragedy followed, brought on probably by the despair of the guilty couple. Sigbrit, whose

influence had greatly increased, instigated the king to the most extreme cruelties. Meanwhile great preparation was made in Sweden to resist the Danish invasion. The Swedish administrator or regent, Sten Sturé, had appointed Gustavus Trollé to the archbishopric of Upsal. The new primate, still young, had completed his religious studies at Rome, and on his way home had met at Lübeck a confidential agent of Christian, who had little difficulty in obtaining a promise to support the pretensions of the king. Christian found means also to gain over to his cause, at least in appearance, the papal legate; but that personage disclosed to the regent the projects of Christian, as well as the treason of Trollé and of certain commanders of fortresses bribed by the Danes. The governors of the fortresses were arrested, and revealed the plot, which they said was directed by Trollé, who, disregarding a summons to appear before the diet, fortified himself in his castle. A Danish army, which had landed to relieve Trollé, was attacked by the regent and driven back. Sturé then forced the castle of the archbishop, compelled his abdication, sent him a prisoner to the monastery of Wodstena, and razed his castle to the ground. The pope placed Sweden under interdict. The regent and his followers were excommunicated, and condemned to pay to Trollé 100,000 ducats, and to rebuild his castle. The execution of the bull was intrusted to Christian, who besieged Stockholm with a powerful fleet and army, but was driven off by Sturé. Feigning a wish to treat, he obtained from the regent provisions for his fleet, and put in irons six Swedish nobles, among them Gustavus Vasa, who had been sent to him as hostages during the truce. These, he sent word to Sturé, should be put to death unless Danish authority were immediately accepted. The Swedes made a sharp attack, but the wind setting fair, Christian weighed anchor and sailed with his prisoners to Copenhagen. Next year he seized a quantity of copper belonging to the papal legate which was about to pass the strait at Elsinore. This, in addition to the payment by Charles V. of part of his sister's marriage portion, enabled him to resume his operations against the Swedes, and the expedition was embarked in January, 1520. At the first battle, fought at Bogesund, the Swedish regent fell mortally wounded. The Danes advanced by forced marches between the lakes Wenner and Wetter, and reached the forest of Tiwed, the ancient rampart of northern Sweden. Here the peasants made a desperate stand against the invaders, who however outflanked them, cut them to pieces, and gained the high road to the capital. A baronial diet, which had been convoked at Upsal, saw that resistance was hopeless, and entered into a convention with the Danes that Christian, on condition of a promise of general amnesty, should be crowned king of Sweden. Christian, who had remained at Copenhagen, signed the convention in that city

on March 31, 1520. Stockholm and Calmar, the two great fortresses of Sweden, still held out against the invaders, and were defended each by a woman. The widow of the regent, Christina Gyllenstjerna, refused to accept the treaty, and aroused the burghers of Stockholm to a desperate resistance. Lübeck and Danzic promised her assistance; and the peasants from the neighboring farms engaged to harass the enemy in the rear, but they had no leader. Christina held out for four months, when she was compelled to capitulate. Calmar shared the same fate, and in September Christian was everywhere acknowledged. He now resolved upon the extirpation of his enemies. As executor of the papal bull, he pretended that his promise of amnesty as king must not conflict with his duties as representative of the supreme pontiff. The coronation was solemnized in the presence of the Swedish nobles and clergy. Festivities followed during the next three days, when an assembly was held in the great hall of the palace. Christina was summoned to hear her husband denounced and reviled by the creatures of the king. His surviving adherents among the nobles were at once declared and condemned as heretics. The city gates were closed and guarded. Scaffolds and blocks arose during the night in the great square. The first head to fall was that of the venerable bishop of Strengnäs; immediately after him the bishop of Skara and 13 nobles, among whom was the father of Gustavus Vasa. For two days the butchery continued, and dead bodies lay in masses in the streets. The king at length permitted the corpses to be removed to an eminence outside of the city. Upon them he caused the remains of the regent and of his infant child to be flung; and then they were burned. The widows and daughters of the murdered men were abandoned to the soldiery. Christian travelled through the country, marking every stage of his journey with blood; whole families were extirpated. Gustavus Vasa had now escaped to Sweden, and, reaching the borders of Dalecarlia, had aroused the peasants of that province. He issued from the northern provinces at the head of 20,000 men, and went on from victory to victory. Christian summoned him, upon pain of the instant execution of his mother, who was imprisoned with his sisters at Copenhagen, to lay down his arms; he refused, and their death followed shortly afterward in their dungeon. Christian meanwhile, leaving the defence of Sweden to his generals, made a visit to his brother-in-law, the emperor Charles V., in the Netherlands, to solicit the arrears of his queen's dowry, and assistance in a quarrel with the duke of Holstein and the Hanse towns. He was received at Brussels with great magnificence, but obtained little or no satisfaction in his suit. His dominions now were everywhere distracted. Slaghöck, the king's confessor, had meanwhile been made archbishop of Lund; and there now arrived a papal nuncio demanding expla-

nation of the deaths of prelates and others in Sweden. The king accused his unhappy confessor as the cause of the executions. Slaghöck was imprisoned, tortured, and burned at the stake, while the nuncio pronounced the king innocent of all sin. A second legate, however, insisted upon the deposition of Trollé. About the same period two legislative measures, wise in themselves, but which struck at the privileges of the aristocracy, precipitated the fall of Christian. He published a decree which forbade the sale of serfs. A second decree affected property in wrecks: everything cast on shore by the waves had at one time been royal property; but the barons had lately usurped this right, and now it was decreed that the wails should be delivered to the king's bailiffs, to be by them returned to the shipwrecked mariners within the space of one year. Failing this, the property was to be sold, two thirds of the proceeds to go to the king, and the remainder to the church. One year after the sacrifice of Slaghöck, Christian received mysteriously the first announcement of his impending fall. A glove containing a letter from a number of nobles and priests was left in his tent during the night. The king had taken the field against a Lübeck army invading Seeland and Scania. A vast conspiracy of Jutland clergy and nobles was now disclosed to him, and the letter contained their renunciation of allegiance, and announced that they were about to offer the crown to Frederick, duke of Holstein, who accepted the invitation. Christian sent an envoy to the rebellious barons, acknowledging his errors, and praying them to accept again their repentant sovereign. His offers were rejected, and he hurried to Copenhagen, and wandered about the streets, imploring the people to save him from his enemies. Seeland and Scania swore allegiance anew, and Christian might yet have saved his crown. But the weakness which he continued to exhibit cost him every trustworthy friend, and, collecting some 20 ships, he embarked with his family, carrying off the public records, the crown jewels, and all the treasures within his grasp. Sigbrit, who durst no longer show herself, was carried on board secretly in a clothes chest. The king, his wife, children, and a few faithful servants followed, and the fleet sailed from the harbor. This event, which occurred in April, 1523, ended for ever the famous Calmar union, after a period of 126 years. In Denmark the flight of Christian was a serious calamity to the people. His municipal regulations, due to the woman Sigbrit, no doubt were excellent and original. Advocates were admitted to courts to plead the cause of the accused, and to appeal from the tribunals to the crown. He reformed and regulated the customs tariff and taxes. He established inns and post offices for the first time in Denmark. The poor of Denmark deplored the loss of the king who is known in history as a remorseless tyrant. On quitting the harbor of Copenhagen, Christian's fleet

was dispersed by a violent storm. After having been nearly wrecked upon the coast of Norway, he at length reached Antwerp in safety. He found means to invade Holstein with 10,000 men, but was again compelled to flee. In 1531 he sailed again at the head of 12,000 men; his fleet was dispersed, but he landed in Norway, where the new king of Denmark, Frederick, was hated. The Norwegian bishops and nobles declared for Christian, and on Nov. 30, 1531, he was solemnly acknowledged king. The common danger meanwhile brought about peace between Frederick and Gustavus Vasa. A treaty for mutual defence was concluded, and a Swedish army entered Norway. Christian's fate was soon decided. His ships were burned, his troops mutinied from hunger and want, and he was forced to surrender himself to the Danish admiral, stipulating for a safe conduct to Denmark, in order that he might confer personally with his uncle King Frederick. If no amicable compromise of their differences should be arrived at, it was understood that he should be free to quit the kingdom. Frederick was not permitted to ratify the agreement, but was compelled to declare that the admiral had exceeded his powers. So bitter was the hatred of the Danish nobles against their late king, that Frederick was obliged to give them a written assurance that Christian should be kept in perpetual imprisonment. The document containing the pledge was formally committed to the custody of eight barons; and the condemned king entered upon 27 years of retribution. He was first conveyed to the castle of Sonderburg, in the island of Alsens. Here he was placed in a vaulted apartment of which all the windows were walled up, one little aperture near the ceiling alone excepted for air and light, and through which to receive his food. In this dismal dungeon, with a Norwegian dwarf who was given him for a companion, he passed 17 years, the first 12 without any alleviation whatever of his misery. A stone table remains in the castle, around the edge of which is still shown a line of indentation, worn it is said by the hand of Christian, whose sole exercise and pastime in this narrow abode consisted in walking around the table, with his hand resting on it. Still another war was waged for his liberation, but without success. In 1544, at the intercession of the emperor his brother-in-law, the rigors of his imprisonment were somewhat mitigated; and at length, upon the renunciation of all his pretensions in 1549, he was removed to the castle of Kallundborg in Seeland, on the coast of the Great Belt, and made comfortable, with a fixed income, and with permission occasionally to hunt in the adjoining forest. But calamity had worked upon his mind, and attacks of despondency became of frequent occurrence. These were made violent by immoderate use of wine, and at Kallundborg his malady often assumed the charac-

ter of insanity until he died. He had had three children. John, the eldest, was educated under Charles V., but died at Ratisbon on the day his father was imprisoned at Sonderburg. A daughter, Dorothea, was married to the elector palatine, Frederick II.; and Christina first to Francis Sforza, and subsequently to the duke of Lorraine. **II. Christian IV.**, born in the palace of Fredriksborg, April 12, 1577, died in Copenhagen, Feb. 28, 1648. His father, Frederick II., died April 4, 1588. Under the direction of his mother, Sophia of Mecklenburg, and the senatorial council of noblemen, which latter usurped the regency during his minority, he became proficient in foreign languages and mathematics, and especially in naval sciences. After the declaration of his majority as duke in Schleswig-Holstein in 1593, and as king in Denmark and Norway in 1596, and his coronation in the latter year, he applied himself to the promotion of reforms in Norway, which country he had previously visited, and where he subsequently founded Christiania, the capital, and Christiansand. Russia and Sweden claiming sovereignty over the Norwegian portion of North Lapland, Christian made in 1599 a naval demonstration against the former power, and considerably increased his armaments. But peace was not disturbed till 1611, when Charles IX. of Sweden, who had arrogated to himself the title of king of Lapland, and who was jealous of the increasing power of Denmark on the Baltic, attempted to exclude the Danish shipping from the coasts of Livonia and Courland, fortified the town of Gothenburg, and perpetrated other acts of defiance which led Christian to engage in hostilities. He immediately occupied the island of Öland and the citadel of Calmar, whence the name war of Calmar; captured other Swedish strongholds, and destroyed Gothenburg. Gustavus Adolphus, who succeeded to the Swedish throne after the death of Charles IX. in 1611, concluded a treaty of peace with Christian at Siörod in 1613, through the mediation of James I. of England, who had married the princess Anne of Denmark, sister of Christian. By the terms of this treaty the Swedish sovereign relinquished the title of king of Lapland, recognized the freedom of navigation of the Baltic, and paid 1,000,000 rix dollars for regaining the territory taken by Christian, who waived the claims which he had occasionally asserted to the Swedish crown. Christian now devoted himself more than ever before to the arts of peace. He extended and embellished Copenhagen, reorganized the university, increased the number of churches and palaces, established an observatory, a botanical garden, a free school for poor students, gymnasias, and libraries, and founded an academy at Sorö for young noblemen, with eminent foreign professors, to check the practice of studying abroad. Displaying the same energy in promoting commerce and enterprise, he opened

the trade with the East Indies, where the first Danish settlement at Tranquebar was founded by a trading company under his auspices. He stimulated geographical explorations by sending out a number of expeditions for the discovery of a passage between North America and Asia, which paved the way for Norwegian and Danish settlements in Greenland. Among the new towns founded by him was Glückstadt, as capital of Holstein, for the defence of the Elbe, whence arose the name of the Holstein-Glückstadt dynasty, to distinguish it from that of Holstein-Gottorp. As duke of Holstein, and to that extent a sovereign German prince, and owing to his high renown, he was selected in 1625, during the thirty years' war, as chief of the Protestant armies, and personally assumed command in the circle of Lower Saxony. He crossed the Elbe at Stade with 25,000 Danes, Germans, Scotch, and English, and was reinforced by 7,000 troops from the circle. He was defeated, Aug. 27, 1626, by the vastly superior forces of the Bavarian general Tilly at Lutter, near Wolfenbüttel, and was obliged to fall back on Stade, where he was joined by 6,000 British troops and by a small corps of French. But he was forced to retreat before Wallenstein, who had made a junction with Tilly; and the imperialists invaded Holstein and Jutland. The duke Frederick III. of Holstein-Gottorp, Christian's nephew and vassal, betrayed Denmark by making a separate treaty with Wallenstein in 1627, surrendering to him the national fortresses; while the foreign occupation created a spirit of discontent in the duchies, which became a source of disturbance and contention. Supported by Austrian and Spanish forces, Wallenstein occupied the ports of Rostock, Wismar, and other places on the Baltic; but Christian inflicted severe losses on him at Stralsund, and forced him to raise the siege of that city. Peace was finally concluded at Lübeck in May, 1629, Denmark recovering Schleswig-Holstein and Jutland, but, with the exception of these territories, renouncing all interference in German affairs. Her allies, especially the dukes of Mecklenburg, were stripped of all their possessions; and except for the influence of France, Christian himself would have been doomed to great humiliations. Barely recovered from these calamities, but nothing daunted, Christian in 1630 chastised the citizens of Hamburg, who had disputed the Danish supremacy of the Elbe, by destroying 30 of their men-of-war, and imposing upon them the payment of dues for each vessel passing Glückstadt, and at a later period demanding an indemnity of nearly 300,000 rix dollars. The senate, consisting of the nobles, continued in the mean while to thwart the attempts of Christian to protect the national interests on the Baltic against encroachments by foreign powers. Sweden availed herself of this state of things to form a coalition with Holland against Denmark, and Christian made a secret alliance with the emperor Ferdinand III.

against Sweden. At the instigation of the Swedish chancellor Oxenstiern, Holstein was invaded by Swedish forces in 1643, the duke of Holstein-Gottorp once more betraying his liege lord by placing the enemy in full possession of the territory. In a naval action off the island of Femern, near Kiel, known as the battle of Kolberg heath, Christian was severely wounded and lost an eye. His heroism, commemorated in a famous national ballad, greatly enhanced his personal popularity; but the war ended disastrously, chiefly owing to the opposition of the Danish senate to its continuation, and the king was reluctantly obliged to conclude the treaty of peace of Brömsebro (Aug. 13, 1645), ceding the Norwegian districts of Jemtland and Herjedland, the islands of Gothland and Ösel, and other territory to Sweden, including the occupation for 30 years of Halland, and releasing Sweden from the Sound and Belt dues, while these were at once reduced for the Dutch to the rate fixed at a later period for friendly maritime powers. In addition to these disasters, Christian was greatly annoyed by the conduct of the duke of Holstein-Gottorp; these dissensions paving the way for interminable future contests in regard to the interior and exterior relations of the duchies. These reverses preyed at length upon the king; and the premature death of his son Christian, the presumptive heir to the throne, was an additional source of sadness, and accelerated his own death. Of a majestic and noble presence, Christian had endeared himself to his subjects by his love of justice and humanity, by his efforts for intellectual and general improvement, and by his gallantry and indefatigable patriotic labors; and his portrait is still found in the dwellings of the peasants as well as of the higher classes. He was succeeded by his son Frederick III.—His queen, the princess Anne Catharine of Brandenburg, died in 1612; and in 1615 he contracted a morganatic marriage with the daughter of Munk, a Danish nobleman, whom he repudiated in 1630. She had borne him many daughters, who married noblemen and senators. Prominent among them, by her virtues and accomplishments, was LEONORE CHRISTINA, countess of Schleswig-Holstein (born July 10, 1621, died about 1698). She married in 1636 Count Corfitz-Uhlfeld, the son of a Danish high chancellor. He became in 1643 major-domo, but after being suspected of conspiring against the life of the king, and incurring general odium, he left Denmark in disgrace. Intriguing in Sweden against his country, but distrusted, he fled to Flanders, where he continued to conspire against Denmark. He was sentenced to death in contumacy, July 24, 1663. He escaped to Basel, but was accidentally drowned while crossing the Rhine, Feb. 20, 1664. His wife repaired to England, where the government secretly surrendered her to Denmark, and she was imprisoned in Copenhagen more than 20 years. Her memoirs, partly autobiographical,

revealing the injustice practised on her, and her sufferings, translated into English by F. E. Bennett, were published in London in 1873.

III. Christian VII., born Jan. 29, 1749, died March 13, 1808. He was the son of Frederick V. and Louisa, daughter of George II. of England. He succeeded his father Jan. 13, 1766, and soon after married his cousin Caroline Matilda, sister of George III. of England. A year after his marriage he set out to travel abroad, leaving his young wife at home, and visited Holland, Germany, France, and England. In 1769 he returned to Denmark, and found the affairs of his kingdom deranged, the finances low, and commerce failing; but, incapable of attention to business, he abandoned the direction of his government to unworthy favorites. At first he appeared desirous of confiding chiefly in his late father's minister Bernstorff, whom he raised to the dignity of count. A young noble named Holcke at this time, however, enjoyed the greatest share of his confidence, together with a physician, Struensee, who had accompanied him in his travels. The queen, regarding Holcke as her enemy, encouraged Struensee to supplant him in the royal confidence. By his aid the queen succeeded in recovering her husband's favor, and at length procured the banishment from court of Hølk and his equally obnoxious sister. Meantime the queen dowager, stepmother of the king (Juliana Maria, daughter of the duke of Brunswick-Wolfenbüttel), had begun to intrigue in behalf of the interests of her son, the king's half brother; and upon the birth of a crown prince (afterward Frederick VI.) the breach between the queen and her stepmother was hopelessly widened. The king gave daily proof of increasing folly and unworthiness. Bernstorff was dismissed; the council of state, the last surviving check upon the royal authority, was suppressed; and Struensee, possessing a greater ascendancy over the king than any preceding favorite, ruled Denmark with an iron hand. He was ennobled, and empowered to issue his master's verbal orders in writing without the royal signature. Many of his measures were wise and just, but his power was at length exercised imprudently. The nobles were already exasperated by his decrees against their privileges; and a law ordaining the liberty of the press, by which he hoped to gain greater popularity, had a contrary effect, as his enemies thus obtained means of exposing and vilifying his ambitious proceedings. On Jan. 16, 1772, the machinations of the queen dowager were crowned with success. Struensee and the queen were arrested on a warrant forced from the king for a pretended conspiracy, the former beheaded, and the latter sent into exile. (See CAROLINE MATILDA.) The queen dowager now governed the kingdom for many years in the name of the king, whose mind sunk beneath these alarms and agitations. Disease brought on by intemperate indulgences had early undermined his men-

tal health, and his further reign was but nominal. In 1784 his son Frederick, supported by the nobles, succeeded in subverting the power of the queen dowager, and became in fact sole regent of Denmark. In 1807, on the bombardment of Copenhagen by Lord Cathcart, Christian VII. was conveyed to Rendsburg in Holstein, where he died. **IV. Christian VIII.**, nephew of the preceding, born Sept. 18, 1786, died Jan. 20, 1848. He was governor of Norway when the treaty of peace of Kiel, ceding that country to Sweden, was repudiated by the Norwegians (Jan. 28, 1814). Christian came forward as the champion of the national independence, assembled an army of 12,000 men, convened a diet at Eidsvold (April 10, 1814), where a constitution was signed (May 17), and was proclaimed king of Norway under the title of Christian I. (May 29). But, unable to maintain his position against the claims of Sweden, which were supported by the allied powers of Europe, he was compelled to conclude a truce at Moss (Aug. 14), and to relinquish the Norwegian crown (Oct. 10). He now devoted himself to artistic and scientific researches, and in 1832 he was elected president of the Copenhagen academy of fine arts. On the death of Frederick VI. (Dec. 3, 1839), he ascended the Danish throne, and was crowned under the name of Christian VIII. (June 30, 1840). The Danish liberals, who had already yearned for reforms under Frederick VI., now became clamorous and demanded a liberal constitution and the settlement of the Schleswig-Holstein question. The king, although at first reluctant to yield, eventually issued a letter (July 8, 1846) in which he declared Schleswig and part of Holstein indissolubly united with Denmark. The serious complications, however, which arose out of this question, could not be settled by the king, who died shortly before the outbreak of the revolution of February, 1848, and was succeeded on the throne by Frederick VII., who died in 1863, and was succeeded by **CHRISTIAN IX.**, son of Frederick, duke of Schleswig-Holstein-Sonderburg-Glückstadt, born April 8, 1818. The second son of Christian IX. was made king of Greece in 1863 as George I. His daughter Alexandra became in the same year the wife of the prince of Wales. Her sister Dagmar was betrothed to the crown prince of Russia, who died in 1865; and in 1866 she married his brother Alexander, the present crown prince. Another daughter, Thyra, was betrothed in 1873 to Prince Arthur of England.

CHRISTIAN, archbishop of Mentz, born at the beginning of the 12th century, died in 1183. He is chiefly celebrated for his military exploits under Frederick Barbarossa, for whom he opened the way to Italy in 1161. On May 30, 1167, he defeated with a small band of 1,000 Germans a much superior Roman force near Tusculum, and seized Civitā Vecchia. After the coronation of the emperor at Rome, Aug. 1 of the same year, Archbishop Christian's task was to subdue Tuscany and the Romagna.

The town of Pisa, which rebelled against his authority, was deprived by him of all its privileges and put under interdict. At the beginning of 1174 he besieged Ancona by land, while the Venetians blockaded it by sea. Peace was established between the emperor and the pope, Aug. 1, 1177; but the archbishop, carried away by his desire to subdue the only party which still held out against the emperor, and which had its headquarters at Viterbo, continued the war, and finally fell into the hands of the leader of that party, Conrad of Montferrat, who detained the warlike prelate in the prisons of Acquapendente till 1181, when he was ransomed. Hardly had he recovered his liberty when he again took up the sword, and fell in battle endeavoring to rescue Pope Lucius III. from the attacks of hostile Roman armies.

CHRISTIANIA. I. A province of Norway, bounded E. by Sweden, and S. by the Skager Rack; area, 11,000 sq. m.; pop. about 500,000. It is covered with mountains, contains the Mjösen, Fämund, Tyri, and other lakes, and is traversed by the Drammen, Glommen, and numerous other rivers. Limited quantities of cereals are produced in the small valleys, and cattle and horses abound. The mineral productions include iron, copper, and silver. The principal article of trade is timber. The province was formerly known as Aggerhuus, the present designation of a district. **II. A** seaport of Norway, capital of the province and of the kingdom, situated at the head of a fiord, in lat. 59° 55' 20" N., lon. 10° 44' 45" E., 250 m. W. N. W. of Stockholm; pop. in 1870, 66,657. The fiord of Christiania, an arm of the Skager Rack, extends inland about 75 m. The streets are broad, the houses chiefly of brick stuccoed. The new palace, Oscar's hall, occupying a fine site a short distance beyond the city limits, was completed during the reign of the late king Charles XV. The university was founded in 1811; the number of students is between 700 and 800; the library contained in 1871 more than 150,000 volumes; and there are belonging to the institution museums of mineralogy, zoölogy, northern antiquities, and botany, and an observatory. There are high schools, a school of drawing for workmen, and a normal school for teachers; several learned societies; commercial, naval, and military schools; an art union, and gallery of paintings of native artists; a national gallery with several treasures of art, and a theatre. Among the principal public buildings are a cathedral, four churches, a council house, exchange, military hospital, and two orphan asylums. The new lunatic asylum occupies a large building, and is arranged on the best modern principles. Among the charitable institutions is one for vagrant and homeless girls called the Eugenia institute. At the southern extremity of the town, occupying a slight elevation, and commanding the harbor, is the ancient castle of Aggerhuus, in which are preserved the national archives and regalia. The ramparts which formerly surrounded the town

have been converted since the peace of 1815 into public promenades and gardens. The prosperity of Christiania dates from the peace of 1814, since which time its population has more than quadrupled. A railway from Christiania to Lake Mjösen, bringing some of the most populous and productive parts of the interior into direct intercourse with the sea, has been in operation since 1849, and an electric telegraph communication with London since June, 1855. The manufactures are inconsiderable, consisting mainly of hardware, glass, woollens, cotton, cordage, tobacco, and corks. The exports in 1871 amounted to \$2,608,442, of which lumber, oats, and cotton yarn were the principal articles. The imports were \$96,460,293, of which cotton, rye and barley, coffee, woollen goods, sugar, coal, pork, and tobacco were the principal articles. The entries into the port were 264 steamers, of 86,732 tons, and 1,330 sailing vessels, of 176,121 tons.—The nu-

The New Storthing House.

cleus of Christiania was the ancient town of Opslo, east of the present city, founded in the 11th century. In the beginning of the 14th century the fortress of Aggerhuus, the first building within what is now the city proper, was erected. In 1523, and again in 1567, Opslo was burned by the Swedes. It was again burned in 1624, when King Christian IV. founded a town around the fortress of Aggerhuus, to which the inhabitants of Opslo soon removed. A wall with bastions was afterward built. In 1630, and again in 1654, half of the inhabitants died of the plague. The great London fire of 1666 laid the foundations of the trade of Christiania, by creating a demand for Norwegian lumber. In 1716 the Swedes took possession of the city, but were driven out in six weeks, after which the fortress was much strengthened. In 1858 a fire took place in which 60 buildings in the centre of the town were burned, and 1,000 people rendered house-

less, the loss being estimated at \$1,100,000. Since that time a great improvement has taken place in the architecture of the dwellings, many of which are of large dimensions. The *Christiania Intelligentsedler*, founded in 1763, is the oldest Norwegian newspaper.

CHRISTIANITY, that system of religion of which Christ is the founder. What was accomplished by his Spirit through the apostles and others is to be referred to him no less than that which was performed by his own direct agency. Viewed in the light of its immediate cause, it was the infinite love of God, embodying itself in Christ and working out redemption for men. Considered as an act making provision for the restoration of men, it was the manifestation of a divine and perfect being in human flesh, a condescension to our condition in order to exhibit a life of sinless perfection and of complete self-sacrifice, as the means of liberating from the power and curse of sin all

who should willingly enter into his spirit and adopt his principles of action. In its essential nature, it is neither a system of doctrines, nor a collection of historical facts, nor a code of morals, nor a body of religious observances. It is all this and much more. It is a new-born heavenly life, emanating from Christ, conformed to his example and to all truth, embracing all virtue, intimately blended with nature and history, and manifesting itself in acts of homage to God and of love to men. The germ of all its positive principles was con-

tained in the person, character, and life of Christ. The complete development of this, and its application to all the relations of life, would constitute practical Christianity as it was designed to be, and as it will be when it shall be conformed to its ideal standard. Christianity in such a sense reveals itself in every phase of humanity, whether individual or social. It reaches further and comprehends more than the church. The latter does not embrace the state, but is rather its counterpart. The church and the state represent two aspects of human life, the religious and the secular. Christianity relates equally to both. The state is to be Christian, but not ecclesiastical. Philosophy, science, literature, art, business, private and social life, are all to be Christian, but surely not ecclesiastical. Indeed, if the individual is to be like Christ, inwardly as well as outwardly; if in him a divine principle is to pervade all that is human; if by the grace

of God Divinity and humanity are to be in contact with each other in him, it cannot be otherwise than that Christianity shall extend equally to everything in human life. Every day is, in a certain sense, a holy day, and every act is a Christian act. Such will be the kingdom of God, such Christianity in its complete triumph. But while the church and the state are to be equally Christian, the promotion of Christianity is to be the direct aim of the one, while it is to be only the indirect aim of the other. The activity of the church therefore, being more directly religious and exerted only under religious forms, is often very naturally supposed to be a complete and adequate representation of Christianity. It is owing to this that many writers have erroneously, we think, considered Christianity and the church as identical. Christianity in a subjective sense is the inward life of the individual, answering to the provisions of the gospel made for him and existing out of him. It is a personal, free act of appropriation made under spiritual influence, by which Christ is received, in his entire character and spirit, in his offices, and in his work, as our redeemer, teacher, and example, and, in short, as our life. This act involves the renunciation and abandonment of whatever is opposed to the spirit of Christ, and a heartfelt sorrow for all previous participation in it, which is the negative side of Christianity; and on the other hand, confidence in God as a loving and merciful Father, and trust in Christ as the medium of God's redeeming love to men, which is the positive side. Supreme love to God is the radical principle of Christianity, as the religion of the heart; and love to men, not only as a sentiment, but as a practical energy expending itself in self-denying and self-sacrificing efforts for their good, in the spirit and after the example of Christ, is the necessary and invariable product of that principle. Hence, in the matter of personal religion, he who is without love is nothing. This inward spiritual life received from Christ may not be perfectly realized and wholly conformed to his at any given moment of our present existence; but it is received in its seminal principles as soon as Christ is received, and the development will go on till it reaches perfection in the world to come. The progress of the individual in this divine life is in proportion to the will and the effort which he gives to it. While on the one hand his Christianity is a gift and a grace, on the other it is a culture and a work. The believer in Christ is not a passive recipient of his grace, but a voluntary, resolute, strenuous agent, a determined, moral hero, who overcomes difficulties and obstacles because he purposed and endeavored to overcome them. Christ helps his disciples when they help themselves, and lives in them when they strive to live in him.—As Christianity is founded on Christ, it will be necessary to delineate those peculiar features of his character which are most essential to it. The one fact on which all

other things in the redemption of mankind depend is that of "God manifest in the flesh." That God was in Christ, and was represented by him, is a fundamental principle in the Christian system, as explained by Christ himself and by his apostles. The incarnation laid the foundation for human redemption. There was thus a second Adam, a new head of the human race—the true man, having a divine lineage, and the Spirit of God without measure, bearing his image and doing all his will, acting in every moment of life with a perfect spontaneousness and freedom, leading a life at once divine and human, avoiding sin and thus passing sentence against it, taking upon him its outward consequences by putting himself in fellowship with the sufferings of sinful men, and in this state of voluntary humiliation and suffering revealing the infinite condescension and love of God to his erring and unhappy offspring. In all this act of redeeming mercy is to be seen the true type of practical Christianity: a holiness that is separate from sin and condemnatory of it; a humility that is unambitious and unpretending, seeking merit and not rank; and a love that seeks not its own, but sacrifices all external things for the good of others. The mystery of redemption by Christ we may not be able to explain; but that a whole embryo Christianity lies concealed in the wonderful life and death of the incarnate Son of God is too evident to admit of doubt. It is the taking of human beings up into fellowship with his human nature, as well as his descending to them by entering their nature, and holding communion with their sufferings, that opens the way for God to dwell in men, and for men to dwell in God. The divine and the human were first harmonized and reconciled in the person of Christ, and from him as a nucleus spreads out, by means of his Spirit, a broader harmony and reconciliation between God and all his children. Such love and such a sacrifice on the one part, and such a reception of Christ and of his divine life on the other, render the method of redemption consistent both with the divine government and with the moral constitution of man. The righteousness of Christ, which is accepted of God, is also accepted on the part of man, as the germ of a new life. In this way every end of a wise government is secured, and man is restored first to the image and then to the peculiar friendship of God. There is one feature of this system that needs to be more fully set forth. It is that view of Christ which presents him as the ideal of humanity. The want of such an ideal of human perfection was deeply felt by the ancient world. To the question, What precisely should men strive to be? no satisfactory reply could be given. Men were far from being agreed in respect to "the chief good;" and in the various theories maintained there was necessarily much vagueness, as nothing but abstract ideas could be presented, a living

model of moral perfection being neither actual nor possible. Even if there could have been a perfect agreement about an ideal existing only in thought, it would have had but little power upon the common mind. It could not have been sufficiently definite and clear for practical purposes. What, therefore, was necessary to constitute a perfect man no one could positively affirm. Certainly, there was in all the speculations of the philosophers no approach to the Christian idea of what man should be. There was in this circumstance a sort of necessity that the idea should be embodied in an individual person of the human species; otherwise it could never be fixed definitely in the general mind as the end of all its practical aims. Had Christianity done nothing more than to exhibit such a human character as that of Christ, still in presenting to the comprehension of all that living image of what human nature should be, it would have accomplished more in the way of teaching virtue than all the other moral systems of the world. All that can be done by the power of an idea has been done by the mere existence of such a person as Christ. The moral character of all Christian nations is precisely what their various attempts to attain to the excellence of this model have made it. No individual has equalled the normal type of humanity; nor has the whole school of his disciples collectively attained to the virtues of its founder. What other example is there in the history of mankind where the single founder of a school has been able to hold such a preëminence over the collective attainments of all his various disciples for successive ages? If human nature was designed, not for a separate and independent existence, but for an existence in most intimate connection with Divinity; if it was to be enlightened, guided, influenced, and moulded by the latter, by having a vital and uninterrupted spiritual union with it, and finding its true destination and well-being only in that state, a life not only from God, but in God, then there is nothing that exemplifies all this in such absolute perfection as the life of Jesus. Here we behold "the Model Man" in his union with God—"I in them, and thou in me." If Christ, besides all his other redeeming acts, has in his life as a man exhibited the just relations between humanity and Divinity by keeping them always in union and harmony, he has made this grand, this most marvellous exhibition for the benefit of human nature at large; and having been accomplished once, it needs not to be repeated. In respect to the fitting time or place for such an exhibition, it may not be becoming for mortals to attempt to judge. But, as we have the divine method before us, it is neither irreverent nor presumptuous to search for the evidences of its wisdom. If it is an event to occur but once, it would seem natural that it should take place in some focal point of the world's history. That it should succeed a

period of the highest pagan culture, so as to show what mere human culture could not do, and should make its appearance in a nation the most favored in respect to religious knowledge, so that the heavenly plant might be put into a prepared soil, the most perfect revelation of God be made to those who already knew most of God, would seem to be both reasonable and appropriate. In this way, it would take up the great problem of the destination of human nature and of human society in that stage of its solution where the world under the most favorable circumstances, as it respects both pagans and Jews, had left it. No doubt, as the western borders of Asia, where the three tides of Asiatic, African, and European civilization met, presented a suitable theatre for the introduction of Christianity, so the period that closed ancient history, and opened the way for a new and very different history in ages to come, may be supposed to enter largely into that assemblage of circumstances which marked the "fulness of time." The greatness of the Christian religion consists in the energy with which it actually impresses that type of character found in Christ upon a great mass of human beings of different countries, and in different ages of the world. This is its greatest peculiarity, viewed as a practical system. Here it stands confessedly alone. Such a power it could not exert unless there was a reality both in Christ's character and in its causal relation to ours. He must have had a divine life in himself, and have been the source of a similar life in his followers. Other founders of religious systems are teachers, authors of institutions, of organizations; or, under mythical forms, they present symbols of what is supposed to be divine. Not one of them, as a historical personage, holds the relation of a vital source, or even of a prototype of all that he expects or desires to see produced in others. Even what Moses was in himself was not a matter of vital importance; little comparatively depended on that. He was not in his own person the standard of what he taught; much less was his spirit the source of religion. Like other good men, he pointed to something higher and better than himself. But Christ was himself all that he wished his disciples to be; and the reproduction of himself in them individually by a spiritual energy was the chief aim of his religion, and his success in this undertaking is its chief glory.—From this conception of Christianity, and of its founder, which may be regarded as a theoretical view, let us advance to a historical estimate of the exalted character of Christ. In what light did he view himself, and in what attitude did he present himself to the world? As the exalted personage in whom were fulfilled all the predictions of the ancient prophets in respect to the Messiah, and in whom was realized in a substantial and perfect form all that was shadowed forth in the types of the Jewish ritual and law. He regarded himself as the

great deliverer of his nation, toward whom all previous history had pointed. For the whole generation of men to whom he appeared he professed to be more important than any or all others. Their moral character was to be tested, and their final state decided, by the reception or rejection of himself as their spiritual guide and Saviour. Nay, more, for all men, and to the end of the world, this preëminence both in a historical and moral point of view was to remain the same. He claimed, in short, to be the one individual on whom the well-being of all men depended. This is certainly a unique position to be assumed by any individual of the human race. If true, there is nothing in history that approaches it in sublimity and importance. How many correspondences does this suppose between himself and a broad sweep of historical events stretching from age to age! If such is his real character, it must be the key to the whole moral and religious history of mankind. Every new century must, with its train of coincidences, confirm the marvellous view. That he actually entertained such a view of himself does not admit of a doubt. The whole history of the apostolic age would be an enigma on any other supposition. The Jews often accused him of it during his public ministry. The general idea, under a great variety of forms, is exhibited by Christ in his public discourses, as reported by the evangelists. The whole structure and argument of most of the epistles presuppose it. The primitive church itself was organized on this as a fundamental principle. What, now, was the effect produced upon society by the appearance of Christ as such a historical character? The first thing which arrests our attention is the stupendous power which he exerted upon the minds of all classes of people with whom he came in contact. With whatever feelings his enemies approached him, they always stood in awe and often in fear of him, after having encountered him. After many attempts by means of argument to strip him of his influence with the people, they clearly saw that nothing but physical force could overcome him. They crucified him because it was not safe for them that he should live. What mortal ever addressed the people with such convincing power as he? We admire the teachings of Socrates as represented by Plato; but what are they compared to the conversations and discourses of Christ as reported by John? We may think that Socrates owes somewhat of his celebrity to the splendor of Plato's genius. We will not deny that it was well that there was such a disciple as John, one so happily fitted to receive and record the peculiar spirit of Christ's teachings. But to suppose that Christ is indebted to John for the loftiness, purity, and simple majesty of his instructions, is only to transfer the marvellous power to another person. It would only make John superior to Christ, which would be not only more unhistorical, but more enigmatical in all

respects than the contrary view. Still more striking was the moral influence of Jesus upon the men whose distinctive character as Christians was formed by him. What were Peter, John, and Paul, as he found them? And what were they as he left them? Think of the rough and dashing Peter as first seen on the sea of Galilee. How subdued and chastened, when the risen Lord said to him, "Feed my sheep." With what power and wisdom does he stand up before the multitude on the day of Pentecost! With what moral elevation, dignity, and completeness of character does he appear at the healing of the lame man at the entrance of the temple! With what respect, veneration, and awe must he have been regarded at the scene of the death of Ananias and Sapphira! Who can read his first epistle, addressed to the dispersed of Israel, without feeling that the touching power of his eloquence came from a soul that had received something beyond what the ordinary experience of life had given it? The transformation of his character is certainly surprisingly great. In tracing the change wrought in the character of John, we have similar evidence of the operation of a superhuman power. At the beginning he is a fiery, ambitious youth, calling for vengeance upon those who teach differently from his Master, and seeking for a position of rank and honor in Christ's future kingdom. After his long and peculiar intimacy with Jesus, how strangely does he appear to be changed into the same image. Was it not the Spirit of his Lord and Master that changed him? Would his natural genius, without any extraordinary influence, have enabled him to write such an angelic gospel as that which bears his name? Who but Jesus of Nazareth made of the misguided, frantic, persecuting Saul the most splendid human character, perhaps, that adorns the history of mankind? Before his conversion it cannot be said that he had such a moral preëminence above other men. Without such a conversion, without the influence of Christianity, though he might have been a man of great natural power, there is no reason to suppose that he would have approached that character which the new religion gave him, and which made him the moral hero of his age. We may safely challenge all the heathen world to present two such men as John and Paul, or a single book of such moral sublimity and beauty as the gospel of the former, or any writings of such religious depth, compass, and power as the epistles of the latter. We have selected these single individuals for the sake of giving a microscopic view, as it were, of the spiritual power of Jesus over the minds and characters of men. If our space allowed us to extend the examination to hundreds and thousands of other individuals, we should find in them as genuine, if not as brilliant, specimens of high moral excellence produced by the power of Christ. What communities ever presented such a spectacle of sublime moral ac-

tion and endurance as the primitive apostolic churches? All the Christian heroes that have lighted up the darker history of many centuries have only renewed the martyr spirit which was exhibited first by Christ on the cross, and then by countless other bleeding victims nobly offered up to God in the golden age of the church. These are only a few of many facts which have a veritable and incontestable place in history, and there is no other satisfactory explanation of them than that of referring them to the mysterious power which Christ exerts upon the minds of men.—If it be objected that the facts on which we rely in construing Christianity are themselves dependent on the authority of the New Testament as an inspired volume, and that this is an undue assumption in a historical argument, we say in reply that we make no such assumption. We take the New Testament writings in this case for just what they are found to be worth as historical documents. Waiving all discussion in respect to their inspiration, we have good reason to say that the epistles of Paul, the writings of Luke, and the Gospel of John have passed the ordeal of the severest historical criticism, and that Strauss himself, the most destructive of all the Biblical critics, while he fluctuates in regard to the last, admits substantially the historical authority of the two former. Let the writings of these three authors be tried by the same rules as those applied to other historical documents, and we think the credibility of their main facts will be called in question by no well informed and sober-minded critic. Their inspiration is not their only title to being received as historical authority. Even occasional errors and discrepancies would not necessarily destroy their authority, any more than those found in Plato and Xenophon destroy the credibility of these writers in their accounts of Socrates. If it be conceded, as it generally is, that the New Testament writings above named, whether inspired or not, are in the main genuine sources of historical information, then the view which we present of Christianity is a strictly historical view, and has a place in the history of the world as much as the expeditions of Hannibal or Alexander.—With this explanation, we proceed. In respect to the method which Christ pursued in beginning the work of the conversion of mankind, we observe something like the following. On entering upon his public ministry, his first aim was to impart his own temper and spirit to a few others, scattering at the same time the seeds of truth among the people. He began by effecting what others before him had failed to do, improving the human heart, and allying it to himself in the bonds of holy affection. His instructions and his acts were means to this end. Among John's disciples, plain and simple-hearted fishermen, he found those who were most susceptible of pure spiritual ideas and spiritual impressions. By gradually forming their hearts to true piety and

virtue, by unfolding to them the nature of his spiritual kingdom, by removing their ignorance, by correcting their misapprehensions, by overcoming their prejudices, by elevating them into his own region of moral purity, simplicity, and truth, by training them to meekness and humility, and at the same time to the most exalted moral heroism, to a supreme regard to the will of their heavenly Father, and to an unlimited confidence in him and contempt of the world, the Divine Teacher moulded the character of his disciples till it resembled his own, and prepared them to propagate the same spirit and principles in all the world. The apostolic office was not arbitrarily conferred, but was given to those who had been sedulously trained for it. His public ministry was as remarkable in its character as was his private training of the twelve. While he was chiefly concerned with the profoundest truths, and the most comprehensive and far-reaching principles, his manner of teaching was imitatively natural and simple, growing out of the incidents and occurrences of life, or called forth by questions arising from them. Whether the matter was more sublime and weighty, or the manner more easy and simple, it were difficult to say. And yet most of his teaching was preparatory to something more complete which was to follow. Prejudices and errors which hung like a cloud upon the mind were broken in upon by degrees, as the darkness of night is by the approaching morning. Important moral truths were stated in their most elementary principles in a living, natural, concrete form. Unwelcome truths, relative to his own future authority and greatness, were more or less veiled in temporary obscurity, till events should set them in a clear light. Facts not yet known, or events near at hand, if they would too much startle the mind and prematurely excite the murderous hostility of men, were hinted at enigmatically in public and then more fully explained to the disciples privately, to be made public only when the proper time should arrive. The crucifixion and the resurrection would make all these things plain. Till then, no small part of Christ's teaching was necessarily obscure. His particular aim evidently was not merely to convert individual men, but more especially to prepare the public mind for the days of Pentecost and for what followed. Never was a plan more evident than that observable in Christ's ministry as introductory to the ministry of the apostles. His teachings were morally the leaven of the succeeding age, pervading the whole mass of society.—Let us now take our stand among the disciples on the day of Pentecost. The image of him whose glory they saw as that of the only begotten Son of God, full of grace and truth, was still fresh in their minds. His miracles, such signal manifestations of divine power and love, had not faded from their vision. His remarkable discourses, as repeated by John, which made the multitude exclaim, "Never man spake like this man," were treasured up as a

precious legacy in their hearts. The scene of the transfiguration, with its obscure symbolical import, had not passed from their memories. His dark sayings, enigmatically expressed before the multitude, but confidentially explained to the disciples, respecting his decease and the glory that should follow his resurrection, were receiving a complete elucidation by a series of the most astonishing facts. Why were the dejected and dispersed disciples now assembled together, buoyant with hope, and burning with fresh zeal? Had not something occurred to produce this change? Could the scene of the Pentecost have opened if the resurrection had not intervened between that and the crucifixion? Could the men, whose worldly fortunes and lives were hazarded by the assertion, have believed and have persuaded even the Jews of Jerusalem to believe that Christ was risen, if nothing, absolutely nothing had been seen or known of him after his public execution? Christ had foretold his death and resurrection. The disciples had seen him repeatedly after his resurrection. He had promised the effusion of the Holy Spirit. They had assembled and waited and prayed for it. The promise was fulfilled. The fulfilment was of the most remarkable kind. Its effects were of the most public nature. The train of circumstances was such, the evidences were so overwhelming, that even those who crucified him were convinced, and added to the disciples. Such events, so remarkable, so undeniable, so public, in the very place where opposition must have had a perfect triumph, and the credit of the disciples must have been completely ruined, by the demonstration of the untruthfulness of their testimony, if Christ had not risen, were a fit preparation for the grand inauguration of Christianity as the religion of all mankind. We do not know exactly what that baptism of the Holy Ghost was, those peculiar operations of the Spirit, those diversities of gifts. But we do know that the expectations of the disciples to whom the promise had been made were more than realized; that their faith was so confirmed as to give them great boldness and to put all their previous doubts to flight; that during the lifetime of their Master they had never had such confidence in their cause, or such courage in maintaining it; and that this enthusiastic ardor did not pass away as a transient day dream, but became the effective and enduring cause of the rapid spread of the new doctrines and of the manifestation of the rarest and most exalted virtues which for three centuries irradiated the world in the midst of the most appalling scenes of persecution. There is no other satisfactory explanation than the one above intimated of the spread of Christianity under the ministry of the apostles, dating from such a time as the period immediately following the crucifixion, and beginning at such a place as the very scene of the crucifixion, among those who were witnesses to it. The vigor of Christianity, as shown then and in all succeeding ages, its power as the

great civilizer of the world, its vitality, which throws off the corruptions of centuries, and perpetually renews itself, its exalted character as the precursor of the mightiest achievements of the human intellect, its unrivalled potency in producing a sterling and substantial morality, its power to solace human griefs, all demand an origin more substantial than myths and sagas, more vital than the dreams of an enthusiast, or the superstitions of an ignorant, credulous populace. The early propagation of Christianity rested preëminently upon an extended group of the most astonishing, and yet the most incontrovertible facts. If the essential facts are not true, the doctrines founded upon them are not true; and both these being abandoned, the splendid fabric of a historical Christianity, the most potent moral agency in the world, remains without an explanation. It would seem that, in an age so imbedded in false views of morals and religion, with a literature, philosophy, art, and government so alienated from the truth, and a life so given over to sensuality and gross immorality, there was need that a nascent Christianity should have a fresh, vital beginning; that, wanting a history and the demonstration of its moral tendencies from the trial of centuries, and all that accumulation of evidence which time has now given, it should be ushered in with a special divine energy, and be advanced by means of extraordinary gifts and aids. Gushing thus as from an overflowing fountain, the stream, which is now spread out into an expanded even volume, might, in its narrower compass, form a deep boiling current, as if rushing from a mighty cataract. As with the individual the first stage of a religious life may be accompanied with feelings intensely fervid, and with an enthusiasm and zeal which are then necessary to surmount great discouragements and obstacles, so Christianity as a whole might properly have a concentration and intensity of power at the outset, for which the far wider though gentler influences of later ages are a sufficient compensation. If the primitive Christians had some aids and evidences which we have not, we have very many which they had not. It was not, however, merely the extraordinary gifts of the apostles and the extraordinary events connected with their ministry that caused the dissemination of the Christian faith. What arrested equal attention and produced equal effect was the character of the professors of the new religion. The purity of their lives, their strict integrity, their firm adherence to the loftiest principles of morality, their disregard of consequences when urged to violate their consciences or their religious vows, their patience under injuries, their forgiving spirit, their magnanimity, their love to each other and even to their enemies, and their benevolent, self-renouncing, and self-denying spirit, made it impossible for the ingenuous among the heathen to withhold their admiration. The Christian life, in contrast with heathenism, was one standing miracle. Christian-

ity itself contained nothing more wonderful or more convincing to its adversaries than the Christ-like spirit of its adherents. Though they were all imperfect, and though some of them fell into errors and into sins, yet we learn not only from the apostolic writings, but from the testimony of pagans, that their attachment to truth, and to the purest principles of morality, and to all the virtues of a truly Christian walk, was such as to present the most striking contrast to what was observed among other people. Connected with this devotion of spirit was the earnestness with which every disciple espoused the Christian cause. Every one was a propagandist. That religion which was all things to them, they wished to communicate to others. They saw men living without God in the world. The same compassion which moved Christ to devote his life to the salvation of men, prompted his followers to render that salvation as availing to all their fellow men as possible. Wherever a Christian went, Christ was preached, and the faith was propagated. A Christian captive was sometimes the means of converting whole communities and nations. The spirit of its founder animated the church, and conversions from idolatry were rapidly multiplied. The age of Christ and of his apostles is the turning point in the world's history. There is no other epoch of equal importance in itself or of equal influence upon mankind. If we ask what has made the moral history of the world gradually improve from that date, no cause so powerful can be named as Christianity. As the industry of man has given a new face to nature, so the spirit of Jesus Christ has given a new aspect to human society. Its influence is so all-pervading that it is difficult to specify particulars. It new-models the individual morally, and elevates him intellectually. It acts upon the family in modifying and ennobling all its relations. The wife and mother is exalted to a nobler sphere, and her position of newly acquired honor enables her to shed a most benign influence upon the family and upon society. The husband and father is a priest in his household, and has more sacred feelings of humanity and tenderness to those whose happiness and fortunes are placed at his disposal. The child, first secured against infanticide, then elevated as a moral being, and educated to Christian virtue, makes the love and respect of parents a part of his religion. And so the whole domestic relation is improved and sanctified by the example and teachings of Jesus. The exaltation of nature which blesses the individual and the family reaches also the state, and teaches it to respect the rights and to seek the well-being of the individual. It no longer makes itself the end and men the means, as in ancient pagan times, but is itself a minister to man as a social being. It recognizes the rights of other nations, regards itself as an instrument for promoting the interests of mankind, and acknowledges a higher aim than its own selfish purposes. Though the state is the last to feel the direct power of

Christianity, it is beginning to consider itself commissioned by the genius of Christianity to do something noble as well as just for the whole brotherhood of man.—It remains for us to sketch the working of Christianity from the time of its establishment to the present. This is not the place to give the details of ecclesiastical history; and yet the influence of Christianity upon the world cannot be portrayed without involving what is most spiritual and vital in the history of the church. It will be convenient to divide the Christian age into three periods: the early period, when the church was oppressed and persecuted, reaching to the time of Constantine; the mediæval period, when the church was recognized as catholic, and was for the most part dominant; and the Protestant period, during which Christendom has been divided into two great parties, and the authority of the church over the state has been greatly diminished. Though the second period has a duration about four times as great as either of the others, in their relative historical importance they stand nearly on a level with each other.—*First period, extending to the year 311.* At the time the apostles were zealously propagating the faith, the age of classic antiquity was nearly gone by. Neither Greece with its individuality, liberty, and intelligence, nor Rome with its stern rule and power of conquest, had furnished anything which could perpetuate social progress and preserve nations from decay. Unless a more potent conservative element could be thrown into society, the prospect was that all nations would share the fate of the great monarchies of the East, every period of great civilization being followed by a relapse into barbarism. Judaism, which was never designed to be universal or perpetual, had done its work, and was already effete. It was easy to see, within a very short time, that if there were any regenerative power which could arrest the tendency to decay, it must be found in the inspiring youthful enthusiasm of the new religion. Instead of the prevailing skepticism, the Christian had a positive faith. Instead of limiting his views to a mere earthly existence, and living after none but selfish principles, he lived for another world, and after another's will. His character and life were hereby ennobled. He knew the worth of the human soul, and would not violate its obligations nor jeopard its interests to please men. He had the loftiest style of character, and was capable of the highest and most difficult virtues. Herein lay the vigor of the Christian cause; and the want of all these things made the whole fabric of the Roman empire but a hollow shell. Hence, in the protracted struggle of three centuries between paganism and Christianity, the one was continually sinking while the other was steadily rising. The class of men of whose existence in any political relations Trajan needed to be informed, gave character to the whole empire under Constantine. Within a third of a century after the death of

all the apostles except John, that is, at the close of the 1st century, Christians were found in nearly all the countries bordering on the Mediterranean sea, especially in Asia Minor, Greece, Italy, and the north of Africa. In the next two centuries not only did churches become numerous in all these countries, but they sprang up, here and there, in nearly all the other provinces of the empire. During this whole period Christianity was opposed, sometimes by unrestrained popular violence, sometimes by the government, and sometimes by men of learning. After the destruction of Jerusalem, Christians being no longer confounded with the Jews by the emperors, and their numbers being now mainly increased by converts from paganism, persecutions were directed against them as Christians. Under Domitian, Christians were punished as traitors. Trajan moderated persecution; Hadrian and Antoninus Pius required that it should be conducted under forms of law; Marcus Aurelius gave a loose rein to the popular fury. Then ensued a period of 70 or 80 years, during which the emperors manifested little interest in the subject, and individual magistrates were left to follow their own inclinations. So much the more severe was the persecution of Decius, the first that extended throughout the empire, to the Christians who had become accustomed to a comparatively easy and tranquil life. After 50 years of interrupted or mitigated persecution followed the second general persecution under Diocletian, which ended with the change of the empire from a pagan to a Christian state. While many men of literary eminence appear to have used their influence against Christianity, Celsus and Porphyry, the former near the middle of the 2d, and the latter toward the end of the 3d century, are the chief antagonists who appeared as authors. The Christian apologists, Justin Martyr, Tatian, Athenagoras, Tertullian, and Origen, put an end to the false and puerile accusations brought against the Christians, and led to this result, that the great question between the two parties now struggling for existence henceforth turned on its real merits. In this period, a distinction appears between the clergy and the laity, as also between presbyter, bishop, and metropolitan; the sees of Rome, Alexandria, and Antioch hold a preëminence above others, and provincial synods are held. The writers of the church directed their attention chiefly to what were denominated heresies. Among these, the various forms of Gnosticism were prominent. Other questions which began to agitate the church were amply discussed in the next succeeding period. The authorities relied on were Scripture and tradition. A lower tone of morality, both in the clergy and in the laity, had in too many instances begun to prevail.—*Second period, from the time of Constantine to that of Luther.* There are three things of most extensive influence that mark this period: the new world of thought opened to the specu-

lations of an undisciplined age, the new attitude of Christianity as the religion of the court and of the state, and the new character of the population of the empire, introduced by the invading armies of the barbarians. These three circumstances enter largely into the causes which gave to the middle ages their peculiar character and condition. The first had operated before. But as the former period was chiefly of a practical character, with but here and there a speculative mind in the first two centuries, and with undeveloped tendencies rather than completed results in the 3d century, there will be more unity in the treatment of the subject by viewing the whole movement together. Nothing ever so extended the field of human thought, or so aroused the capacities of the mind, as the revelation of Christian truth. It came at a time when almost all systems of philosophy were broken down, when men despaired of ever arriving at certain truth, when the age of profound thought had gone by, and everything tended to intellectual weakness, to decay, and finally to gross barbarism. Still, in such untoward circumstances, it gave an astonishing impulse to the human mind. What are all the stupendous systems of Gnosticism but attempts of minds still pagan in a greater or less degree to strike out theories of the universe that should comprehend the mediation between the finite and the infinite, after the idea contained in the incarnation of the Son of God? The new Platonic philosophy itself might never have been developed in Alexandria had not Christianity rendered a new philosophy absolutely necessary. On minds essentially sound and Christian, we see the new scope which Christianity gave to thought in Justin Martyr, Tertullian, Clement, Origen, and Augustine. If it be the province of Christianity, not only to overcome all absolute evil, whether as opposed to truth or to the right, but to bring out and cure all partial evil where error has with it some admixture of truth, and wrong associates with itself some things that are right, we shall not be surprised that in the beginning, when Christian philosophy was as much in its infancy as Grecian philosophy was in the days of Thales and Pythagoras, there were ten heresies for every truth, and that the church was like a shrub from which shoot out bristling thorns at almost every point. We have not space even to name every shade of heresy recorded in the annals of the early church. To say nothing of the Cerinthians, Carpocratians, Valentinians, Ophites, Patripassians, Artemonians, Montanists, Manichæans, Noëtians, &c., of the former period, we have a host of parties more or less connected with the Arian controversy, not only the Arians and semi-Arians, but the Eunomians, Aëtians, Apollinarists, Adoptians, Nestorians, Eutychians, Monophysites, Monothelites, and many others. In the midst of these controversies broke out the Pelagian and semi-Pelagian heresies, as they are

called. Constituted as the human mind is, it would be impossible that two such points as that of the Son of God dwelling in human flesh, and that of the Spirit or grace of God dwelling in the human mind, should not lead to much speculation and discussion in respect to the mode of the union. The scholastic theologians added little on these points to the doctrines taught by Athanasius and Augustine. Indeed, it was their office not so much to discover truth as to confirm the decisions of the church. What most characterized the scholastic age in respect to doctrines was the standing controversy with speculative mystics on the one hand, and numerous sects of separatists on the other. There was scarcely a time when both of these tendencies were not ably represented. When Christianity became the acknowledged religion of the state, the whole outward condition of the church was changed. Politics and religion were henceforth combined. Sometimes the state ruled the church, and sometimes the church ruled the state; but never were both kept strictly within their own bounds. We have only to look into the laws of the Christian emperors and the acts of the bishops to find abundant evidence on this point. At the beginning of this period the imperial court at Constantinople exercised a most decisive influence over the church. Not only were high ecclesiastics often dependent on the emperor, and subject to his will, but even councils were awed by his presence. At a later period, and in the West, the head of the church exercised authority over all Christian states. From the nature of the case, where there is such a union of the civil and ecclesiastical power, the one or the other must rule. There must be a last resort in all cases of collision. Thus, under Constantine, the church obtained protection and support, but in many cases at the expense of its independence. It rose politically and sunk morally at the same time. Piety and learning and missionary zeal retired more and more to the desert. Ambition both in church and state was renounced by the more devout, that in a life of meditation and prayer, and of poverty, after the example of Christ, they might live only for the world to come, and for the spiritual interests of mankind. Many of the greatest and best men of the early church chose this mode of life. In after times monasticism wore a very different aspect. The population of Christendom underwent great changes during the period introduced by Constantine and closed by Charlemagne. While paganism was completely extinguished, and Christianity was carried into Persia and even to India and Abyssinia, the Mohammedan power, taking its rise in Arabia, blotted out Christianity from the map of Asia and Africa, of the eastern church left but feeble remains in Greece and Constantinople, seized upon a part of Spain, and threatened France, and indeed all the borders of the empire except the northern.

Still more were the fortunes of Christendom affected from another quarter. The German races, a more vigorous stock, subdued the degenerate and feeble inhabitants of the empire. The ancient Christianity was almost obliterated, and the loose nominal Christianity of Visigoths, Ostrogoths, Vandals, and Burgundians swept murderously over the south and west of Europe. Afterward the Franks and Saxons, and other German tribes, came nominally into the pale of Christendom, regenerating and invigorating it politically, but pouring into the church a semi-barbarous population, which it required centuries to subdue and civilize. The church had enough to do to manage the half-heathen population which was thus poured into its own bosom. Its missionary work was almost necessarily limited to its own borders. In the conversion of these tribes, the monks of Ireland, England, and the east of France had shown great zeal, and in prosecuting their work a large number nobly sacrificed their lives. But too many among these German tribes were converted either as soldiers at the command of their royal leaders, or as subdued enemies by authority of their conquerors. The banks of the Elbe were for two centuries wet with human gore by such contests between the German and Slavic races. With a population so introduced into the church, it is not strange that the wild, tumultuous character of the middle ages should show itself as much in the church as in the state. Herein lies the cause, if not the justification, of the Roman hierarchy. The concentrated authority of all Christendom, backed by the awful sanctions of religion, was, by the ecclesiastics of the age, deemed necessary in order to hold these fierce spirits in check. Certainly in the first half of this long period the nations of western Europe were indebted in no small degree to the church for the order that prevailed in society. Many other causes, indeed, coöperated to elevate the hierarchy, and to complete its organization. The church, which in the time of the earliest heresies and of the persecutions strove after unity through the bishops and through synods, became in a higher degree a united catholic church under the influence of Constantine and of the general councils. Its organization more and more resembled that of the empire. Single churches governed by their pastors, the churches of the various dioceses governed by their respective bishops, the churches of a province governed by synods and metropolitans, and whole countries governed as patriarchates, all seemed to imply the highest unity in a single head similar to that of the empire. But all these parts of a general organization were not equally complete. The hierarchical system was somewhat variable. In after times some things were retained, some went into disuse, and some received further development. The unity of the church was weakened by the jealousy between the eastern and western churches, and between the Greek pa-

triarch and the Roman pontiff. The bishop of Rome was in the old capital of the empire, and the bishop of Constantinople in the new. The one capital had antiquity on its side, the other the presence of the Christian emperor and his court. When the division of the empire took place, and especially when the Western empire fell and a new Christian empire was established in the West by the Carolingians, the way was prepared for the complete separation of the Greek and Latin churches, which in the course of time ensued. The new Christian or German empire, called also the holy Roman empire, increased the power of the bishop of Rome in many important respects, but was a check in other respects. The temporal power and authority of the pope were in general increased, but his influence over the clergy in Germany was thereby in point of fact restricted. Both the German church and the Gallican in the course of time had a more or less national character, supported by the emperor of Germany and the king of France, who often arrayed themselves in opposition to Rome. This was the great contest which lasted for centuries. From the 8th century to the 11th the foundations of the papal system were strengthened. From that time to the end of the 13th century the Roman power steadily ascended till it reached its height. Its most elevated point morally was under the pontificate of Gregory VII. (1073-'85), but physically and outwardly under that of Innocent III. (1198-1216). The higher ecclesiastics were more and more secular; they were chosen from the families of princes for the sake of bringing them under the influence of the state. The right of investiture became an important question between the emperor or king and the bishop of Rome. What the former sought to obtain by the appointment of their favorites, the latter sought to nullify by oaths of allegiance. The emperor relied much on his archbishops, often his own dependants; the pope diminished their power by making bishops depend more on himself than on their immediate superiors. Thus, while the higher clergy were more intent on the government than on the instruction of the church, the people became ignorant, and a general deterioration in morals was the consequence. For more than a century before the time of Luther there was a wide-spread sense of the need of church reform. The great writers of the age urged its necessity; the pope admitted it; the emperors authoritatively demanded it; the councils undertook to accomplish it, but all without effect. The motive was one of policy no less than of religious duty; and when the parties came to act together, it was found that their interests clashed, and that they were rather opposed to each other than united in policy. These things, confessed on all hands to be hopelessly bad, were growing worse and worse till the sudden breaking out of the German reformation.—*Third period, from the time of the reformation to the present.* The

seeds of the reformation were sown far back in the darkness of the middle ages. New historical investigations are continually bringing to light reformers before the reformation. Besides the opposition already referred to, partly of a political and national, and partly of an ascetic character, there were in England, France, Germany, and Bohemia many discontented individuals who were not satisfied with the character of the church and of its ministers, were weary of the venality of the higher officers and of the general corruption which had crept into sacred places, and longed for a return to what they deemed the Christianity of primitive times. Among these men Wycliffe was the most eminent. His doctrines were conveyed from Oxford to Prague by travelling students. The way for a movement in favor of reformation in the latter place was furthermore prepared by two or three distinguished Bohemian preachers, and then Huss appeared upon the stage, followed by Jerome of Prague, and kindled a fire which has never since been extinguished. In Germany sprang up those "reformers before the reformation" described by Ullmann, who in their retirement exerted a more silent but hardly less effective influence. When Luther, with Herculean strength, and with means not always the most delicately chosen, took up the work of reform, it was in no small degree the state of the public mind which made his words fly like lightning from one end of Europe to the other. The broadest distinction, perhaps, between Protestantism and Catholicism, is that the one is Biblical and the other traditionary; the one maintaining the right of private judgment, the other the paramount authority of the church. The foundation of the former is the Bible alone; that of the latter tradition, as comprehending the Bible and its canonical authority. According to the one theory, the Holy Spirit attends the written word and its ministry; according to the other, it descends through the church, its ministers and ordinances. With the one, the preaching of the gospel is the principal means of edifying the people; with the other, the sacraments of the church, various forms of adoration, sacerdotal offices, and ritual observances, are the means employed. With the one, there is no mediator between the soul and Christ, every believer being himself regarded as a priest, and enjoying direct and unrestricted access to God, through Christ alone; with the other, the Holy Mother and a multitude of departed saints are intercessors for man. Luther and the other reformers put aside all these mediators, in order that Christ might be the only mediator; rejected the authority of tradition, and all institutions and observances depending on it, except those which were tolerated as indifferent; substituted preaching for the ceremonies of the church; and were especially zealous against indulgences, against the mass, and against the authority of the Roman see. They asserted that the Roman church was but a

modified Judaism, a system of law and observances; that personal merit by works took the place of justification by faith. In addition to these and other theoretical differences, and the objections growing out of them, there was a long list of alleged abuses, which the reformers freely used to give point to their invectives. Among these they referred to the profligacy of the Roman court, the simony almost universally practised, the neglect of the Scriptures, the ignorance, idleness, and vices of the monks, the sale of indulgences, the draining of the coffers both of the rich and the poor on various pretences, the saying of masses for the souls of the departed, and the practice of holding religious services in a dead language, and leaving the people in a general state of ignorance, and then taking advantage of that ignorance for purposes of ambition. In the writings of the reformers, and especially in those of Luther, we find a perpetual recurrence to these and similar topics. The reformation commenced on similar principles, and nearly at the same time, in Germany and in Switzerland. Both Luther in Wittenberg and Zwingli in Zürich set themselves openly and resolutely against the sale of indulgences. The clergy, on the other hand, defended indulgences as a part of the established ecclesiastical system, and this controversy led by degrees to a questioning, and finally to a denial of the system itself. Both the reformers insisted on removing from the church whatever doctrines and principles were without foundation in the Bible. They came independently to the same conclusion in this respect, and were thus accidentally united in their opposition to the papacy. But in their positive construction of Christianity they represented different tendencies. Luther was more mystical, and allowed of more historical development in the church. Zwingli and his followers had less feeling, less imagination, less love of mystery, and represented rather the philosophic and rationalistic tendency in religion. The terms mystical and rationalistic are here used in a good sense. Nothing was better adapted to bring out the peculiarities of both orders of mind and types of theology than the question of the eucharist. While both rejected the Catholic doctrine of transubstantiation as unscriptural and unreasonable, Luther adopted a theory, somewhat inaccurately termed consubstantiation, as mysterious and inexplicable as that which he rejected; while Zwingli stripped the whole subject of its mystery, and exhibited it as a plain and simple emblematical rite, just as it is now viewed by most Protestant denominations in this country. The appearance of Calvin at Geneva, and his powerful metaphysical genius, gave a decidedly metaphysical and logical cast to the theology of the Reformed (Calvinistic) church, distinguishing it from that of the Lutheran church. The *Loci Communes* of Melancthon and the "Institutes" of Calvin, the most celebrated Protestant theological productions of the age, favorably represent the ground type, as the

Germans would say, of the theology of the two confessions. Perhaps, in the more logical character of the Reformed churches, as distinguished from the Lutheran, the reason predominating over the feelings, is to be found the cause of their greater individuality in matters of opinion, and greater diversity of creeds in different cities of Switzerland, and in different countries of Europe. The fact is unquestionable that the Lutheran church was much more homogeneous and united than the Reformed. In general the south of Europe remained Catholic, while the north became Protestant; and of Protestant countries, Switzerland and the west were Reformed, while the east, that is, the most of Germany and Denmark, Sweden and Norway, were Lutheran. The Genevan church was the model for France, Holland, Scotland, and in part for England, and consequently for North America. In the opinion of many Lutheran writers, the prominence given to the understanding over the religious sentiment in the Reformed church is the reason why Socinianism flourishes so much more in that church than in their own. The Reformed theologians, in turn, find in the mysticism of the Lutheran theology the cause of that revulsion of which rationalism is the result. We leave these points for others to decide. United as the church and state were in the 16th century, a reformation in religion could not take place without political convulsions. Not only were the Swiss cantons and the German states, especially the northern and western, immediately affected by the religious change, but the political rights of Protestants in general were long and fiercely contested, and were conceded only after the desolations of a thirty years' religious war. By the peace of Westphalia, Protestants were, in respect to political rights, put on an equal footing with Catholics. Up to the time of the reformation there had always been Protestant elements in the Catholic church. Now these were drained off. The last appearance of anything kindred to Protestantism was in the Jansenists, and that was suppressed. The council of Trent established by its decrees an authoritative rule of the Catholic faith, confirming, though in very general terms, the mediæval theology, condemning Protestantism, and correcting some abuses no longer tolerable. It was the province of Jesuitism to make up for the loss sustained by the separation of the Protestants from the church by new conquests to the faith in heathen lands. By the missions of the Jesuits many converts were won in China, Japan, India, and America. At home, in Catholic countries, they have been a kind of standing army of the church. As they were very active and influential in the council of Trent through Laynez, the general of their order, and as their principles, with some slight exceptions, were the principles by which the church was maintained against Protestantism at home, and chiefly extended by means of missions abroad, it is hardly too much to say that up to the time of the suppression of the order in 1773 they were

the true exponents of the spirit that ruled in the Catholic church of that age. They were sacrificed to expediency, and were restored on a change of circumstances. But owing to the continued operation of those causes, in a greater or less degree, which led to their suppression, the nominal restoration of the order does not place it where it was before.—The Lutheran church has felt the influence of time still more than the Catholic. In the controversy between Luther and Erasmus on the liberty of the will, the former carried his church with him; but on the mind of Melancthon and some others the arguments of Erasmus made a deep impression. Before his death Melancthon, no longer restrained by Luther, who was now deceased, put forth views on this subject quite at variance with those held by Luther, and the Lutheran church followed Melancthon rather than Luther. Since the days of the reformers, the principal controversies of the Lutheran church have turned on the question whether the reformation should be further developed and completed, or whether it shall be considered as having received its completion and fixed character from Luther. This question has never been settled for the whole Lutheran church, but the two parties, taking opposite sides, have each contended, and are still contending, for victory. Crypto-Calvinism, the doctrine of Calvin in respect to the eucharist, was introduced into Saxony by the progressive party, which sprang from the school of Melancthon. It was afterward suppressed by the strict Lutherans, and condemned in the "Formula of Concord." The theologians of this school were more rigid in maintaining the authority of human creeds, after the manner of the scholastic dialecticians, than zealous in propagating a spiritual Christianity. As opposite extremes usually produce each other, so this called forth the pietistic school of Spener and Franke, who placed the Bible far above the creeds of their church. In opposition to both these parties sprang up, about the middle of the last century, the school of rationalists, who set aside the authority of all creeds, and acknowledge the authority of the Bible only in a modified sense. After a century of triumph it seems to be approaching its dissolution, and the Lutheran theologians are returning either to their old orthodoxy, or to an evangelical faith founded upon a deeper study and truer interpretation of the Scriptures than was possible before the rise of rationalism. So the parties now stand divided more than ever on the question whether the normal Christianity of the church is that which has been handed down from the reformers, or that broad historical Christianity brought to light by a more extended and more critical study both of the Scriptures and of history.—In the Reformed church, Geneva was as much the centre of influence as Wittenberg was in the Lutheran. The preëminence of Zürich was limited to the lifetime of Zwingli. After his death Calvin rallied the forces of the Swiss

churches, and guided them with unsurpassed ability and energy. Besides, he wrote for all who used the French language, as Luther did for those who used the German. Luther was a practical leader, and controlled alike the thoughts, feelings, and actions of his followers. Calvin, more learned and more philosophic, aimed chiefly to master the intellects of men, and in this lay his great power out of his own city. Luther never wrote so complete a work as the "Institutes" of Calvin, nor are his commentaries so well adapted to all countries and all ages as are Calvin's. The Genevan reformer, though educated for the bar, was much more rigid in his views of Christian morality than was the monk of Wittenberg. Luther, while he aimed to put men right on the main points of morality, was content with the spirit of Christianity, and was quite easy about the particular acts of the individual. He was the advocate of great freedom in the individual, and allowed him to choose his own pleasures and amusements. He was even jovial in his own character. Calvin was just the opposite of all this. The churches founded by these great men differ as much, in respect to freedom or strictness of Christian conduct, as they themselves did. What was called a Christian life in Wittenberg would have been pronounced unchristian in Geneva. While Luther lamented the easy and lax morality of Wittenberg toward the end of life, without any attempt to control it by church discipline, Calvin was in a state of constant warfare with the "libertines" of Geneva in the matter of discipline. These two different types of Christian character are observable in the whole history of the two confessions. The Genevan church maintained its character through the 16th and 17th centuries, but during the 18th it gradually relaxed its theology, and in the beginning of the 19th was decidedly Socinian.—From Geneva proceeded, chiefly through Calvin and Beza, those influences which introduced the doctrines of the reformation into France. During the life of Beza, the Huguenots, as the French Protestants were called, became a numerous and powerful party; but for the greater part of three centuries they were persecuted by the French government. Twenty thousand or more perished in one month. Twenty-six years later, Henry IV., who had been educated in their faith, secured to them a political existence by the edict of Nantes, after which they flourished again in France for nearly a century. They had distinguished schools of theology at Saumur and Sedan, and numbered among their theologians such men as Blondel, Daillé, Bochart, Basnage, Beausobre, and Saurin. By the revocation of that edict by Louis XIV., hundreds of thousands of Huguenots were driven into exile. The refugees filled large cities and districts in several Protestant countries, particularly in the Netherlands and in Brandenburg. Now followed the period of "the church in the desert," during which, in the

Cévennes mountains and other secret retreats, the Huguenots held their stealthy communions. The French revolution again brought them liberty, since which they have experienced the various fortunes to which the people of France have been subject.—The reformation made its appearance at an early period in the Netherlands. But the emperor Charles V., and after him Philip II., resorted to the severest measures in order to crush it out. The people endured this rigor for a long time, and then they resisted, and finally established their independence. The church, henceforth connected with Geneva rather than with Wittenberg, held its first synod at Dort in 1574, and the next year founded the university of Leyden. The most remarkable feature of the church of the United Provinces was the celebrated Arminian controversy. Arminius and others resisted Calvin's doctrine of predestination. The matter was brought before the synod of Dort, and, as most of the clergy had been educated at Geneva, the doctrines of the Remonstrants, as the followers of Arminius were called, were condemned. Though the Arminian church never acquired a position of great influence in Holland, its leading men, among whom were Grotius, Episcopius, Curcellæus, Limborch, Le Clerc, and Wetstein, formed a school of wide-spread and lasting influence in the literary world. The Remonstrants became more and more latitudinarian in their views, and verged toward Socinianism far more than toward Calvinism. The Reformed church in Holland, though softened in the tone of its theology, has undergone much less change in its faith than the Swiss or the German church.—In England the doctrines of the Swiss reformers have had a peculiar fortune, owing partly to political and partly to other causes. The attitude of Henry VIII. toward Luther was unfavorable to the introduction of Lutheranism into England. Distinguished theologians from Strasburg sympathizing with the Swiss reformers, of whom Bucer and Peter Martyr are most known, were employed to aid Cranmer in carrying forward the work of reformation under Edward VI. Mary's troubled reign followed. English Protestants fled to the continent, where they became acquainted with Calvin and the spirit of the reformation introduced by him. On Elizabeth's accession to the throne, the reformation, begun by Edward, was carried through mainly on the principles of the Reformed church in respect to doctrines, but modified by Lutheran principles in respect to ecclesiastical organization and the ritual. Not that the Lutheran church government and liturgy were copied, but that Luther's theory in respect to the extent to which the ancient usages of the church might be retained was adopted. The church of England merely retained a little more both of the liturgy and of the government of the Catholic church than the Lutheran church did. It may be said in general terms that the Anglican church is eclectic,

combining Calvinistic, Lutheran, and Catholic elements, while the Puritans of England adhered more strictly to the Reformed church. In England the history of Christianity and the history of the government are so connected that the one cannot be understood apart from the other. High-churchism and toryism go hand in hand, while the moderate party and the dissenters favor the progress of liberty. England, too, has had its crisis of unbelief. The English deists exerted great influence both in their own country and in other countries of Europe. But in no country has the church been truer to herself in the defence of Christianity than in England. More eminent, perhaps, in antiquarian than in Biblical learning, she presents a body of Christian literature which, as a whole, will bear comparison with that of any other country. The bishops of England have in this respect been outdone by the prelates of no other church.—Nowhere have the principles of the Genevan church been carried out more fully than in Scotland. Knox not only knew Calvin and his followers intimately, but deeply sympathized with them. He was a Presbyterian by nature and by temperament as well as by conviction; and the Scottish character in general, with its metaphysical tendencies, seems to be adapted to that type of theology and that form of religion. The Scottish church has maintained much of its original character through all the changing scenes of its history. It could neither be terrified by the Stuarts, nor bribed by pecuniary rewards or honors. The present Free church of Scotland is but a single specimen of the spirit and courage with which it has always been accustomed to face difficulties and dangers. The tendency to unbelief manifested in Edinburgh a generation ago was happily arrested by Chalmers, who was an ornament and a bulwark of his church.—Though scarcely any church of western Europe is without its representatives in the United States, the great bulk of the early emigrants to this country belonged to some one of the numerous branches of the Reformed church. Nearly all these churches have undergone some modifications in this country, more perceptible, perhaps, to Europeans than to ourselves. It is a common remark of intelligent foreigners, that with all the diversities of Christian sects among us, there is a general resemblance, apparently growing out of the entire freedom of religious development in our country. An ardent love of religious liberty, shared by all Christian denominations in common, a freedom from all entanglements with the state, and a strong aversion to the union of church and state, distinguish American Christians, and separate them widely from those of any other country. Hence, with all the diversities of creeds and forms of worship, there is not only a very catholic spirit, but a marked sentiment of Christian union, showing itself in harmonious action in cities and towns where different communions are thrown to-

gether, and in formal coöperation in societies of Christian benevolence. The relative position of the various Christian denominations in this country has greatly changed during the past century. The orthodox Congregationalists, less predominant in New England than formerly, have spread by emigration into the western and middle states. They now constitute but one branch of the old church, the Unitarians constituting the other and more rationalistic branch. Indeed, the theology of the Congregationalists of New England is never so perfectly settled as that of some other denominations. Every half century and every important locality has had its school of theology. This is not said in reproach. It is the natural and necessary result of giving to the intellect so great prominence in religion. The same cause not only prevents a "dead orthodoxy," a stagnation in theology, but makes them a highly intellectual and enlightened body of Christians, the best friends of learning and of education in general. The Presbyterians, having settled at first in the middle and southern states, consisting mostly of emigrants from Scotland and the north of Ireland, seem also to have in some degree a local habitation. The bulk of their population and their strength is still in those states. They expand, not in the direction of New England, but of the western states. Like the Congregationalists, most of the different branches of Presbyterians have maintained an educated ministry, who have exerted a very great influence. The reunion of the Old School and New School Presbyterians in 1870, after a separation of more than 30 years, is one of the most noteworthy events of our time. The Episcopal church, which was somewhat checked by the revolutionary war, and was somewhat local in the beginning, is constantly manifesting fresh vigor and showing its power to go wherever wealth and refinement invite it. As in England it originally took an intermediate position between the Calvinists, Lutherans, and Catholics, so in this country at the present day it avoids all extremes in theology, and holds a sort of middle ground between the pietistic sects and their extreme opposites. Avoiding theological discussion, both in books and in the pulpit, giving less prominence to preaching than most other Protestant communions, the Episcopalians aim less at profound erudition than the Congregationalists and Presbyterians in preparing their candidates for the ministry, and consequently place less dependence on theological seminaries. In this respect they follow the example of their English brethren. But it must not hence be inferred that they have not an educated clergy. On the contrary, their clergy are generally accomplished scholars, but their study is more in the line of English literature, and in the rich literature of their own church, than in exegetical and doctrinal theology. An educated man rarely hears anything offensive to his taste in the discourses or other religious

services of an Episcopal clergyman. The Baptists and Methodists, though small in numbers at the first, have had a large increase from the common people in all parts of the country. Though differing in their creed, in their organization, and in their forms of religious service, they both lay great stress upon the experimental element in religion. The religion of the heart, drawn out distinctly in individual experience, they have always placed far above the religion of the intellect. Hence they have never made learning a requisite for the ministry. Though they have made great progress in education, and are no longer limited to the lower or even middling classes in the community, still their great strength lies in these classes. The Baptists are more nearly allied to the Congregationalists, both in doctrine and in practice, and the Methodists to the Episcopalians in church government, and to the Moravians in their religious spirit. In point of numbers they are the largest of the Protestant denominations. The Universalists, whose distinctive tenet is the final salvation of the whole human family, have made their appearance in American ecclesiastical history since the middle of the last century, and have received numerous accessions from most of the above named Christian sects.—The Roman Catholic church, as represented by the highest authorities in that communion, maintains her prominent position in Christian history. During the last three centuries she has been forced by the Protestant movement to pass through a severe ordeal, in which all her constituent elements were put to the test; but, as they believe, she has emerged from the trial with undiminished vigor and brightness. Soon after the reformation had proclaimed that free private judgment was the right of man and the rule of faith, she was called, even more perhaps than Protestant communions, to defend the system of revealed religion against the assaults of infidelity and atheism. Subsequent to the breaking out of the French revolution, she was subjected in France to indignity and oppression from the civil power; her priests were scattered or put to death, bishops were exiled, popes were abducted and thrown into prison; but she came to see her adversaries baffled, her claims recognized, and her hierarchy restored. She has since endured the sorrow and waste of social and civil warfare in every one of her ancient possessions, and the loss of the pope's temporal power in Rome; but, as her disciples contend, modern innovation has been able only to retard her life march for brief intervals. They still further allege that her growth and expansion in most Protestant countries cannot be denied, while in Catholic nations a daily increasing number of the faithful are devoting themselves to the strict practice of her law and the upholding of her authority. Though, in her collision with modern political and social systems, she, unlike other organizations, has been forced to

no change of principles, she has nevertheless been able to throw off many old abuses and alliances that served more to encumber than to adorn her. This self-reforming and self-renovating power is claimed by Catholic writers as a proof of the constitutional strength of that church, and, combined with unity of faith, sanctity in moral teaching, universality in time and place, and unbroken apostolic succession, as a mark of the Divine presence. The present condition of the Catholic church, as they hold, is inferior to no period of her past history, in the learning and efficiency of her clergy, in her many educational establishments, her missionary enterprises extending over almost every portion of the known world, her active associations for the exercise of every form of Christian benevolence. America, according to views recently propounded in this country, offers a new field to the ancient faith for the display of its diversified energies. Here, for the first time in the world's history, the Catholic church finds herself free from all entangling alliances with the civil government, and thus avoids a great source of distrust and dislike on the part of her opponents. Here, persecution, if it should occur at all, either for or against her interests, would be the result of transitory passions, not of the system of government by which the country is ruled. Here, the very conservatism which in the old world has made her so many enemies is claimed as a title to respect; in view of the necessity of vigorous principles to counteract the impetuous rush of unrestrained political freedom, and the often erratic intellectuality of a transitional and protesting age. In the United States the progress of the Roman Catholic church is evinced by the large army of ecclesiastics who have gradually spread from the solitary cathedral in Baltimore, where Carroll exercised episcopal functions, to the most distant parts of the land; by the numerous churches, schools, convents, asylums, and hospitals that she has everywhere erected; by her incessant labors among the great mass of emigrants who are sent to her door by the policy of European governments; by the frequent accessions to her ranks from the strictest anti-Catholic communions; and by the first fruits of a Catholic literature which is believed to promise largely for the future.—What conclusion in respect to the future can be drawn from the history of the past? Has Christianity a prospect of perpetuity and increase, or is it threatened with decay? It must be remembered that Christianity is not wholly limited to the church. Many elements of its power are felt elsewhere. The philosophy of government at the present day is preëminently Christian. The theory of human rights and of social progress differs from ancient theories in having a Christian basis. The literature of the civilized world is more and more a Christian literature. A Christian philanthropy is breathed into poetry and romance, as well as

into social and political life, more than in any former age. The public sentiment is deeply imbued with the principles of a Christian civilization. Christian nations and races of men are the dominant nations and races of the earth. Christian civilization at this moment, more than ever before, seems destined to spread over all Asia, Africa, and the islands of the great oceans. The paganism of the world is evidently to share the fate of the paganism of the old Roman empire, to fade away before Christianity, and become a mere matter of history. Is it probable that in Christendom itself Christianity will be compelled to yield to philosophical skepticism? Never did Christianity stand stronger in England than after its contest with deism. Never did the philosophic mind of France grasp it with more power than after atheism had spent all its force. There probably was never a time nor a country in which a historical Christianity could be maintained against the fiercest assaults of a skeptical philosophy with such a convincing power as in Germany at this time. That false rationalism which is essentially at variance with Christianity, deistically denying whatever is supernatural, has been already overcome. Nowhere, during the whole history of the church, has the defence of Christianity been conducted with such critical learning and philosophic power as in Germany, by the great theologians of the present century. Such a historical groundwork of Christianity as Neander has presented to the world in his history of the church, it is vain to look for in any former age. Indeed, history now, civil as well as ecclesiastical, is the impregnable fortress within which Christianity is securely intrenched. All the lines of philosophic history now converge in Christianity. Will the influence of sects and parties destroy the efficacy of Christianity? In respect to these, there is not only change but progress. It has become a pretty generally received opinion among the leading men of all sects, that the whole truth is to be found in none of them; that each is working out some problem, more or less important, to be adopted ultimately by all; that a more comprehensive view of Christianity will be possible after the good and evil in every system have distinctly made themselves apparent to the whole world. The greatest men of the age are already striving more philosophically and more satisfactorily to answer the fundamental question, "How is Christianity to be conceived of as a whole?" The old theological conceptions of it are found to be inadequate in many particulars, chiefly by defect. The theologians were at fault sometimes in their metaphysics, sometimes in their criticism and interpretation of the Bible. Christianity is many-sided. The old theological systems were all more or less one-sided. One aspect of this great subject, it would seem, was supposed to comprehend the whole. A broader and more comprehensive study of the subject

was demanded. The accumulations of learning made during many generations needed to be more exactly analyzed and more carefully tested, and then classified on a much broader scale. All the approximations that have been made toward a clear and comprehensive view of the whole subject were to be studied with reference to a still greater enlargement. It is the manifest tendency of the public mind in this direction that distinguishes the present age. There is a reaching after a universal and complete Christianity—that is, the true historical Christianity, not the limited, partial Christianity of a particular school. Almost every party shows a disposition to appropriate whatever of truth or of excellence may be found in any other party. All seem to aim at a wider grasp of Christianity as a whole.

CHRISTIANS (the first syllable is usually but improperly pronounced as in Christ), or **Christian Connection**, a Christian sect which arose in the United States near the beginning of the present century. At their organization they adopted the appellation Christians as their only name, declared the Bible their only authoritative rule of faith and practice, and extended their fellowship to all Christians, irrespective of creed or party. They originated simultaneously in the east, west, and south, their three distinct sources having at first no knowledge of each other. In North Carolina, in 1793, a secession took place from the Methodist Episcopal church, on grounds of church government; and the seceding body, at first known as "Republican Methodists," subsequently, through the influence of the Rev. J. O'Kelley and others, adopted the name of Christians. The second source was in New England, chiefly in Vermont. In 1800 Dr. Abner Jones, Elias Smith, and other members of Baptist churches, becoming dissatisfied with sectarian creeds and denominations, proposed the principles now held by the Christians. The first church organized by them was in Lyndon, Vt., and many churches had been founded as early as 1804. In 1808 the "Herald of Gospel Liberty," one of the earliest religious newspapers in the United States, was first published by Mr. Smith. The third source had its seat in Kentucky and Tennessee. After the great revival which spread through the Presbyterian church in those states in 1800, several ministers, among whom were B. W. Stone and D. Purviance, desired broader grounds of union, and five of whom in 1801 withdrew from the synod of Kentucky. They organized a new presbytery, called the Springfield presbytery, formally proclaimed their principles, June 28, 1804, and soon after adopted the name of Christians. The three kindred bodies which had thus, between 1793 and 1804, arisen separately, soon after met in general convention and were consolidated into a single denomination. They are generally Antitrinitarians and Baptists, cherish prayer meetings, Sunday schools, and missionary enterprises, do not confine their fellowship

to the baptized, are congregational in church government, and have annual and state conferences, and a quadrennial general convention. When the war interrupted the connection of the southern with the northern conferences, the former organized the "Southern Christian Convention," which in 1873 still maintained its separate existence. Among their more prominent clergymen and writers may be mentioned Walter, Clough, Badger, Millard, Ross, Summerbell, Holland, Kincaid, and Plummer. Their institutions of learning in 1872 were the Christian Union college, at Merom, Ind.; the Wolfboro academy, at Wolfboro, N. H.; Starkey academy, at Eddytown, N. Y.; a Biblical school, likewise at Eddytown; and the Le Grand Christian institute, at Le Grand, Iowa. In 1872 there were in the northern states and Canada 65 conferences, 997 ordained and 201 unordained ministers (in 62 conferences), 1,074 societies with 552 church edifices (in 60 conferences), 56,958 members (in 59 conferences), and church property valued at \$908,775; in the southern general convention, 72 ordained ministers, 18 licentiates, and 10,581 members. The "Herald of Gospel Liberty," united some years ago with the "Gospel Herald" of Dayton, Ohio, where it is now published, remains the principal organ of the denomination. The "Christian Sun," published at Suffolk, Va., is the organ of the southern general convention.

CHRISTIANSAND. I. The southernmost province (*stift* or diocese) of Norway, bordering on the provinces of Bergen and Christiania, the North sea, and the Skager Rack; area, 15,400 sq. m.; pop. in 1865, 328,742. It is traversed by numerous mountains and small rivers, and includes many islands. The coast is broken, especially on the west, where it is penetrated by the extensive Bukke bay or fiord, with two branches, the northern and larger being the Nærstrand, and the southern the Lyse fiord. The N. E. district of Upper Tellemarken or Bratsberg is among the most mountainous. The numerous clefts are filled with water, which rushes down in rapids and cataracts with tremendous velocity, and the waterfall of the Rinkan Foss is over 400 ft. high. These waters unite in three streams and fall into the lake of Nord Söen, whence rises a powerful and impetuous river, the Skeen or Brevig. The other chief rivers are the Nid and the Torrisdal. The fine color of the water, the rocky banks, and the whole scenery produce a remarkably picturesque effect. In the southern districts there are large and fertile valleys, and the climate is very mild, considering the high latitude. The principal wealth of the province consists in forests of oak, pine, fir, and birch, supplying materials for making fishing boats and for the export of planks and deals. Lobsters are not found in any part of the world in greater quantities than along the S. coast of this province between Hellesund and Lister fiord. The principal mineral is iron, and the great abundance of fuel offers facilities for smelting it. The population

is remarkable for its hardiness, laboriousness, and tall stature. **II.** A city, capital of the province, situated upon a deep bay called Topdals fiord, which makes into the land from the Skager Rack, a few miles E. of the Lindesnäs, or South cape of Norway; pop. in 1870, 11,468. The situation is picturesque, and the town is regularly built. Many of the houses, chiefly of wood, are surrounded with gardens. The cathedral, a Gothic structure of gray stone, is only second in size and interest to that of Drontheim. Ship building has somewhat declined owing to the diminished abundance of timber consequent upon the clearing of some of the forests; but trade and navigation are active. The principal exports are timber, fish, hides, copper, and iron. During the lobster season over 20 smacks are regularly employed in shipping lobsters to London. Tobacco and other articles are manufactured to some extent. The town is defended by a fortress at the entrance to the fine harbor on the island of Odderö, which divides it into two parts. Christiansand was founded in 1641 by Christian IV., king of Denmark and Norway.

CHRISTIANS OF ST. JOHN, Disciples of St. John, Nazareans, Mendæans, or Sabæans, designations applied indiscriminately, and with great confusion, to a sect of religionists now only found in Persia, chiefly in the neighborhood of Bassorah. They are not Christians in any sense, as they assert Jesus to be an impostor, and install John the Baptist in his place. They claim to have existed from his time, and consider their origin to have been on the banks of the Jordan. They account for their present locality by asserting that the Mohammedans drove them away from Palestine, some to Persia, and some to India. They afterward joined the Nestorians to avoid another persecution, and allowed themselves to be called Christians. They were separated again from the Nestorians more than 300 years ago. Critics and historians are divided in opinion as to their origin. Neander thinks that the name Mendæans signifies disciples, and Sabæans, baptizers; and that the sect took its origin from those disciples of John the Baptist who, after the martyrdom of their master, adopted a course hostile to Christianity, and that from them afterward sprung up this sect, formed out of the elements of an older eastern theosophy. Their doctrines are, however, well defined. They consider the Jehovah of the Old Testament a spurious God, and the Christ of the New a false teacher. They consider the world to have been created by gloomy angels, who belong to the kingdom of darkness, of whom there are seven, who inhabit the seven planets, while there is also a kingdom of light, superintended by good angels. Back of these kingdoms, in unspeakable splendor, is the supreme original being, Ferha, and the female principle, Ajar. Darkness triumphs over light, but there is a struggle between the two kingdoms, and through successive revelations to the kingdom of light, and so

to the world, the rule of darkness is to be broken. The Jewish system was not such a revelation; it came from the realm of darkness. So did that of Jesus. But in John the Baptist they hold that the revelation was from the kingdom of light. The means of introducing men to that kingdom is baptism. John they relate to have been born from a kiss of Zachariah. They also say that John himself was married, but that his children sprung out of the Jordan. They have five sacred books, four of them doctrinal, and the fifth on astrology. They consider baptism as the great and only means of forgiveness and salvation. They prohibit mourning for the dead, tolerate polygamy even among the priests, and forbid the "elect," or those advanced to the higher degrees of the faith, to use sensual indulgences, or to sing or dance. They keep a sort of festival resembling the agape of the primitive Christians, and have a singular antipathy to blue color. In the middle of the 17th century, when they first became known through the Persian missionaries, there were supposed to be from 20,000 to 25,000 families of them.

CHRISTIANS OF ST. THOMAS, a branch of the ancient Syro-Persian church, established on the coast of Malabar. They have a tradition that St. Thomas himself preached the gospel to them, and established their church. The earliest certain history we have of the Syro-Persian church is in a writer of the 6th century. It was formed by the union of the excommunicated Nestorians (499) who held to the Monophysite doctrine. In their practices and doctrines they claim to be primitive. They still celebrate the agape, commemorate the Lord's supper with bread, salt, and oil, and anoint the body of the infant at the time of baptism. Their priests shave the head, and are allowed to marry. They use the Syriac language in the liturgy. During the Portuguese occupancy of the country they submitted to the Catholic church; but when the Dutch obtained the ascendancy the Nestorians resumed their ecclesiastical independence, and still preserve it.

CHRISTIANSTAD, a fortified town of Sweden, capital of the län or district of the same name, in the province of Gothland, 262 m. S. S. W. of Stockholm; pop. in 1868, 7,710. It is built upon a little promontory in a lake formed by the Helge-å, 10 m. from Åhus, its port on the Baltic. The town has a good aspect. The crown house, on the N. side of the great square, for government and garrison purposes, a single large church of the year 1628, a lazaretto, a theatre, and school houses are among the principal buildings. The harbor of Åhus is open, but tolerably safe. The trade is chiefly with Lübeck, Russia, Denmark, and England. Much domestic brandy is sent to Stockholm. Christianstad was founded by Christian IV. of Denmark in 1614, the southern part of Sweden being at that time a Danish possession. The place suffered much during the frequent wars between Sweden and Den-

Christianstad.

mark. In 1678 it was nearly destroyed by Charles XI. of Sweden, during his contest with Christian V. of Denmark. It was rebuilt in 1710 and 1748.

CHRISTIANSTED, a town, capital of the island of St. Croix and of the Danish West Indies; pop. about 6,000. It has a good harbor, defended by Fort Christiansværn, and a battery, contains a Danish and an English church, and a bank, and is the chief entrepot of commerce with Copenhagen.

CHRISTIANSUND, a seaport town of Norway, in the province and 85 m. S. W. of Drontheim, on the North sea, at the mouth of the Thingve fiord; lat. 63° 10' N.; pop. in 1866, 5,709. It is built upon three islands, Kirkland, Nordland, and Inland, which enclose a singularly pretty harbor, in form almost circular. The view of the town is completely shut off on the seaward side. The houses, uniformly red and of wood, are grouped together in picturesque disorder. The place is thriving, the trade being chiefly in cured fish (cod), which is exported hence to Spain and the Mediterranean, also to the West Indies. It was founded in 1734 by Christian VI. of Denmark.

CHRISTINA, queen of Spain. See **MARIA CHRISTINA**.

CHRISTINA, queen of Sweden, the only legitimate child of Gustavus Adolphus who survived infancy, born in Stockholm, Dec. 8, 1626, died in Rome, April 19, 1689. She was but six years of age when her father died at Lützen, and she was early separated from her mother, and sent to be educated under the eye of her aunt, the princess Catharine, sister of Gustavus and consort of the count palatine John Casimir. She remained under his guardianship until the death of her aunt in 1638. The young queen's early education does not appear to have been judicious or effective. The palatine court rather sought its own aggrandizement. The son of the princess, Charles Gustavus, afterward Charles X. of Sweden, was betrothed to Christina during this guardianship. She was educated in deep distrust of the guardians appointed by the diet to have

charge of her youth, and to govern the kingdom during her minority. In 1636 the diet declared its opinion concerning the mode of educating the young queen. Christina herself relates that her father had ordered that she should receive a masculine education. Her tutor, whom he had himself appointed, was John Matthiae, at first a professor in the college of nobles, and afterward the king's court preacher. Her progress in accomplishments of every kind was remarkable. At 18 she read Thucydides and Polybius in the original, and wrote and spoke Latin, German, and French. In council and administration she showed much acuteness; while the grace of her manners and personal demeanor at this period exercised great influence over all who approached her, although she affected rather to slight than to assert outward dignity. Her portrait during the height of her renown was elaborately drawn by Chanut, a French ambassador at her court. "Her countenance," he says, "changes with every change of mental emotion. For the most part she is pensive, and in every change of aspect she preserves something that is agreeable. If she disapprove of a remark made, her face is covered for a moment as with a cloud, which inspires terror. Her voice, usually mild, can nevertheless assume the strength of a man's. Her spirit is filled with incredible love of virtue, and she is passionately fond of honor. She talks about virtue like a stoical philosopher. There are times when she seems to lay her crown beneath her feet." Chanut then praises her gift of comprehension and retentiveness of memory; her love for the society of learned men and scientific conversation; her reserve in the treatment of public affairs, and in council; her valuation of secrecy, and her power to preserve it inviolate; her apparent mistrust, and the difficulty with which she was made to change her mind; her power over the senate and her council of state. She was a great horsewoman, often ten hours at a time in the saddle, and no hunter in her kingdom was a better marksman. Her character was essentially masculine, always avoid-

ing the society of her court ladies, and ever seeking conversation with men. She had a high sense of the value of time, devoting not more than a quarter of an hour to her toilet. Her observers at this time declare that she valued nothing but honor and virtue, and predicted that her extraordinary merit alone would make her reign illustrious, independent of foreign conquest and the valor of her armies. Such was the bright promise of her youth, the more remarkable from contrast with coming shadows. The administration of the regency during the minority of Christina was confided to a council of five members, at the head of whom was Oxenstiern, the chancellor of the late king. The death of this sovereign betokened great changes in the state of Europe. The German Protestants, now without a leader, were at once split up into factions. Their imperialist enemies, though worsted at Lützen (1632), prepared vigorously to renew the war. Oxenstiern was appointed by the Swedish regents to be "legate plenipotentiary of the Swedish crown in the Roman empire, and with all the armies." He proceeded to the theatre of war, and devoted all his great genius to finding resources for the support of the Protestant cause. Christina assumed the exercise of sovereignty Dec. 6, 1644. Her reign was begun most auspiciously under the guidance of the greatest statesman of the age. Her ingratitude was not slow to follow. The last victories of her army in Germany were hailed with rapture at home, and won for the commander his sovereign's cordial and graceful acknowledgments. Torstenson had overthrown the main army of the imperialists under Gallas. The remaining three years of the war were less brilliant in victories, but more remorselessly vindictive than the other periods. The closing year (1648) found France more than ever united with the Swedes. Turenne received orders to support the new Swedish general Wrangel with his whole force. They effected a junction after much difficulty, and carried on a war of utter devastation against Bavaria. Charles Gustavus, the cousin of the queen, arrived from Sweden with reinforcements, and with the commission of generalissimo. Christina had sent him to command the army in order to rid herself of his importunate courtship. He laid vigorous siege to Prague, which must soon have fallen had not the emperor Ferdinand III., dreading this catastrophe and the certain loss of Bohemia consequent upon it, resolved to arrest it by accepting terms of peace. The Swedes and French had overthrown every other power in Germany, and it remained for the emperor to make the best terms he could. Accordingly the treaty of Westphalia, securing Protestant liberty, was signed Oct. 24, 1648, simultaneously in Osnabrück and Münster. Sweden received money equivalent to \$5,300,000 for payment of her troops, and retained possession of Upper Pomerania, Rügen, Lower Pomerania up to the Oder, the delta of this river, with

Stettin, Gartz, Wismar, Bremen, and Verden, all as fiefs of the empire. Christina's desire for peace had been ardent during the negotiations. It was destined, however, to bring her greater cares and anxieties than she had suffered during the war. Throughout her dominions the great conflict left behind it internal derangements so vast that she soon resolved to commit the task to other hands. The war had been totally disproportioned to the forces of the country. A proper distribution of the burden became an insolvable problem. The internal balance of the state was profoundly disturbed, and there needed a creative spirit like that of Gustavus Adolphus to restore it upon new foundations. Oxenstiern had withdrawn from court, having lost favor with the queen. His influence had been eclipsed by unworthy favorites, and although he shortly returned to his post and to the direction of affairs, he failed to satisfy the country; less indeed from the infirmities of great age, as has been said, than from a new order of things which in its operations jostled him aside. The most deserved reproaches have been heaped upon Christina for her capricious and dissolute conduct at this time; but during great trials to which she was exposed, she gave proof of intellect and courage. She had brilliant merits to reward and many wrongs to redress, and the care which she gave to old and wounded soldiers demands great praise. She was young, vivacious, and liberal without stint. The registers of her reign are filled with deeds of alienation of crown property, patents of nobility, tokens of grace and gifts of every sort. But it was soon evident that personal favor was to become the source of benefactions exceeding all others in amount. A young favorite, the handsomest of her courtiers, Magnus de la Gardie, was enriched with an annual income of 80,000 rix dollars in landed estate alone. Other favorites in time eclipsed him. Her father had already offered to Grotius an asylum in Sweden; and Christina invited learned men to her court from every quarter of Europe. Among the number, Descartes was with the young sovereign at 5 o'clock every morning for two months, and the impression which this philosopher made upon her mind has been said to have given her the first bias to skepticism. The origin of her new tendency, however, is with better reason ascribed to her physician Bourdelot, who, having rescued her from a dangerous illness, prescribed gayety of life for the future, and imparted to his patient his own scorn of all religion. This man took the place of De la Gardie, and through him presently all the favors of the throne were dispensed. She was constantly urged by the diet and her council to marry. The prospects of the monarchy now inspired much apprehension; but although her hand was sought by many princes, the queen resolutely declined a matrimonial alliance. Her father had intended her for Frederick William, afterward the great elector of Bran-

denburg. The popular wish was for her cousin, Charles Gustavus, who moreover appears from his own account to have desired to marry her from motives independent of ambition. She made light of his affection, and told him he talked "nonsense—a chapter from a romance." The result was his positive rejection; but at the same time the queen resolved to abdicate the throne in his favor. She forthwith demanded that the diet should name her cousin successor to the throne. Oxenstiern and Torstenson in vain entreated her to abandon this purpose. The resolution naming her cousin successor to the throne was passed; and Oxenstiern, when obliged to sign it, declared that he would rather sign his own death warrant. He foresaw her abdication. One year later she made known this purpose. An independent life in other lands was now Christina's great desire, which was quickened by a fear that if she delayed, her renunciation of the crown would lose the lustre she wished to shed upon it through its perfect spontaneity. It began to be thought that the act might soon be forced upon her by the machinations of her enemies. A revolt was threatened, and Christina, desiring to quell this, and to abdicate voluntarily thereafter, allowed another diet to assemble without communicating to them her resolution. She carried out her purpose in the manner indicated; but the remainder of her reign was employed as though she had determined not to be regretted. Every species of abuse and license became her daily practice. The public treasure was squandered most dishonestly. She declared she would rather see the devil than her secretary with despatches. Months elapsed without her holding a council of state. She created in all 460 new nobles, among them the court tailor. The court was crowded with dancers, comedians, and singers. Ballets, in which the queen danced, and lascivious entertainments of every description, occupied the time of court and council. Public discontent began to rise to a formidable pitch, and at length Christina, in the 28th year of her age, announced that the time had arrived when she should carry out her purpose of abdication. The diet, assembled at Upsal, offered the usual remonstrances, but at length acceded, the high chancellor adding, "If this is to be, then the sooner the better." The solemn act of renunciation was to be on June 6, 1654, and the interim appears to have been spent by Christina in coming to terms in regard to her future allowance of money. The diet assigned her an income of 240,000 rix dollars a year; but before the matter could be definitely settled, it produced some altercation between the queen and council. At the ceremony of abdication Christina appeared in robes of state, with crown and sceptre, and after an address of farewell laid aside, one after the other, the various regalia. Descending then from the throne, she desired to see her successor, Prince Charles, take her place immediately. She

begged him to mount to the royal chair. This he would not do in her presence; but after attending Christina to her chamber, he returned to the great hall, and was crowned forthwith. Oxenstiern wept as the queen departed. "She is daughter still of our great Gustavus," he exclaimed. Twelve ships of war had been equipped to convey her across the Baltic; but she took her way by land to Denmark, dismissing all her Swedish attendants except four. On reaching a brook which then formed the southern boundary of Sweden, she alighted from her carriage, and leaping across it, she cried out, "Now I am free and out of Sweden, which I trust never to see again." Her country, however, soon became more estranged from her than she from it. Twice she revisited it, and on both occasions she was received and dismissed with distrust, if not with contumely. Carrying with her everything curious or valuable from the palace of her fathers, she abandoned her country as the abode of ignorance and barbarism. She travelled through Germany in the dress of a man, after having embraced the Catholic religion secretly at Brussels. Her public renunciation of Lutheranism was made soon after at Innsbruck. The Catholics regarded the fact as a great triumph, while the Protestants were shocked at the conduct of the daughter of Gustavus Adolphus. She was cordially welcomed by the pope, Alexander VII., and at her confirmation by him adopted the name of Alexandra. In 1656 she went to Paris, where she was received with much and various sensation. Her talents and learning were the wonder of that capital. The learned men of Europe continued to be her subjects, as it were; but she seemed to become more and more unsexed. Her masculine air and libertine conversation kept women of delicacy at a distance. Ninon de l'Enclos was the only woman in Paris whom she noticed with any marks of esteem. She offered to mediate between France and Spain; but Mazarin declined the offer, and, under various pretexts, caused her visit to Paris to be shortened as much as possible. In 1657 she returned, and the contempt with which she had now come to be regarded was changed to detestation and horror by a murder which she caused to be perpetrated at Fontainebleau, in the great gallery, almost in her own presence. Monaldeschi, her grand equerry and favorite, was believed by her to have betrayed her confidence. She sent for him, showed him a priest, and told him to prepare for death. The Italian, overcome with terror, cast himself at her feet and begged for mercy; but she, inexorable, ordered Sentinelli, the captain of her guards, to put him to death. The order was executed on the spot. The court of Louis XIV. expressed its displeasure at the act, and during two months she did not show herself publicly in Paris; but the crime was allowed to pass, not only without punishment, but without inquiry. In 1658 she returned to Rome, where she re-

ceived news that her revenue was cut off on account of the war between Sweden and Denmark and Poland. Pope Alexander VII. assigned her a pension of 12,000 scudi, and appointed Cardinal Azzolini to take charge of her finances. Her pride could not brook this state of affairs, and she demanded troops of the emperor to march against the Swedes. Not succeeding in her ambitious designs, she settled down to a life of literary ease and sensual indulgence. In 1660, on the death of the king of Sweden, she went to Stockholm, and began to intrigue for the recovery of the crown, but was compelled to sign another formal act of abdication. In 1666 she visited Sweden again, but found it prudent to return without going to Stockholm. On the death of John Casimir she aspired to the throne of Poland, but the Poles paying little attention to her demands, she returned to Rome and made her permanent residence there. She spent the rest of her life in the culture of letters and in correspondence with learned men, made vast collections of works of art and of books, and founded the Arcadian academy. (See *ACADEMY*.) She bequeathed her fortune to Cardinal Azzolini. She was interred in the church of St. Peter, and over her remains a magnificent monument bears a long inscription, although she had expressed a wish to have these simple words: *Vixit Christina annos LXIII*. Her collections of art were sold and scattered about the world; 900 precious MSS. are in the Vatican, and the most valuable of her paintings were removed in 1722 to Paris, having been bought by the duke of Orleans, regent of France. She left some writings (collected and published by Archenholz in his memoirs of her life, 4 vols. 4to, 1751), which, says Geijer, exhibit a soul ardent and untamed by years, striving in all things after the extreme and the supreme, but submitting at last. "The feminine virtues," he adds in conclusion, "which she despised, avenge themselves upon her good name; yet was she better than her reputation."—See Geijer's *Svenska Folkets Historia*; Lacombe's *Histoire de Christine*, and D'Alembert's *Mémoires et réflexions sur Christine, reine de la Suède* (both based upon the memoirs of Archenholz); Catteau-Calleville's *Histoire de Christine, reine de la Suède*; Grauert's *Christine, Königin von Schweden, und ihr Hof* (2 vols., Bonn, 1838-'42); and sketches in the works of Bayle and Voltaire.

CHRISTMAS (Christ and mass), a festival of the Christian church, observed on Dec. 25 as the anniversary of the birth of the Saviour. Its institution is attributed by the decretal letters to Pope Telesphorus, who died A. D. 138, and throughout the subsequent history of the church it has been one of the most noted of Christian solemnities. At first it was the most movable of the Christian festive days, often confounded with the Epiphany, and celebrated by the eastern churches in the months of April and May. In the 4th century the

urgency of St. Cyril of Jerusalem obtained from Pope Julius I. an order for an investigation to be made concerning the day of Christ's nativity. The result of inquiry by the theologians of the East and the West was an agreement upon the 25th of December. The chief grounds for the decision were the tables of the censors in the archives of Rome; and although, in the opinion of some of the fathers, there was not authentic proof of the identification of the day, yet the decision was uniformly accepted, and from that time the nativity has been celebrated throughout the church on the same day. It has also been a common tradition that Christ was born about the middle of the night. The custom in Roman Catholic countries of ushering in Christmas day by the celebration of three masses, one at midnight, the second at early dawn, and the third in the morning, dates from the 6th century. The day was considered in the double light of a holy commemoration and a cheerful festival, and was accordingly distinguished by devotion, by vacation from business, and by merriment. During the middle ages it was celebrated by the gay fantastic spectacle of dramatic mysteries and moralities, performed by personages in grotesque masks and singular costumes. The scenery usually represented an infant in a cradle, surrounded by the Virgin Mary and St. Joseph, by bulls' heads, cherubs, eastern magi, and manifold ornaments. The custom of singing canticles at Christmas, called carols, which recalled the songs of the shepherds at the birth of Christ, dates from the time when the common people ceased to understand Latin. The bishops and lower clergy often joined with the populace in carolling, and the songs were enlivened by dances and by the music of tambours, guitars, violins, and organs. Fathers, mothers, sons, and daughters mingled together in the dance; if in the night, each bearing in his hand a lighted wax taper. Many collections have been made of these naïve mediæval carols which filled the hours between the nocturnal masses, and which sometimes took the place of psalms in the churches. Of perhaps the oldest of these collections, only a single leaf remains, containing two carols, preserved in the Bodleian library, in a volume of "Christ-masse Carolles," printed by Wynkin de Worde in 1521. Davies Gilbert published a volume of "Ancient Christmas Carols," with the tunes to which they were formerly sung in England, and William Sandys made a more complete collection (London, 1833). The carols of the Welsh are especially celebrated, and their *Llyfr Carolan* ("Book of Carols") contains 66, and their *Blodeugardd Cymru* ("Anthology of Wales") contains 48. The German carols were collected by Weinhold (Graz, 1853), and one of the best of the many editions of French carols (*noëls*) was published at Poitiers in 1824. During the last days preceding Christmas it is still the custom for Calabrian minstrels to descend from the mountains

to Naples and Rome, saluting the shrines of the Virgin Mother with their wild music, under the poetical notion of cheering her until the birth time of her infant at the approaching Christmas. In a picture of the nativity by Raphael he has introduced a shepherd at the door playing on a sort of bagpipe. Preparatory to Christmas the bells are rung at dead midnight throughout England and the continent; and after the solemn celebration of the mass, for which the churches in France and Italy are magnificently adorned, it is usual for the revelers to partake of a collation (*réveillon*), that they may be better able to sustain the fatigues of the night. Among the revels of the Christmas season were the so-called feasts of fools and of asses, grotesque saturnalia, which were sometimes termed "December liberties," in which everything serious was burlesqued, inferiors personifying their superiors, great men becoming frolicsome, and all illustrating the proneness of man to occasionally reverse the order of society and ridicule its decencies.—In the Protestant districts of Germany and the north of Europe, Christmas is often called the "children's festival," and Christmas eve is devoted to giving presents, especially between parents and children, and brothers and sisters, by means of the so-called Christmas tree. A large yew bough is erected in one of the parlors, lighted with tapers, and hung with manifold gifts, sweetmeats, apples, nuts, playthings, and ornaments. Each of these is marked with the name of the person for whom it is intended, but not with the name of the donor, and when the whole family party is assembled, the presents are distributed around the room according to their labels, amid joyful acclamations and congratulations. A more sober scene succeeds, for the mother takes this occasion to say privately to the daughters, and the father to the sons, what has been observed most praiseworthy and what most faulty in their conduct. Formerly, and still in some of the smaller villages of North Germany, the presents made by all the parents were sent to some one person, who, in high buskins, a white robe, a mask, and an enormous flax wig, becoming the bugbear of children known as *Knecht Rupert*, goes from house to house, is received by the parents with great pomp and reverence, calls for the children, and bestows the intended gifts upon them according to the character which he hears from the parents after severe inquiries. A beautiful poem of Hebel, *Christ-Baum*, celebrates the German ceremonies on Christmas eve.—It is an old Swedish tradition, preserved in the history of Olaus, archbishop of Upsal, that at the festival of Christmas the men living in the cold northern parts are suddenly and strangely metamorphosed into wolves; and that a huge multitude of them meet together at an appointed place during the night, and rage so fiercely against mankind and other creatures not fierce by nature, that the inhabitants of that country suffer

more from their attacks than ever they do from natural wolves.—Christmas has always been at once a religious, domestic, and merry-making festival in England, equally for every rank and every age. The revels used to begin on Christmas eve, and continued often till Candlemas (Feb. 2), every day being a holiday till twelfth-night (Jan. 6). In the houses of the nobles a "lord of misrule" or "abbot of unreason" was appointed, whose office was "to make the rarest pastimes, to delight the beholder," and whose dominion lasted from "All-hallow eve" (Oct. 31) till Candlemas day. The larder was filled with capons, hens, turkeys, geese, ducks, beef, mutton, pork, pies, puddings, nuts, plums, sugar, and honey. The Italians have the following proverb: "He has more business than English ovens at Christmas." The tenants were entertained at the hall; and the lord of the manor and his family encouraged every art conducive to mirth.

On Christmas eve the bells were rung;
 On Christmas eve the mass was sung;
 That only night, in all the year,
 Saw the stoled priest the chalice rear.
 Then opened wide the baron's hall,
 To vassal, tenant, serf, and all;
 Power laid his rod of rule aside,
 And ceremony doffed his pride.
 The heir, with roses in his shoes,
 That night might village partner choose.
 All hailed, with uncontrolled delight
 And general voice, the happy night
 That to the cottage, as the crown,
 Brought tidings of salvation down.
 England was merry England when
 Old Christmas brought his sports again.
 'Twas Christmas broach'd the mightiest ale;
 'Twas Christmas told the merriest tale;
 A Christmas gambol oft would cheer
 A poor man's heart through half the year.

A glowing fire, made of great logs, the principal of which was termed the yule log or Christmas block, which might be burned till Candlemas eve, kept out the severity of the weather; and the abundance was shared amid music, conjuring, riddles, hot cockles, fool-plough, snap-dragon, jokes, laughter, repartees, forfeits, and dances. The generous wassail bowls and bowls of punch never failed to bring tumultuous joys. The favorite and first dish on Christmas day was a soused boar's head, which was borne to the principal table with great state and solemnity, "upon a silver platter, with ministralsye." The common custom of decking the houses and churches at Christmas with evergreens is derived from ancient druid practices. It was an old belief that sylvan spirits might flock to the evergreens, and remain unrippd by frost till a milder season. The holly, ivy, rosemary, bay, laurel, and mistletoe furnished the favorite trimmings, which were not removed till Candlemas. In old church calendars Christmas eve is marked, *Templa exornantur* (the temples are adorned). Holly and ivy still remain in England the most esteemed Christmas evergreens, though at the two universities the windows of the college chapels are decked with laurel. It was an old English superstition that on Christmas eve the oxen were

always found on their knees, as in an attitude of devotion, and that after the change from old to new style they continued to do this only on the eve of old Christmas day. This was derived from a prevalent mediæval notion that an ox and an ass which were present at the nativity fell upon their knees in a suppliant posture, as appears from numerous prints and from the Latin poem of Sannazaro in the 16th century. It was an ancient tradition, alluded to by Shakespeare, that midnight spirits forsake the earth and go to their own confines at the crowing of the cock. The Christmas celebrations in England have lost their primitive boisterous character, the gambols and carols are nearly gone by, and family reunions and evergreen trimmings are nearly all that remain of the various rough merriments which used to mark the festival. The last memorable appointment of a lord of misrule was in 1627, when he had come to be denominated "a grand capitaine of mischief." The poems of Herrick contain many descriptions of old English Christmas celebrations.—In the United States, since the Puritans were at first stern opponents of Christmas pastimes, the day was for a long time less generally celebrated in New England than in the middle and southern states. It has been made a legal holiday in several of the states, and is usually observed by a religious service and by making presents, and not unfrequently by trimming houses and churches with evergreens, and by imitating the German custom of Christmas trees. Santa Claus (St. Nicholas), originally introduced by the Dutch settlers of New York, is the American representative of the German Knecht Rupert.

CHRISTMAS, or Noel-Fearn, Henry, an English clergyman and author, born in London in 1811, died there, March 10, 1868. He received the degree of A. M. at St. John's college, Cambridge, in 1837, entered into orders, and filled several curacies till 1841, when he became librarian and secretary of Sion college. In 1840-'43, and 1854-'8, he was editor of the "Church of England Quarterly Review;" in 1840-'43 of the "Churchman;" in 1845-'8 of the "British Churchman;" and in 1859-'60, of the "Literary Gazette." In 1854-'9 he was professor of English history and archæology in the royal society of literature. He was also secretary of the numismatic society, and made a valuable collection of coins which were subsequently sold for a large sum. Besides editing several antiquarian works, contributing to various periodicals, and making translations from the French, German, and Portuguese, he published "Universal Mythology," "Shores and Islands of the Mediterranean," "Christian Politics," "Preachers and Preaching," "Sin, its Causes and Consequences," "Cradle of the Twin Giants," and "Echoes of the Universe." He also compiled memoirs of the czar Nicholas, and of the sultan Abdul-Medjid.

CHRISTOPHE, Henri, king of Hayti, born Oct. 6, 1767, died by his own hand, Oct. 8, 1820.

The accounts of his youth are conflicting; according to some he was born in the island of Grenada; others say in St. Christopher, St. Croix, or Santo Domingo. The uprising of the blacks in Santo Domingo found him a slave in that island, and he distinguished himself by activity and boldness. His bravery commended him to the notice of Toussaint l'Ouverture, who gave him a commission as brigadier general, and employed him to quell an insurrection in the northern province of the island. Successful in this, he was appointed governor of the province, and when the French under Leclerc subjugated that part of the island, he and Dessalines were declared outlaws. When Toussaint was seized by the French, Christophe and Dessalines again headed an insurrection, and before the close of 1803 succeeded in driving the French from Hayti. During the brief administration of Dessalines Christophe was general-in-chief of the army, and at his death in 1806 was appointed president for life by an assembly convened at Cape Haytien. The people of the southern portion of the island, however, preferred Pétion, and soon after organized a republic of which he was appointed president. A civil war ensued between the two chiefs, which continued for 11 years. In 1811 Christophe, following the example of Napoleon, abolished the republican government, caused himself to be proclaimed king of Hayti under the title of Henri I., and organized a hereditary monarchy and nobility. He promulgated a code which, though based on the *Code Napoléon*, was not a servile copy, but was adapted to the wants of the people. Meantime the defection of some of his adherents roused the jealousy and cruelty which seemed inherent in his nature, and did much to alienate the affections of his people. In general, however, his measures were judicious, but the mild and pacific sway of Pétion, and his successor Boyer, was far more agreeable to the negroes than the stern rule of Christophe. The number and activity of the malecontents increased, till finally the army became infected, and even the king's body guard went over to Boyer. Irritated at this, and determined not to be made a prisoner, he shot himself. His eldest son, Ferdinand, had been sent as a hostage to France by Gen. Leclerc, and died there in a hospital. His second son, Jacques Victor Henri, was killed by the insurgents a few days after his father's death. A pension was conferred on the widow of Christophe, but the enmity of the people caused her to leave the island. She went to England, travelled in Germany and Italy, and finally took up her abode in Pisa with one of her daughters.

CHRISTOPHER, duke of Würtemberg, a Protestant prince of the 16th century, born May 12, 1515, died Dec. 28, 1568. At the time of his birth the duchy of his father Ulric was in a very unsettled condition. In a little more than four years the confederated Swabian cities expelled Ulric from his principality, transferred

the dukedom to the house of Austria, and removed Christopher to Vienna. When Solyman besieged that city in 1529, Christopher was well nigh made a Turkish prisoner. But Charles V., fearing him more than his father, resolved to shut him up in a monastery, and for this purpose ordered him in 1532 to Spain. Christopher, finding an opportunity to escape, fled to Bavaria, where his uncle, the reigning duke, together with the landgrave of Hesse, took up his cause and that of his father; and entreaty proving unsuccessful, recourse was had to arms, which, through the secret aid of the French king Francis I., and a sudden sortie on the Austrians at Laufen, May 13, 1534, resulted in the restoration of Ulric to his duchy. Christopher succeeded to the dukedom on the death of his father in 1550, and set himself about establishing the reformed religion in his province. Instead, however, of seizing the church property, and devoting it to his own use, or dividing it among his nobles, like many Protestant princes of his day, he constituted of it a fund called the "Württemberg church property," out of the proceeds of which were supported all the public schools of the duchy, the university of Tübingen, and a variety of other public establishments. The duke also enlarged the liberties of the people and gave them a code of laws.—See Pfister's *Herzog Christoph* (Tübingen, 1819).

CHRISTOPHER, Saint, a martyr of the early church, beheaded, according to tradition, in the year 250, during the persecution of Decius. His feast is celebrated by the Greek church on May 9, and by the Latin church on July 25. The Mozarabic breviary, attributed to St. Isidore, states that a great portion of his remains were brought from the East to Toledo. Compostela, Valencia, and Astorga pride themselves on the possession of a part of his relics. The abbatial church of St. Denis, near Paris, also boasted of a like privilege. A man of gigantic stature and noble birth, he was baptized by Babylas, bishop of Antioch, and going into the desert, fixed his abode near a rapid stream, over which he was wont to carry travellers on his back. One day a little child called to him from across the swollen flood, and the hermit went fearlessly into the waters, and in the child whom he carried across discovered the Saviour. Hence his name of Christophoros, or Christ-bearer. Baronius and other historians regard him and his life as an allegory; the Bollandists and Baillet maintain the fact of his existence and his martyrdom.

CHRISTOPULOS, Athanasios, a modern Greek poet, born at Castoria in Macedonia in May, 1772, died in Wallachia, Jan. 29, 1847. His father, a Greek priest, removed from Macedonia to Bucharest in Wallachia while his son was yet a child. Athanasios was well educated at Buda in Hungary, where he learned Latin, and at Padua in Italy, where he studied medicine. On his return to Bucharest he was appointed tutor to the children of the prince

of Wallachia, Alexander Murusi, who on being transferred to Moldavia took Christopulos with him and employed him in various public offices. His first publication was a drama entitled "Achilles," which, after having been played successfully at Jassy and at Bucharest, was printed at Vienna in 1805. In the same year he published a grammar of modern Greek. Murusi being recalled to Constantinople, Christopulos accompanied him thither, and during his residence in that city wrote in modern Greek his love songs and drinking songs, on which his reputation chiefly rests. Prince Caradja, who was now appointed hospodar of both principalities, took Christopulos with him to Moldavia, where he gave him official position and charged him with the compilation of a code of laws for Wallachia, a task which occupied him two years. After the fall of Prince Caradja Christopulos resided some time at Hermannstadt in Transylvania, occupied mainly with political and philosophical writings. He went thence to Greece, and in 1836 returned to Wallachia, where he spent his remaining years in literary labor. He translated the first book of the Iliad into modern Greek, and also the first two books of Herodotus. His lyric poems were published at Vienna in 1811, and a new and enlarged edition appeared in 1821. They were published also at Paris in 1833, with a French translation, and with some of his prose writings (2 vols. 8vo). A later and fuller edition appeared at Paris in 1841. A collection of his writings was published at Athens in 1853 under the title *Ἑλληνικὰ ἀρχαιολογῆματα*. His lyric poems are exceedingly popular among the Greeks.

CHRIST'S HOSPITAL, commonly called the Blue Coat school, one of the oldest and most famous of the charitable educational establishments of London. It was founded in 1552, by the citizens assembling a number of poor children for education and maintenance. Edward VI. favored the plan, and by charter, dated June 26, 1553, 10 days before his death, incorporated the three hospitals of Christ for poor fatherless children and foundlings, Bridewell, and St. Thomas the Apostle, vesting lands for their support in the mayor, commonalty, and citizens. Five years afterward Christ's hospital was opened, under the charter, in the building in Newgate street belonging to the recently suppressed brotherhood of gray friars. Four hundred children were entered. On entering they were clothed in russet, which was subsequently changed to the costume they now wear, namely, a blue tunic reaching to the feet, bright yellow petticoat and yellow stockings, red leathern girdle, clerical band around the neck, and a little round cap of black woolen. Charles II. granted £1,000 for seven years to found a mathematical school for 40 "king's boys," and an annuity of £370 10s. to send 10 others to sea; 14 additional pupils in mathematics were added on other foundations, and a writing school in 1694, by Sir John Moore,

lord mayor. The course of study was gradually augmented, until at present it embraces all the branches of a sound elementary education. The main establishment at London has four classical masters, two writing masters, two ushers, and mathematical, drawing, and singing masters, with about 800 scholars. In 1683 a branch hospital for preparatory training was established at Hertford, which now has a classical master, a writing master, two ushers, two female teachers for the girls' department, 400 boys, and 70 girls. The domestic economy of the hospital is on a plain but comfortable scale, from which, however, many of the peculiarities of old times have but recently disappeared. Formerly the scholars performed all the menial duties of the establishment, but now they are required merely to make their own beds. Until 1824 the boys breakfasted on bread and beer, and till more recently ate from wooden trenchers and drew their beer from leathern blackjacks. Every Easter they visited the exchange and the lord mayor.

Christ's Hospital.

The "king's boys" were formerly presented at court once a year; and even now from Quinquagesima Sunday to Good Friday the hospital is visited by the public to witness the "suppings in public." The government of the hospital is vested in the lord mayor and aldermen of London, and in contributors of £500. Governors exercise the right of presentation to the hospital, and have also the patronage of some ecclesiastical benefices. The hospital has long since ceased to be a "charity," properly so called, most of the pupils now admitted being children of freemen of the city of London and of clergymen of the church of England. Children whose parents have an income of £300 a year cannot be lawfully admitted. No pupil is admitted under the age of 7, nor can he remain after 15, mathematical and Greek scholars excepted. The total income is about £40,000, and the expenditures about the same. The buildings of the hospital were mostly destroyed by the great fire in 1666, but were rebuilt under the direction of Sir

Christopher Wren. They were repaired and partially rebuilt in 1825-'9. Excepting the new hall, which is one of the ornaments of the city, the buildings are irregular, although not inconvenient. Portraits of many historical personages, patrons of the institution, are preserved in its apartments. Among the eminent men educated at Christ's hospital are Bishop Stillingfleet, Camden the historian, Richardson the novelist, Coleridge, Lamb, and Leigh Hunt.

CHROMATICS, that branch of optics which treats of the mathematical relations of colors. White light may be compared to a full chord in music, containing all the notes in the octave, but the comparison must not be insisted on too closely. By refraction through a prism, the colors may be separated more or less perfectly. This separation of colors by refraction takes place in nature by means of rain drops, producing the parti-colored rainbow, or by means of minute snow crystals, producing halos. By experiment, refraction can be produced in a great variety of ways, and the different colors of white light can also be brought out by other means than refraction. The mean distance between two waves in a ray of light is $\cdot 0000225$ of an inch; in violet-colored rays, $\cdot 0000167$; and in red rays, $\cdot 0000266$. To chromatics also belongs the discussion of the phenomena of polarization and double refraction. These phenomena depend upon the form of the wave of light, and the direction of the motion in that wave, the wave itself always going in a straight line. It is in these most minute and subtle optical investigations that the undulatory theory of light has proved most fruitful.

CHROMIUM (Gr. *χρῶμα*, color), a metal so named from its tendency to impart beautiful colors to its compounds. About the year 1760 S. Lehmann, a Saxon mineralogist, was puzzled by a red mineral that was thought to contain gypsum, iron, and lead, and which was called red-lead spar. He wrote about it to Buffon in Latin, *De nova Mineralis Plumbi Specie Crystallina rubra*; but no one could tell him what it was. Each successive chemist who examined it detected something new, and the ore was in a fair way of contributing a complete mineralogical cabinet in itself, until Klaproth announced that it contained a new metal, and Vauquelin discovered in it a new acid. As soon as these two discoveries were announced, many of the chemists of the day attacked the mineral; and it was not long before they found that it was composed of chromate of lead. Here the history of this element would have come to an end, if some years later an iron ore had not been discovered in France which also contained it, and thus afforded it in sufficient quantity for the various uses to which it was destined to be applied. Chromium ore has since been found in many localities, among others in the United States near Baltimore, where it is a source of profit to the owners of the mines. Deville obtained chromium in the fused state by igniting a mixture of chromic

oxide and sugar charcoal in a lime crucible, intensely heated in a portable blast furnace. The metal thus prepared is shining, has a steel-gray color, a specific gravity of 6, and is hard enough to scratch glass. J. Loughlin prepares metallic chromium by exposing a mixture of chromic oxide and potassium cyanide to a white heat in a covered porcelain crucible. A solution of chromic chloride or other chromic salt, treated with sodium amalgam, yields an amalgam of chromium, which, when heated in a stream of hydrogen, leaves metallic chromium in the form of a pulverulent sponge.—Chromium forms four well marked oxides: a protoxide, CrO , and a sesquioxide, Cr_2O_3 , both capable of forming salts with acids; an intermediate oxide, CrO , Cr_2O_3 , corresponding to the magnetic oxide of iron; and a stable anhydride, CrO_3 , which by its action on bases forms salts corresponding to the manganates and ferrates. It also appears probable that a perchromic acid, HCrO_4 , exists; at least a blue liquid, which is soluble in ether, is obtained on pouring peroxide of hydrogen into a solution of chromic acid; but none of its compounds are known. The protoxide is known only in the hydrated condition, when it has a dark brown color. It forms a double sulphate with sulphate of potassium, CrSO_4 , $\text{K}_2\text{SO}_4 + 6\text{H}_2\text{O}$, corresponding to the double sulphate of iron and potassium both in form and composition. The crystals are of a fine blue color. Sesquioxide of chromium is obtained as a grayish green hydrate, by boiling with alcohol a solution of bichromate of potassium, acidulated with sulphuric acid. On the addition of ammonia, a bulky, gelatinous, bluish green precipitate of the hydrated oxide is produced. In this form it is freely soluble in acids, and forms salts, the solutions of which are green, but they do not crystallize. Sesquioxide of chromium gives rise to another set of soluble salts, which are of a violet color, and crystallize readily.—Besides the soluble variety of the salts of chromium, an anhydrous, insoluble series is known, corresponding, it would seem, to the dense and comparatively inert modification of the metal itself. Anhydrous green oxide of chromium is not decomposed by heat, and hence is used as a green color in enamel painting. For this purpose it is usually prepared by decomposing basic chromate of mercury at a red heat. Sesquioxide of chromium is the coloring ingredient in greenstone, in the emerald, in pyrope, and in several other minerals. The pink color used on earthenware is prepared by heating to redness a mixture of 30 parts of peroxide of tin, 10 of chalk, and 1 of chromate of potassium; the product is then powdered and washed with weak hydrochloric acid. A beautiful green pigment, known as *vert de Guignet*, is made by calcining bichromate of potassium with three times its weight of crystallized boracic acid.—Chrome ironstone, FeO , Cr_2O_3 , is the principal ore of chromium. It corresponds in composition to the brown oxide of chromium,

and to the magnetic oxide of iron; part of the iron is, however, generally displaced by the isomorphous metal magnesium, and part of the chromium by aluminum. Of the pure ore, 100 parts contain 48.27 per cent. of chromium, and yield 39.6 of chromic acid.—Chromic anhydride, or chromic acid, CrO_3 , is obtained by mixing four measures of a cold saturated solution of bichromate of potassium with five of oil of vitriol; as the liquid cools the chromic anhydride separates in beautiful crimson needles. The crystals are allowed to dry on a porous tile under a bell glass. It fuses at 400° , and at a higher heat is converted into the sesquioxide. The anhydride is deliquescent, has a sour metallic taste, and possesses considerable oxidizing power.—*Chromates*. Chromic acid forms three classes of salts: basic, normal, and acid. Bichromate of potash, or anhydro-chromate of potassium, $\text{K}_2\text{Cr}_2\text{O}_7 = \text{K}_2\text{O}$, 2CrO_3 , is prepared by heating chrome ironstone to redness and quenching in cold water; it is then reduced to an extremely fine powder, and heated to bright redness in a current of air, in a reverberatory furnace, with a mixture of chalk and carbonate of potassium, the mixture being constantly stirred to hasten the oxidation. When this is complete, the product is digested in water, carbonate of potassium being added if necessary to decompose any chromate of calcium which may have been formed, and the yellow solution is drawn off from the insoluble matter; it is then supersaturated with nitric acid; a portion of silica is thus precipitated, and after this has been separated, the liquid on evaporation yields crystals of the bichromate of potash. Neutral chromate of potash, K_2CrO_4 , is prepared by adding a solution of carbonate of potassium to the bichromate, until it becomes of a light yellow color. A terechromate of potassium, K_2O , 3CrO_3 , has also been obtained by Mitscherlich. Chromate of lead, PbCrO_4 , forms a pigment called chrome yellow. It is obtained by precipitating a somewhat dilute solution of acetate of lead by one of chromate or bichromate of potash. It is insoluble in water or acids. At 400° to 500° its color becomes reddish brown; at a higher temperature it fuses. The fused chromate is sometimes used instead of oxide of copper in organic analysis. Dibasic chromate of lead, of a splendid scarlet color, may be obtained by boiling a solution of the yellow chromate of lead with half an equivalent of lime; or by adding to a solution of nitrate of lead a solution of chromate of potassium, with which an additional equivalent of hydrate of potash has been previously mixed. A still more brilliant color may be obtained by fusing 1 part of normal chromate of lead with 5 parts of nitre. This salt is used to impart a permanent orange to calico.—*Sulphates of chromium*, Cr_2SO_4 . There are three varieties of this salt, the first green, the second violet, and the third red. The violet modification forms with sulphate of potassium, and with sulphate of ammonium, a beautiful violet double salt

(chrome alum), which crystallizes by spontaneous evaporation in bold octahedra, and corresponds in form and composition to ordinary alum.—The following are the most important applications of chromium compounds in the arts. The yellow or neutral chromate of potash is the basis of all other preparations, being made directly from the chrome ironstone. The red or bichromate of potash is obtained from the foregoing salt, and is extensively employed in the arts. In photography it is the basis of most of the printing processes, on account of its property of rendering gelatine insoluble by exposure to light. In dyeing, it is extensively used as a mordant. It is the material from which the chromic oxide, chromic acid, and the metallic chromates are prepared. Chromic oxide is the most insoluble green pigment known; it is extensively used in printing bank notes and in staining glass and painting porcelain. Chromic acid is a powerful oxidizing agent, and is used on this account in chemical researches; is found very valuable as an exciting fluid in galvanic batteries; was used for preparing the beautiful mauve red from aniline; is employed in bleaching palm oil, and in destroying the emphyreumatic impurities of acetic acid, &c. The chromates of lead, bismuth, baryta, strontia, and zinc are employed as pigments, varying in tint from the vermilion red of the basic chromate of lead to the pale straw yellow of the strontia salt. The common chrome green is a mixture of chromate of lead and Prussian blue. The beautiful violet chromic chloride has been proposed as a remedy for cancer. Chromium steel, made by combining about 5 per cent. of chromium with cast iron, possesses most remarkable properties. On account of its excessive hardness, it is the best metal for the construction of safes, while its tensile strength, equal to a strain of 140,000 lbs. to the square inch, especially adapts it to the construction of suspension bridges.

CHRONICLES, the name first given by Jerome to two books of the Old Testament, which in the English Bible are the last of the historical books, while in the Hebrew Scripture they conclude the entire volume. By the Alexandrine translators they were termed *Paraleipomena*, or things omitted, being regarded as supplementary to the previous histories. In the original Hebrew they are entitled "Words of the Days" (*Dibre hayamim*), and form, as their internal character demonstrates, but one book. The Chronicles open with genealogical registers of ancient and renowned families or races; they then narrate the history of David, harmonizing with the earlier account in the book of Samuel; then follows a history of Solomon, and of the increasing prosperity and glory of the Jews under him; after the division of the kingdom at his death, they trace the history of Judah, the more powerful branch, and continue the narrative till after the fall of Israel, and to the end of the exile in Babylon. They thus had a com-

paratively late origin, which is indicated also by the style and idiom, and by the Levitical coloring which overspreads much of the narrative. The Jewish and Christian traditions, from the earliest times down to the 17th century, have referred the Chronicles to the age and to the pen of Ezra. Spinoza assigned their origin to the time of the Maccabees, and his opinion has been accepted by several later scholars. Bertheau, one of the ablest writers on this book, believes it was written about 300 B. C. The earlier Jewish records furnished the materials of the history in the Chronicles, and numerous books are mentioned as sources and authorities which are not extant, or have not been admitted into the canon. The chief source appears to have been a "Book of the Kings of Judah and Israel," which however cannot have been our canonical book of Kings. The design of the book seems to have been, by a review of the history of the theocracy, to prove that Levitical worship had been maintained and favored by all pious kings, and that adherence to it or departure from it had been the condition of fortune or misfortune to the Jewish people. The discrepancies between the books of Chronicles and of Kings have occasioned an important discussion on the trustworthiness of the history of the former. Prominent among those who have denied to the accounts peculiar to the book of Chronicles any claim to credibility are De Wette, *Beiträge zur Einleitung ins Alte Testament* (1806), and Gramberg, *Die Chronik nach ihren geschichtlichen Character und ihrer Glaubwürdigkeit neu geprüft* (1823). Among the most successful writers in vindication of the Chronicles are Movers (*Kritische Untersuchungen über die Biblische Chronik*, Berlin, 1833) and Keil (*Apologetischer Versuch über die Chronik*, Berlin, 1833). Of more recent commentaries, the most valuable is that of Bertheau, *Die Bücher der Chronik erklärt* (Leipsic, 1854; 2d ed., 1860; English, Edinburgh, 1857). See also the introductions to the Old Testament by Hävernick, Davidson, and Bleek, and Ewald's *Geschichte des Volkes Israel*.

CHRONOLOGY (Gr. *χρονολογία*, from *χρόνος*, time, and *λόγος*, discourse), the science of establishing historical dates, by arranging events in the order of their succession, and determining the interval between each and some fixed period in time. We are so accustomed to the facility with which this is accomplished by means of the Gregorian calendar and the conventional fixed point of the Christian era, that we can hardly appreciate the obstacles which have been overcome in order to bring the science to its present state. It was necessary at the outset to find some tangible standard by which to measure the intangible element of time. The most obvious measure is the day, or regular interval between one apparent rising or setting of the sun and another. This, though exact as far as we can know, is so short as to be inconvenient when applied to

long periods. The next longer obvious measure is the interval between one new moon and another. It was found that this was about $29\frac{1}{2}$ days; and the month became the usual standard for measuring considerable spaces of time. But a larger definite measure was desirable for still longer periods. The round of the seasons appeared to furnish this; but, ignorant of the cause, men had no means of ascertaining the precise length of the year, or indeed if it had any certain length. Twelve months was an approximation to the average interval from harvest to harvest, and the year was at first made to consist of 12 months, alternately of 29 and 30 days, or 354 days. This being found too short, the year was lengthened to 360, and then to 365 days, various expedients being adopted to make the lunar and solar years correspond, by intercalating the requisite number of days. In time it was found that a fractional part of a day was required to make up a complete year. By observing the interval between the periods when Sirius, the dog star, rose with the sun, the value of this fraction was found to be very nearly one fourth of a day. The year of $365\frac{1}{4}$ days was called the Sothic year, from the Egyptian name for Sirius, and sometimes the square or perfect year. It differs by less than 12 minutes from the true year as settled by the most accurate observations. Though known to astronomers long before, it appears not to have been used for chronological dates until the time of Julius Cæsar. The old years of 354, 360, and 365 days were still employed for various purposes, and the commencement of the year was made to fall at different seasons. Hence has arisen much of the confusion which exists in the calendars of different times and nations. (See CALENDAR, DAY, and YEAR.)—For a long period there was no fixed point of time from which dates were reckoned. Individuals would naturally count from the year of their birth; monarchs from that of their accession, which is the notation of most ancient inscriptions. In course of time different peoples began to date from some event of national importance. The earliest of these fixed epochs is that of the Romans, who some centuries after that event began to date from the foundation of Rome. There was some question as to the exact time of this, some placing it in the year answering to our 753 B. C., others in 751, 750, or 747. In Greece, the Olympic games became the event of paramount national interest. These games were celebrated every fourth year. But in retracing the succession of these Olympiads, when, perhaps in the 3d century B. C., it was deemed advisable to adopt them as an era, the victory of Coræbus was found to be the earliest recorded. Consequently the period of the games in which he was victorious was called the first Olympiad, and they were calculated to have taken place about 108 years after the restoration of the games by Iphitus, or about 776 B. C. An event occurring 775 years after

the commencement of this era was set down as happening in the 3d year of the 193d Olympiad. Moreover, the original Grecian year consisted of 12 months of 29 and 30 days alternately; and in order to make the lunar year accord with the solar, an intercalary month of 30 days was added, at first every second year, and subsequently three times in eight years. This period of eight years, styled the *octaeteris*, contained 99 months, or 2,922 days, exactly equal to 8 years of $365\frac{1}{4}$ days, the Olympiads consisting alternately of 49 and 50 months. The three years (the 3d, 5th, and 8th) which had the intercalary month were styled embolismic years, and had 384 days, while the other five years had 354 each. But as a lunar month is somewhat more than $29\frac{1}{2}$ days, the *octaeteris* fell a little short of 99 months; and to make up for this, three days were added to each alternate Olympiad; but this made the solar year by so much too long. The error was allowed to go on for 40 Olympiads, by which time it had accumulated to 30 days, when a month was dropped, and the solar and lunar years again corresponded. Thus in a period of 40 Olympiads there were four kinds of years: the common, of 354 days; the embolismic, of 384; the last of each alternate *octaeteris*, 387; and the last year of the 40th Olympiad, of 357 days. In the last year of the 86th Olympiad was introduced the Metonic cycle of 19 years, perhaps the greatest achievement of ancient astronomy, at the end of which each new moon comes back to the same day of the year. This continued in use as long as time was reckoned by Olympiads, and is still used in determining the days upon which the movable feasts of the church will fall. The Babylonian era of Nabonassar, beginning at noon, Feb. 26, 747 B. C., has a special scientific interest from the fact that its commencement is astronomically determined to a minute. The year consisted of 12 months of 30 days each, to which 5 days were added at the end, so that 1,460 Julian years are equal to 1,461 Babylonian. The Mohammedans, the Persians excepted, reckon from the *hegira*, or flight of Mohammed from Mecca to Medina, July 16, A. D. 622. The Mohammedan year is strictly lunar, the civil months being adapted to the lunations by means of a cycle of 30 years, 19 of which have 354 days, and 11 have 355. Hence 30 Mohammedan years are equal to only 29 Julian years and 39 days. To convert a date of the *hegira* into the corresponding one of our notation, it is not sufficient to add 622, as is sometimes carelessly done. Thus the treaty between the emperor Charles VI. and the sultan is dated 1153 of the *hegira*; instead of 1775 of our era, it is 1740. The difference increases nearly one year in 30. Since about 1530 the Mohammedans in India have dated from the *hegira*, but they use the solar year; hence their dates are now about nine years behind the Arabic and Turkish. The Persians do not date from the *hegira*, but from A. D. 632, the year of the accession of the

shah Yezdegird; their year consists of 365 days, and they have a complicated but very accurate system of intercalation. This era is also used by the Parsees of India. The Armenians date from July 9, 552, the year of the council of Tiben, which, by condemning the decrees of the council of Chalcedon, formally separated the Armenian from the Greek church. The Hindoos use both the sidereal and the solar year, and employ the eras of Kaliyug, 3101 B. C., the Vicramaditya, 56 B. C., the Salivahana, A. D. 78, and the Fuslee, about A. D. 590. The Chinese have a complicated calendar. For chronological purposes they employ a series of yearly, monthly, and daily cycles of 60. Each year, month, and day has its own name in its cycle. By compounding these names, a single word expresses the year, month, and day. The year 1864 was the first of a cycle, so that 1873 is its 10th year. The character denoting a cycle first appears at 2357 B. C., and this is noted as the 41st year of the cycle, so that the epoch of this cycle would be 2397 B. C., which is accepted by the authors of the *Art de vérifier les dates*; but the Chinese mathematical tribunal has from time immemorial begun this cycle with 2277 B. C., apparently assuming that there had been a dating back in the records. For more than 20 centuries Chinese historians have dated from the year of the accession of the reigning emperor. A particular name, not necessarily that of the sovereign, is given by authority to each reign, and the years are numbered 1, 2, 3, and so on; a register of these eras is kept, by aid of which the chronological year may be ascertained; just as to determine the date of an English statute, we must know the year in which the sovereign under whom it was enacted began to reign. The Jews, whose calendar is that of the ancient Greeks in its perfected form, date from the creation, which according to their usual computation took place in 3760 B. C. The Russians date ecclesiastically from the creation, which, according to their computation of the dates in the Septuagint, took place 5508 B. C. Historically they use the common Christian era, but adhere to the old style of 365 $\frac{1}{4}$ days to the year, which is nearly 12 minutes too long, the difference amounting to not quite a day in a century. In 1700 the variation was 11 days, in 1800 it became 12, and will so continue till 1900, when it will be 13, and will remain so until 2100, when it will be 14, should the Russians then adhere to the old style.—When Christianity became predominant in the civilized world, writers began to date from various epochs in the history of the Saviour. About the middle of the 6th century Dionysius Exiguus, a Roman abbot of Scythian birth, introduced the method of dating from the birth of Christ, which according to his computation took place in the 4th year of the 194th Olympiad, the 753d from the foundation of Rome. It is generally conceded that he placed this event about four years too late; this is however of no im-

portance in chronology, as it merely involves the necessity of placing the date of the birth in the year 4 B. C. Dionysius began his year with the Annunciation, the 25th of March, nine months before the day which is now considered to be that of the birth of Christ; so that his era, which continued in use for some centuries, is by so much in advance of that now in use. Christmas and Easter were also sometimes taken as the commencement of the year. These differences occasion some apparent discrepancies in dates during the middle ages. Thus, Charlemagne was crowned on Christmas day, 800, and died Jan. 28, 814, reckoning the year to begin on the 1st of January. But the chronicle of Metz says that he was crowned on Christmas day, 801, and the chronicle of Moissac that he died in January, 813. Although there is an apparent variation of two years, the same day is meant in every case. The Metz chronicle begins the year with Christmas day, so that the remaining days of December belong to 801; the Moissac chronicle begins the year with the annunciation, and the days from Jan. 1 to March 25 belong to 813. Had the coronation taken place a week and the death two months later, the dates by all these modes of reckoning would have been the same. So, too, in all dates previous to 1582, it must be noted whether they are given in the old style or have been reduced to the new, as is usually done in modern chronology.—Could the precise time of the creation be ascertained, it would be the natural starting point from which to date. But the history of ancient nations, unless we make an exception in the case of the Hebrews, goes back into mythical periods of thousands or millions of years; and even after the records begin to assume a historical aspect, the discrepancies are very great. The Hindoo chronology, as computed by Gentil, reaches to 6,174 years before the Christian era; the Babylonian to 6,158, and the Chinese to 6,157, according to Bailly. About 200 different computations have been made, based upon the Hebrew, Septuagint, and Samaritan texts of the Bible. The longest is one by Regiomontanus, 6,984 years; next that of Clement of Alexandria, 5,624; the most accredited one based on the Septuagint is 5,508; that by Usher, from the Hebrew, is 4,004, which the Jews reduce still further, the lowest, by Rabbi Lipmann, being only 3,616 years. The main cause of these discrepancies is the different numbers given in the Septuagint and the Hebrew texts. There is a Samaritan text of the Pentateuch which differs from both; but this is now admitted to be of no authority. Josephus also gives dates, but he is altogether too careless to be taken into account. The main variations between the Septuagint and the Hebrew are found in the two periods from Adam to the flood, and from the flood to the call of Abraham. For the former period both give the same list of 10 generations in direct succession, with the entire life of each patriarch, in which they agree; and his age at the

birth of the son by whom the succession was carried on, which gives the total length of the period, wherein they differ widely. The two statements stand thus:

PATRIARCHS.	BEFORE BIRTH OF HEIR.		Total Age in both.
	Hebrew.	Septuagint.	
	Adam.....	130	
Seth.....	105	205	912
Enos.....	90	190	905
Cainan.....	70	170	910
Mahaleel.....	65	165	895
Jared.....	162	162	962
Enoch.....	65	165	865
Methuselah.....	187	187	969
Lamech.....	182	183	777*
Noah (at flood).....	600	600	
Time of the flood.....	1,656	2,262	

There are various means of explaining this difference of 606 years. Modern scholars give the preference to the following of Böckh. The 2,262 years of the Septuagint are considered an attempt on the part of the 70 interpreters at reducing the 1,656 years of the Hebrew text to 19 Sothic cycles, which are equal to 27,759 Egyptian years, or to as many months of 29½ days, in all 818,890½ days, and which are equal to 2,242 Julian or Sothic years. This Sothic year, which differs from the Julian in the day of commencement alone, seems to have been the year of the priests, and its early use by the Egyptians is shown on a calendar sculptured on the exterior of the temple of Medinet Abu at Thebes. But supposing the Hebrew figures proved genuine, there remains the difficulty of proving them historical. They place the time of the flood at about 2340 B. C. Both the Babylonian and Egyptian histories represent powerful monarchies as existing about or before that date. Sir Gardner Wilkinson places the beginning of the 4th Egyptian dynasty at 2450, and this was preceded by several others. Rawlinson places the foundation of the Chaldean monarchy at about 2286. Others carry these dates still further back. This difficulty may indeed be got over by assuming the Egyptian and Babylonian chronologies to be erroneous. But the Hebrew dates seem to be inconsistent with historical events narrated in connection with them. According to the present text, Abraham was born not quite 300 years after the flood, when the whole human family consisted of but eight individuals. Yet it is clear from the narrative that in his day the whole region from the Euphrates to the Nile was densely peopled. There were also powerful kingdoms east of the Euphrates; for we find Chedor-laomer, king of Elam, that is, of southern Persia, with three allies, making military expeditions to the valley of the Jordan. Now a period of about 376 years from the flood to the migration of Abraham to Canaan is altogether too short to allow such an increase of the human race, ac-

ording to any known law of the growth of population. If we assume the Septuagint period of 1,147 years, this difficulty is obviated, and the chronology approximates to that of the Egyptians, Babylonians, and Chinese. It is safer, upon the whole, to consider the entire chronology of the world to be uncertain up to about the time of Abraham. From that time the chronologist begins to tread upon firm ground, the Hebrew dates being clear and definite within a few years. The exodus from Egypt is well fixed at 440 years after the migration of Abraham. From the exodus to the completion of Solomon's temple the Hebrew text gives 480 years, the Septuagint 440. An attempt has indeed been made to extend this period by about 150 years; but it seems to be based upon insufficient data. From the time of Solomon Hebrew chronology becomes fairly connected with that of Egypt, Assyria, and Babylonia, and the dates of each are confirmed by the others. Chinese and Hindoo chronology is fairly credible to about 2200 B. C. Greek and Roman dates are generally well authenticated to the 1st Olympiad and the establishment of the consulate, previous to which they are mainly traditional or legendary. From the Christian era to our own times the date of nearly every important event is settled beyond question within a year or two.—The materials for the chronologist consist of original monuments, such as inscriptions, coins, and the papyri found on Egyptian mummies, and of written records either contemporaneous with the events or handed down through a succession of writers. Inscriptions and coins have a special value, as they are usually made by public authority, and in any case exist in their original state; whereas in successive transcriptions or quotations there is always a possibility of error. The Assyrian, Babylonian, and Egyptian inscriptions are in extinct languages and in characters long obsolete. For the means by which these have been deciphered, see CUNEIFORM INSCRIPTIONS, and HIEROGLYPHICS. The written records of Egypt, besides the papyri, come through Manetho, who lived about 300 B. C., and professes to have made use of original authorities. Of his work we have only fragments preserved in citations by later Greek writers. The written history of Babylonia, besides the inscriptions and tablets, comes mainly through Berosus, who wrote about 260 B. C.; of his work also only fragments are extant. Ctesias, a Greek, about 415 B. C., wrote a history of Babylonia, but it is not regarded as authentic. Herodotus is valuable only as to events of his own time, about 450 B. C., and those of a century or two earlier.—Attempts have been made to bring astronomy to the aid of chronology. Eclipses being anciently regarded as portents, occasional mention is made of them in connection with historical events. Thus Herodotus says that a battle between the Medes and Lydians was brought to a close by a total eclipse of the sun, assumed to be that of 610 B. C. Now if it

* So in the Hebrew; in the Septuagint, 753.

could be ascertained by astronomical calculation that an eclipse was visible about that time in Asia Minor, its exact period would fix the date of the battle. But the calculation of a solar eclipse at such a remote time is a somewhat uncertain operation; for the minutest error in the tables used would throw the moon's shadow on an entirely different part of the globe. Mr. Airy, the British astronomer royal, has calculated that the eclipse of 610 could not have been visible in any part of Asia Minor, and that the only one applicable to the case is that of May 28, 585. If therefore the statement of the historian as to the fact, and the calculation of the astronomer as to the eclipse, are correct, the battle occurred in 585 and not in 610. Either may be erroneous, most likely Herodotus. Lunar eclipses, being visible over a whole hemisphere, require much less nicety of calculation, and are more available for chronological purposes.—The foundation of the modern science of chronology may be said to have been laid by Joseph Scaliger in his works *De Emendatione Temporum* (Paris, 1583; enlarged, Leyden, 1598; Geneva, 1629), and *Thesaurus Temporum* (Paris, 1606; best ed., Amsterdam, 1658). Among other important works are: Petavius, *De Doctrina Temporum* (Paris, 1627), with its continuation, *Uranologion* (Paris, 1630), and abridgment, *Rationarium Temporum* (Paris, 1630, and since); Riccioli, *Chronologia Reformata* (Bologna, 1669); *L'Art de vérifier les dates*, by the Benedictines of St. Maur (last ed., 1783-'7), continued by Fortia d'Urban; Champollion-Figeac, *Résumé complet de chronologie générale et spéciale* (Paris, 1830); Ch. Dreyss, *Chronologie universelle* (1853); Kornick, *System der Zeitrechnung in chronologischen Tabellen* (Berlin, 1825); Ideler, *Handbuch der mathematischen und technischen Chronologie* (Berlin, 1825), and *Lehrbuch der Chronologie* (Berlin, 1831); Matzka, *Chronologie in ihrem ganzen Umfang* (Vienna, 1844); Lepsius, *Chronologie der Aegypten* (Berlin, 1849); Archbishop Usher, *Annales Veteris et Novi Testamenti* (London, 1650-'54); Sir Isaac Newton, "Chronology of Ancient Kingdoms" (London, 1728; an answer to it was written by Fréret, Paris, 1758); Jackson, "Chronological Antiquities" (London, 1752); Blair, "Chronology and History of the World" (London, 1756; a new edition, revised and enlarged by J. W. Rosse, was published in London, 1856); Playfair, "System of Chronology" (Edinburgh, 1784); Hales, "New Analysis of Chronology" (1800-'12); Clinton, *Fasti Hellenici* (Oxford, 1824-'34), and *Fasti Romani* (Oxford, 1845-'50); Sir Harris Nicolas, "The Chronology of History" (in Lardner's "Cabinet Cyclopædia," vol. xlv., 1833). Rawlinson's translation of Herodotus (4 vols., London, 1858-'60; new ed., London, 1862, New York, 1872) is furnished with valuable dissertations in respect to ancient chronology by Sir Henry Rawlinson and Sir Gardner Wilkinson; and

his "Five Great Monarchies" (2d ed., London, 1870; New York, 1871) treats elaborately of the chronology of Chaldea, Assyria, Babylon, Media, and Persia. Among the most useful manuals of reference are: J. W. Rosse, "Index of Dates" (London, 1858), which forms an alphabetical index to Blair's "Chronological Tables;" Haydn's "Dictionary of Dates," continued by Vincent (12th ed., London and New York, 1866, with supplement to 1870); Woodward and Cates's "Encyclopædia of Chronology" (London, 1872).

CHRONOMETER. See CLOCKS AND WATCHES.

CHRUDIM, a town of Bohemia, formerly capital of a circle of the same name, situated on the right bank of the Chrudimka, 60 m. E. S. E. of Prague; pop. in 1869, 11,218. It has a *Realschule*, a high school, several breweries, sugar factories, and paper mills.

CHRYSALIS, a name generally limited to the second stage of the growth of lepidopterous insects, or to the pupa from a caterpillar, be-

Chrysalis of large Tortoise-shell Butterfly, magnified. 1. With the upper parts opened. 2. With the upper parts pressed down and adhering to the body.

cause, as the term implies, they are sometimes gilt or ornamented with golden spots; aurelia is synonymous with chrysalis. When the limbs are not covered, the term nymph is applied to insects in this stage, more especially when the grubs eat; and the word pupa is properly employed for those which entirely lose the larva form, take no food, and remain motionless, bound up like a swathed mummy. The chrysalis, like all pupæ which undergo a complete metamorphosis, is motionless and does not eat. On a close examination, traces of the head and its organs, the wings, and the legs, may be seen closely pressed to the body and adherent to it by a kind of varnish. Some are angular and covered with protuberances, but most are smooth and spindle-shaped. The manner in which the perfect insects come out has been described in the article BUTTERFLY, where also are mentioned their various modes of suspension. Most are contained in a cocoon, from which exit is easy for the insect by the disposition of the threads at one end. Those of the butterflies are uncovered and

fixed by the posterior portion, and usually open in a few days, while in others the chrysalis state lasts through the winter, either in the open air, underground, in holes in walls and trees, or in silken cocoons. Some of the social caterpillars remain in company in the chrysalis state, each constructing a cocoon at the end of their last nest. The most useful of these cocoons is that of the silkworm; but other caterpillars form coverings more remarkable in shape and presupposing greater intelligence in the makers. As in the previous stages of the metamorphosis, the chrysalis opens on the back to give exit to the perfect insect.

CHRYSEÏS, daughter of Chryses, a Trojan priest of Apollo, mentioned in the Iliad. When Lyrnessus was taken by the Greeks, in the distribution of the spoils she fell to Agamemnon. On his refusal to give her up to her father, who offered a rich ransom, Apollo sent his arrows into the Grecian camp in answer to the prayers of his priest, spreading a pestilence among the soldiers. Agamemnon was then forced to surrender his captive, but to fill her place seized upon Briseis, who had fallen to Achilles. Hence arose the quarrel between these two warriors which prolonged the Trojan war, and with which the story of the Iliad opens.

CHRYSIPPUS, a Greek philosopher of the Stoic school, born at Soli, in Cilicia, in 280 B. C., died in 207. It appears that he went to Athens after having lost a large fortune, and became a pupil of the Stoic Cleanthes, perhaps of Zeno himself, but at the same time diligently studied the arguments of the Sceptics against the Stoic doctrines. His acuteness in argument obtained for him the designation of "the sword for the knots of academicians." In his philosophical system he followed closely in the steps of his master, whose doctrines he seems to have made popular. It is stated that he was the author of 700 works. Only a few fragments of them have been preserved. The most elaborate essays upon Chrysippus and his philosophy are those of Bagnet, *De Chrysippi Vita, Doctrina, et Reliquiis* (Louvain, 1822), and F. C. Petersen, *Philosophiæ Chrysippi Fundamenta* (Hamburg and Altona, 1827).

CHRYSOBERYL (Gr. χρυσός, gold, and βήρυλλος, beryl), a gem, also called cymophane (κύμα, wave, and φαίνω, to appear), so named from a peculiar opalescence it sometimes exhibits. It occurs in crystals derived from the rectangular prism. It is of vitreous lustre, specific gravity 3.5 to 3.8, and hardness 8.5. The crystals are transparent or translucent, and of light shades of green, colored by oxide of iron and sometimes probably by chrome. The finest transparent crystals are cut with facets, and are then known and highly prized by the name of oriental chrysolite or oriental topaz. If opalescent, they are usually cut *en cabochon*, and unless very brilliant are of little value. The mineral consists of nearly 80 per cent. of

alumina and 20 of glucina; a small proportion of oxide of iron is usually present. It is found in Brazil and Ceylon, in rolled pebbles among alluvial deposits; in the Ural, associated with beryl in mica slate; in Haddam, Conn., in granite, with garnet, beryl, &c. It also occurs in Vermont, and near Saratoga, N. Y.

CHRYSOLITE (Gr. χρυσός, gold, and λίθος, stone; so named from its color), a common constituent of some eruptive rocks, and also occurring in or among metamorphic rocks, with talcose schist, hypersthene rocks, and serpentine; or as a rock formation; also a constituent of many meteorites. The eruptive rocks, basalt and basaltic lava, consist of chrysolite (the variety olivine), along with labradorite or other feldspar, and augite. It is essentially a silicate of magnesia, with from 6 to 8 per cent. of protoxide of iron.

CHRYSOLORAS, Manuel, a learned Greek of Constantinople, the first who revived the study of Greek literature in Italy toward the close of the middle ages, born about the middle of the 14th century, died at Constance, April 15, 1415. The eastern empire being in danger of overthrow by Bajazet II., Chrysoloras was sent by the emperor about 1390 as ambassador to the western powers to solicit aid against the Turks. He visited Italy, France, and England; but his mission having failed, he was induced about 1395 to become a public teacher of Greek at Florence. He passed thence to various Italian universities, and was the preceptor of several early Hellenists; among others, of Leonardo Bruni, Poggio, and Guarino of Verona. His *Erotemata*, an introduction to Greek grammar, was the first and long the only channel to a knowledge of that language, save oral instruction; and it was several times reprinted after the grammars of Gaza and Lascaris had come more into use. He wrote many religious works, and letters on various subjects, most of which exist only in manuscript. He enjoyed a high reputation for eloquence and theological learning, was employed by Gregory XII. in negotiations for the reunion of the Greek and Latin churches, and accompanied Pope John XXIII. to the council of Constance, where he died.—His nephew, JOHN CHRYSOLORAS (died 1462), followed him to Italy, and has sometimes been confounded with him.

CHRYSOSTOM, John, a bishop, doctor, and saint of the eastern church, born in Antioch, according to the best authorities, Jan. 14, 347, died Sept. 14, 407. His name was only John, the appellation Chrysostom (Gr. χρυσόστομος, the golden-mouthed), by which he is usually known, not having been given to him until the 7th century. His father, Secundus, who was *magister militum Orientis*, died while John was still in his infancy. Arethusa, his mother, left a widow in her 20th year, resolved to remain single in order to devote her whole life to her boy. Intending him to follow the legal profession, she sought for him the best school of eloquence, and placed him with the re-

owned Libanius, then teaching at Antioch. Libanius, who had formerly had among his pupils the great Basil of Cæsarea, his brother Gregory of Nyssa, and his bosom friend Gregory Nazianzen, had also been the master of the emperor Julian, and his most ardent auxiliary in his endeavor to put down Christianity and restore the worship of the old gods. He welcomed John, soon discovered his genius, labored to develop it, and predicted the preëminence which his favorite pupil afterward attained. At the age of 18 he was practising at the bar, where even then more than one great success laid the foundation of his fame. This, as well as his social position and the virtues of his mother, drew on him the eyes of Meletius, bishop of Antioch, who wished to secure as a member of his clergy one so full of promise. He instructed and baptized him, gave him his first lessons in ecclesiastical science, ordained him lector or reader, and assigned him a residence beneath his own roof. This was not what his mother had designed for him; she had set her heart on seeing him foremost in the race for worldly honors, and resisted with all her might his entrance on a career so different. She represented to him that for love of him she had in youth renounced all earthly joys, and that he must not think of forsaking her now when old age and its infirmities were fast approaching. It was all in vain. The same wave of ascetic fervor which was carrying away into solitude and the austerities of monastic life the very élite of Christian youth, bore John into the mountains which surrounded his native city. For six years, two of which were spent in a hermitage, he gave himself up to a life divided between the study of the Scriptures and prayer, mortifying his body meanwhile with such rigor that his limbs were nearly paralyzed. The urgent solicitations of his friends at length drew him back to Antioch, where the pallor of his countenance and his extreme emaciation touched all beholders with pity or veneration. Several years passed before he was ordained deacon. In 381 Meletius died. A rival Christian faction, with Paulinus as its bishop, had divided the church at Antioch. John, while yet a deacon, strove in vain to heal the schism. Flavian, successor to Meletius, appreciated his learning, eloquence, and disinterestedness. So great, indeed, was the esteem in which he was held throughout Asia Minor, that even before his elevation to the priesthood the neighboring bishops sought to raise him to the episcopal office. He shrank from the honor and responsibility, but induced his friend Basil to accept the proffered rank. In 386 John became a priest, and commenced his course as a preacher. He was justly considered even then as the shining light of the eastern church. In 397 the see of Constantinople became vacant by the death of Nectarius. For three months rival candidates and contending factions sought to no purpose to fill the coveted see. The

eunuch Eutropius, then all-powerful at court, and who had heard John's preaching, submitted his name to the emperor Arcadius. The latter approved of the choice; and forthwith a messenger was sent to Asterius, prefect of the East, who resided at Antioch, bidding him to secure by some stratagem the person of the presbyter John, and send him to Constantinople. John was invited by Asterius to accompany him on a visit to a new church just erected outside of Antioch, and his chariot was driven amid an armed escort toward the Bosphorus. After the first emotion of surprise and anger, John thought he saw in all this the hand of an overruling Providence, and submitted passively. The episcopal chair of Constantinople, in which John now found himself, had a few years before been adorned by Gregory Nazianzen. Nectarius, whom Theodosius chose as his successor, had not even been baptized when, to his dismay, he, in the midst of the second general council, saw himself raised to such an exalted rank. But he discharged his episcopal functions with a careful piety, charming Theodosius and his court by his majestic presence and graceful manners, and dispensing in the patriarchal residence a princely hospitality to the many churchmen whom business drew to the capital. Chrysostom brought a new spirit to these halls. He resolved to make his household a model for every household of churchman and layman within his jurisdiction, and his own life a mirror in which every bishop and priest should see what they must be themselves in order to be true shepherds in Christ's flock. He made a monastic frugality preside over his table and all his domestic expenses. The rich furniture of his predecessors and their abundant wardrobe of silks and cloth of gold were sold at auction, and the proceeds given to the poor. Nectarius had purposed erecting a magnificent basilica, and collected a large quantity of precious marbles and other rare building material. John did not hesitate to sell them for the benefit of the needy classes. The very sacred vessels which he judged too costly for the altar were similarly disposed of. This displeased the clergy, while the people were taught to attribute these reforms to parsimony or avarice. But when the poorly clad archbishop appeared in the pulpit of St. Sophia, his hearers forgot everything but that they possessed a man of God in their midst. It is impossible to study his works without being impressed with his deep devotion to the people. Hence, in Constantinople as at Antioch, whenever he preached the largest edifices could not contain the crowds who flocked to hear him. They surrounded him in the streets, pouring blessings on his head as he passed along; and when his liberty or his life was threatened at a later period, they watched night and day around his dwelling. "I love you," he one day exclaimed to the worshipping throng—"I love you as you love me. What should I be without you? You are to me fa-

ther, mother, brothers, and children; you are all the world to me. I know no joy, no sorrow, which is not yours." This popularity constituted one great source of his power, and he used it in his vain attempt at reform both in court and church. Eutropius, who had been mainly instrumental in his elevation, did not find favor with the archbishop, who denounced his tyranny and the corruption which he encouraged in every branch of the administration. He retaliated by having a law passed which repealed or abridged ecclesiastical immunities, and in particular limited the right of asylum granted to churches. John inveighed against the extravagance and licentiousness of the court. Arcadius dreaded the remonstrances which tended to rouse him from his unmanly love of ease, and the empress Eudoxia hated the man who dared to reprove openly her illicit amours. The courtiers and ministers of state shared their master's enmity, and only waited for an opportunity to make the archbishop feel the weight of their resentment. Eutropius fell into disgrace and fled for his life to the church of St. Sophia, where Chrysostom gave him a shelter, and protected him against the united rage of the courtiers, the military, and the populace. But it was only for a time. Eutropius was induced to leave his asylum, and perished by the hands of Eudoxia's satellites. She now ruled with absolute sway both the emperor and the empire. Her avarice was equal to her ambition, and she went so far as to take open possession of a vineyard which the owner would neither sell nor give up to her. Chrysostom denounced her from the pulpit as a second Jezebel. This brought matters to a crisis. Theophilus, bishop of Alexandria, who had himself aspired to the succession of Nectarius, found new matter of complaint as well as of hatred against Chrysostom in the toleration which the latter extended to some monks expelled from Egypt and excommunicated on account of their attachment to Origen and his doctrines. This caused the accusation of heresy to be made against the archbishop, although at that time no council had condemned the opinions attributed to Origen. Chrysostom summoned before himself every member of his clergy in order to examine into the scandalous reports about their relations with deaconesses and other women. He reformed or rebuked wherever he found just cause; and thus there was wide-spread discontent among the clergy. It had been reported to him that the episcopal office was bought and sold in the provinces dependent on his patriarchate. In the midst of winter he set out, visiting every diocese, and before he returned to Constantinople deposed 13 bishops convicted of simony and immorality. He even extended his visitation into provinces which owed him no obedience, and there exercised the same rigor against the guilty. This raised a great outcry against him, and gave the advantage to his enemies. Eudoxia and Theophilus

joined hands; and in 403 a council of 36 bishops assembled at Chalcedon, a suburb of Constantinople. There Chrysostom was accused, among other crimes, of pride, oppression of the clergy, inhospitality, avarice, gluttony, undue familiarity with women, and high treason. He refused to appear before his self-constituted judges until their president, Theophilus, and three other bishops, his declared enemies, had been excluded. Meanwhile he continued to give his usual homilies in the cathedral, and the people watched unceasingly his coming and going lest any evil should befall him. He was found guilty and deposed from his see, and a new bishop was appointed by the council and approved by the emperor. At length his house was surrounded in the night by soldiers, and himself borne off into exile at Nicæa. The people on hearing this rose and besieged the imperial palace, demanding his instant recall. An earthquake happened at this very moment, and seemed even to Eudoxia a manifest sign of the divine displeasure. She rushed into the presence of Arcadius and besought him to lose not one moment in bringing back the exiled archbishop. But his return did not cause the court to mend its morals, nor the city to lay aside its love of the most costly pleasures. The connection of the empress with the count John was now a subject of comment in every household, while the courtiers tried to cloak over the scandal by showing new honor to Eudoxia, and she endeavored to divert the attention of the populace by inventing for them new games in the circus. The erection of a silver statue to her in the square adjoining the church of St. Sophia was made the occasion of the most extravagant festivities, at a time when the people were suffering from want. The archbishop publicly reproved the people for their love of dissipation, and as openly blamed those whose vanity had caused this display. The empress took mortal offence, and threatened a second exile. The courtiers, too, replied to the archbishop's denunciation by inaugurating a new feast, in which the honors paid to the statue verged on idolatry. Chrysostom was not to be intimidated. On appearing in the pulpit, he alluded in his commentary on the gospel to Herodias dancing, and demanding as a reward the head of John. The allusion was too transparent. This time the court resolved to take no half-way measures. A second assembly of bishops was summoned, more numerous than the first; and, although 42 among the number were faithful to Chrysostom, he was condemned. In 404, six years after he had been forcibly borne off from his native Antioch to assume the spiritual government of the capital, when every appeal to the Roman pontiff had only increased the rage of his enemies, and the efforts made to assemble a full council had proved abortive, he was compelled to set out for a second exile. Feeble in body, but unbroken in spirit, the high-souled old man traversed Asia Minor, and

took up his abode in Cucusus, a town of the Armenian Taurus. Again the indignant populace arose to demand his recall; but, although in their fury they burned to the ground the senate house and the metropolitan church, the emperor firmly withstood all their clamor. The devoted adherents of the exiled archbishop would not acknowledge while he lived the jurisdiction of any other, and, under the name of "Johannites," they worshipped apart until his remains were brought to Constantinople in 438. For about 18 months Chrysostom resided in Cucusus, when an attack of the Isaurians compelled him to take refuge in the distant stronghold of Arabissus. In the latter place, as in the former, he continued to be the light and life of the Asiatic church. At length a new decree banished him to the remote desert of Pityus. On foot, bareheaded, beneath a burning sun, he was driven pitilessly along by his military escort, until he broke down on reaching Comana in Cappadocia. He felt that the end was at hand; and putting on a white robe, he dragged himself feebly a few miles further to the tomb of St. Basiliscus, where he laid himself down to rest for ever. The surrounding country flocked to his obsequies, and honored his remains as those of a man of God. Thirty years later the entire population of Constantinople, headed by Theodosius II., welcomed the relics back with solemn pomp and rejoicing.—Chrysostom was a voluminous writer. The best edition of his works is that of the Benedictines, in Greek, with a Latin translation (13 vols. folio, Paris, 1718-'38; reprinted in Venice, 1734-'41; in Paris, 1834-'39; and in Migne's *Patrologia*, 1859-'60). A translation into English of his homilies is contained in the "Library of the Fathers" (Oxford, 1842-'53). Most of his works are homilies and commentaries on the Bible. A minute analysis of his writings is contained in Butler's "Lives of the Saints." His biography has been written, among others, by Neander (2 vols., Berlin, 1821-'2; 3d ed., 1848), Perthes (English translation, Boston, 1854), Rochet (Paris, 1866), and Stephens ("St. Chrysostom, his Life and Times," London, 1872).

CHRZANOWSKI, Adalbert, a Polish general, born in the palatinate of Cracow in 1788, died in Louisiana in 1861. He took part in Napoleon's campaign against Russia (1812), and fought at Leipsic (1813), under the walls of Paris (1814), and at Waterloo (1815). After the fall of Napoleon he took service in the national army of Poland, at that time reorganized as a kingdom by the emperor Alexander I., and served under Diebitsch in Turkey (1828-'9). Having been made lieutenant colonel, he was at Warsaw when the Polish revolution of 1830 broke out. Adhering to the provisional government, he was appointed commander of the fortress of Modlin, January, 1831, and subsequently chief of Skrzynecki's staff. He distinguished himself by his defence of the line of the Wieprz, by his victory at Kock, by his successful operations in Pod-

lachia, and by his retreat to and from Zamosc, whence he carried a large park of artillery to the capital. Having been made general of brigade, he was further promoted to the rank of general of division after the victory of Minsk (July 14); but an interview held with Gen. Thiemann, the object of which was not divulged, roused suspicion against him, which was strengthened by his opposition to strong measures, and by the inactivity of Skrzynecki, who followed his suggestions. But in spite of his freely uttered misgivings as to the final success of the struggle, he retained his command, and after the events of the night of Aug. 15 was appointed governor of Warsaw under Krukowiecki. His behavior, however, during the storming of Warsaw, and his staying in the conquered capital, which he was allowed to leave afterward with a Russian passport, seemed to confirm the charges against him. After his arrival at Brussels a formal protest was sent to the Belgian government from the Polish organization in Paris against his reception as a Polish refugee. In 1849, after a lapse of 18 years spent in obscurity, he was chosen by Charles Albert of Sardinia as commander-in-chief, though only with the rank of lieutenant general, in his second war against Austria. His arrangements, which made Novara and the highway to Milan the centre of operations, and neglected the lines of the Ticino and Po, and the unexpected advance of Radetzky, who crossed the Po at Pavia and cut off the corps of Ramorino, combined to produce the disaster of Novara (March 23), which terminated the short campaign and the political career of Charles Albert. Chrzanowski and Ramorino were both charged with treachery, and the latter was executed. Chrzanowski put forth an elaborate vindication of his conduct, returned to Paris in 1850, and some time after emigrated to America.

CHUAPA, a river of Chili, forming the boundary between the provinces of Coquimbo and Aconcagua. It rises on the W. slope of the Andes, near the volcano of Chuapa, and falls into the Pacific, in lat. 31° 38' S., after a W. course of about 125 m. Its chief tributary, the Illapel, joins it on the north near the town of the same name.

CHUB, or **Chevin** (*leuciscus cephalus*, Flem.), a common fresh-water fish, of the family *cyprinidae*. It is abundant in almost all the slow-running, soft, clear streams of England; and sufficiently plentiful, of a kindred although distinct species, in similar waters of the United States. (See DACE.) In all modern languages this fish takes its name from the head, which is of somewhat inordinate size. In old English it is called *cop*, in French *têtard*, and in Italian *capitome*. It considerably resembles the carp in form, but is longer and scarcely so thick. The body is oblong, rather round, and of a pretty equal thickness in the greater part of the slope. The scales are large; the irides and cheeks silvery; the head and back of a

deep dusky green; the sides silvery, but in summer yellow; the belly white; the pectoral fins of a pale yellow; the ventral and anal fins red; the tail forked, of a brownish hue, but

Chub (*Leuciscus cephalus*).

tinged with blue at the end. The average weight does not exceed half a pound, though it sometimes weighs more than two pounds. The flesh is little esteemed, being coarse and full of small hairy bones; the roe, however, is excellent; and the head and throat are the best parts, being moderately gelatinous. The haunts of the chub are in rivers whose bottoms are of sand or clay, or which are bounded by clayey banks; particularly in deep holes, shaded by trees, weeds, &c. It frequently floats on the surface, and is sometimes found in streams and deep waters where the currents are strong; in ponds fed by rivulets it grows to a large size. It spawns in April, and is in the best condition in December and January. It affords little sport to the angler, though it will bite freely at the worm, the grasshopper, and the natural or artificial fly; for, when once hooked, the mouth is so tough and leathery that the hook is certain to keep its hold, while the fish has so little pluck or spirit that it will allow itself to be pulled out by main force. It is a shy and wary fish, and is affected by the slightest movement of the water, or by the shadow of anything fleeting over it, as that of a flying bird or a waving bough.

CHUBB, Thomas, an English theological writer, born at East Harnham, Wiltshire, in 1679, died at Salisbury, Feb. 8, 1746. His parents were poor, and gave him very little education; and nearly all his life he followed the business of a tallow chandler at Salisbury. He however acquired considerable general knowledge, and delighted especially in theological studies. When the controversy arose concerning the Trinity, after the publication of Whiston's "Primitive Christianity" in 1711, he wrote an essay entitled "The Supremacy of the Father Asserted." This being replied to, he rejoined with "The Supremacy of the Father Vindicated." He wrote many other tracts and essays, among which were "A Discourse on Reason as a Sufficient Guide in Matters of Religion," "Inquiry about the Inspiration of the New Testament," "The Doctrine of Vicarious Suffering and Intercession Refuted," "On Future Judgment and Eternal Punishment," "Time for Keeping a Sabbath,"

&c. He denied the vicarious suffering of Christ, and the divine authority of the positive institutions of Christianity, but maintained that Jesus was sent by God as a moral instructor. He is included by Leland among the "Deistical Writers in England," and was admired by several prominent men of his day.

CHUCUITO, Chucuyto, or Chuquito. I. A province of the department of Puno, in Peru; pop. about 75,000. It is rich in gold and silver mines, and raises large numbers of cattle. **II.** The capital of the province, situated on the W. bank of Lake Titicaca, at the mouth of a small river rising in the Andes, about 15 m. S. E. of Puno and 95 m. E. of Arequipa. In its vicinity are remarkable remains of antiquity. It has greatly declined from its former prosperity, the population, which was about 30,000 in the beginning of the last century, being now only about 5,000.

CHUCK WILL'S WIDOW. See GOATSUCKER.

CHUDLEIGH, a market town of Devonshire, England, on a hill near the left bank of the Teign, 8 m. S. W. of Exeter; pop. in 1871, 6,612. It was almost destroyed by fire in 1807, and has since been rebuilt. It contains a church, several chapels, an endowed grammar school, national schools, and various charities. It is famous for its cider, and once had manufactories of woollens. In the vicinity are quarries of marble and limestone, and some remarkable limestone rocks, with curious caverns which the popular superstition of Devonshire points out as the abode of fairies.

CHUMBUL, a large river of Hindostan, rises in the N. slope of the Vindhya mountains at a height of 2,019 ft., flows N. for some distance, then N. E., and finally joins the Jumna about 90 m. S. E. of Agra. Its total course is estimated at 570 m. Besides other streams, it receives the rivers Sind and Parbuttee, and it is during a large part of its course the boundary between the Rajpoot provinces and Gwalior.

CHUNAR, or **Chunargurh**, a town and fortress of British India, in the district of Mirzapoor, on the right bank of the Ganges, 16 m. S. W. of Benares, and 395 m. N. W. of Calcutta; pop. about 12,000. It is a place of considerable strength, possesses a small citadel, extensive magazines, governor's house, hospital, and prison. The fort is built on a solid rock which rises abruptly and projects into the river. The church missionary society has a church, and there is a chapel for the use of Roman Catholic soldiers. In 1768 the fort, with its territory, was ceded to the East India company, and was for some time the principal military depot for the Northwest Provinces. It is an invalid station for European troops, although during the sultry season the intense heat renders the place ill adapted for a sanitarium. Outside of the town is the tomb of Kasim Solyman and of his son, who are reputed as saints by the Mussulmans.

CHUND, or **Chand**, a Hindoo poet, of the Rajpoot tribe, who flourished in the 12th century.

He wrote a poem, said to contain 100,000 stanzas, in which he alludes to or treats of almost all branches of knowledge, and gives a sort of general history of his nation during the period in which he lived, celebrating the exploits of the Rajpoot nobles, and especially of Prithwiraja, the last Hindoo king of Delhi, for whom he acted as court bard. His poems are still very popular among the Rajpoots. Col. Tod published an account of the life and writings of Chund in the first volume of the "Transactions of the Royal Asiatic Society," giving some translations from these poems.

CHUPRA, a town of Bengal, capital of the district of Sarun, British India, situated at the junction of the Ganges and the Gogari, 32 m. N. W. of Patna, and 330 m. N. W. of Calcutta; pop. about 30,000. It has a considerable trade in cotton, sugar, and salt-petre, with towns on the rivers. With the exception of the places of worship and the dwellings of the wealthy native merchants, the houses are built of mud, with tiled roofs. The town has little breadth, but extends a mile along the river. It is only a few feet above the level of the Ganges, which is here navigable during the rains, but inaccessible from October to July.

CHUQUISACA. I. A department of Bolivia, between lat. 17° and 21° 25' S., and lon. 62° and 67° W., bounded N. by the departments of Cochabamba and Santa Cruz, E. by Santa Cruz, S. by Tarija and Potosí, and W. by Oruro; area, 72,793 sq. m.; pop. 219,788. The surface is mountainous and in portions arid, but the valleys are noted for fertility and are generally well cultivated, yielding large crops of corn, potatoes, and clover. It is divided into the provinces of Chuquisaca, Cinti, Tomina, and Yamparaes. The province of Chuquisaca is the most northerly and most elevated part of the department, and contains numerous and rich mines of gold and silver.

II. The capital of the department and of Bolivia, called more generally Sucre. (See **SUCRE**.)

CHURCH (Gr. *κυριακόν*, consecrated to the Lord; Saxon, *kyrck*; Scandinavian, *kirka*; Slavic, *cerkiew*; Scotch, *kirk*: the common root in these forms did not pass into the Romanic languages, but from the New Testament term *ἐκκλησία*, a congregation, sprang the Lat. *ecclesia*, the Span. *iglesia*, the Fr. *église*, &c.), in its most general sense, the whole collective body of Christians. Its narrower senses are, a body of Christians adopting one creed, and organized under the same ecclesiastical government, as the Anglican church; the Christians of a particular province or city, as the church of Antioch; or a society organized for worship in the same edifice. In the Scriptures the name is also given to the body of Jewish believers, the Jewish church being composed of all those who followed the law of Moses. The Christian church is the society of those who profess the religion of Jesus Christ. The society of the faithful upon earth is usually called

the church militant, and the society of the saints in heaven is called the church triumphant. In the New Testament the name is once applied to a single family of Christians. (See **CHRISTIANITY**.)—Christians have always given the appellation church to the edifices designed for public worship. The ancient churches had an *atrium*, or open space surrounded with walls, before the entrance; in the centre of this there was a fountain, in which all washed their hands or faces before entering the church, as an emblem of the purity of soul which they should possess. Before the door there was a covered court, the roof of which was supported by columns; in this were placed the first class of penitents, who were called *flentes*. In the interior, the part of the church near the door was called the *narthex*; in this the catechumens and the penitents, who were called *audientes*, were placed. Then came the nave, the lower part of which was occupied by the penitents called the *prostrati*; while the laity were arranged, the men on one side and the females on the other, in the remainder of the nave. In the centre was the *ambon*, or pulpit, large enough to contain several persons who acted as chanters. The choir was separated from the nave by *cancelli*, or rails; in this were situated the altar, the throne of the bishop, and the seats of the priests. As it terminated in a semicircle, it was called the *apsis*. A curtain drawn round the altar concealed it from the view of the catechumens, and from those who were unbelievers, during the time of the divine mysteries. (See **ARCHITECTURE**, and **CATHEDRAL**.)

CHURCH, Benjamin, an American soldier in the early Indian wars, born at Duxbury, Mass., in 1639, died at Little Compton, Jan. 17, 1718. He was engaged in several severe skirmishes in King Philip's war, one of which was in a swamp near Bridgewater; and in August, 1676, he commanded the party by which Philip was killed. Commissioned in 1689 as commander-in-chief of an expedition against the eastern Indians, he proceeded up the Kennebec, visited the forts in that vicinity, and rescued Casco for a time. He made four other expeditions against the Indians in Maine, once landing at Maquoit, and thence going to Pejepscot fort, in Brunswick, once again going up the Kennebec, and twice ascending the Penobscot and Passamaquoddy, and doing much damage to the French and Indians on these rivers. Under his direction, and from his minutes, his son Thomas wrote a history of Philip's war (1716; last ed., with notes by H. M. Dexter, 1865).

CHURCH, Benjamin, an American physician, born at Newport, R. I., Aug. 24, 1734, lost at sea in May, 1776. He graduated at Harvard college in 1754, and became very successful as a physician and surgeon. He was also a polished speaker, and the author of several spirited poems. Before the breaking out of the revolutionary war he was a leading whig poli-

tician, a member of the provincial congress of 1774, and of the committee of safety, and became physician general to the patriot army. He lived extravagantly, became pecuniarily embarrassed, and in 1775 was found to be in treasonable correspondence with Gen. Gage. He was convicted of this offence by a court martial over which Washington presided, was expelled from the house of representatives, and imprisoned at Norwich, Conn., by order of congress, and denied the use of pen, ink, and paper. He was released in the spring of 1776, and permitted to embark for the West Indies on account of his failing health; but the vessel was never again heard from. An account of his trial is contained in the "Massachusetts Historical Collections," vol. 1.

CHURCH, Fathers of (*patres ecclesie*), those Christian teachers and writers, from the 2d to the 13th century, who were eminent for their orthodoxy, genius, and beneficent influence upon the church. They were preceded by the apostolic fathers, and include several of the scholastic doctors. Protestants usually limit the title to those ecclesiastical writers who lived between the 2d and 6th centuries. That department of theological study which embraces the life, writings, and doctrines of the church fathers is termed patristics or patrology, and is both curious and valuable with reference to exegesis, dogmas, and church history. The most distinguished of the Greek fathers recognized by Protestants are Irenæus, Clement of Alexandria, Origen, Athanasius, Cyril of Alexandria, Basil the Great, Gregory of Nazianzus, Eusebius of Cesarea, Chrysostom, and Theodoret; of the Latin fathers, Justin Martyr, Tertullian, Lactantius, Cyprian, Hilary of Poitiers, Ambrose, Augustine, Jerome, and Gregory the Great. The Roman Catholics exclude from this list Tertullian, Origen, and Eusebius, on account of the heterodoxy of some of their works, but add to it John of Damascus, Peter Damian, Anselm, Bernard, Thomas Aquinas, Bonaventura, and others of the early mediæval theologians. Most of the patristic writings have been several times edited separately, and the careful Benedictine editions are still esteemed among the best. Of the general collections, the most important are the *Maxima Bibliotheca Veterum Patrum* (27 vols., Leyden, 1677), containing the Greek fathers in a Latin translation, and valuable notices of mediæval theologians; the *Bibliotheca Veterum Patrum et Antiquorum Scriptorum Ecclesiasticorum*, by Galland (14 vols., Venice, 1765-'81); the *Patrologiæ Cursus Completus*, by the abbé Migne (the most extensive of all collections, in 389 vols., Paris, 1840-'67); and the collection by Cardinal Mai, *Nova Collectio* (10 vols. 4to, Rome, 1825-'38), *Spicilegium Romanum* (10 vols. 8vo, 1839-'44), and *Nova Patrum Bibliotheca* (7 vols. 4to, 1844-'53). A collection by Combes, *Bibliotheca Patrum Concionatoria* (8 vols. fol., Paris, 1662), was to be republished in 30 vols. 8vo, but only the first volume has

appeared (1852). Collections of extracts were made by Grabe (Oxford, 1698), Rösler (Leipsic, 1776-'86), Guillon (Paris, 1833-'40), and Thilo (Leipsic, 1853-'4). Among the best aids to patristic studies are Möhler's *Patrologie* (Ratisbon, 1839-'40), Engelhardt's *Leitfaden zu patristischen Vorlesungen* (Erlangen, 1822), and Charpentier's *Études sur les pères de l'Église* (Paris, 1853). In 1839 a "Library of Translations from the Fathers," edited by E. B. Pusey, John Keble, and C. Marriott, was commenced at Oxford, of which about 40 volumes have appeared.

CHURCH, Frederick Edwin, an American landscape painter, born in Hartford, Conn., May 4, 1826. He was a pupil of Thomas Cole for two years. Among the works which first brought him into notice was a view of East Rock, near New Haven; and a number of scenes in the Catskill mountains added to his reputation. In 1853 he went to South America, visiting New Granada and Ecuador, where he obtained material for a number of pictures. His views of the great mountain chains of those countries attracted much attention for their careful elaboration and warmth of color. He made a second journey to South America in 1857, and brought back a large number of sketches, from which he produced his "Heart of the Andes," "Cotopaxi," "On the Cordilleras," and other pictures, which gave him a high rank in his profession. In 1858 he painted a large view of Niagara Falls, representing the Horseshoe Fall as seen from the Canadian shore near Table Rock, which is generally regarded as his masterpiece. This picture he reproduced on a larger scale in 1868. He afterward went to Jamaica, to make studies of tropical scenery, and in 1868 visited Europe and the Holy Land. His large picture of "Damascus" was painted in Rome in 1869, his "Jerusalem" in New York in 1870, and his "Parthenon" also in New York in 1871. His "Tropical Scenery," painted from sketches taken during his West Indian trip, was exhibited in New York in 1873. It is much smaller than many of his canvases, being only about 40 inches in length, but exhibits many of his best characteristics. Mr. Church resides near Hudson, N. Y., but has his studio in New York city, and was formerly one of its commissioners of parks.

CHURCH, John Hubbard, D. D., an American clergyman, born at Rutland, Mass., March 17, 1772, died at Pelham, N. H., June 13, 1840. He graduated at Harvard college in 1797, and was for nearly 40 years pastor of the Congregational church of Pelham. He was devoted to benevolent enterprises, and was officially connected with Dartmouth college, Andover theological seminary, Phillips academy, and with various missionary, Bible, and tract societies, which he served with great zeal and efficiency. He published about 25 sermons, besides various articles in religious periodicals.

CHURCH, Sir Richard, a commander in the Greek war of independence, born in England in 1780, died in Athens, March 20, 1873. He

entered the army in 1800, and having spent many years in the British and Neapolitan service, and held in 1813 the command of a Greek infantry corps, he in 1827 joined the Greeks in their struggle for independence. He was appointed commander-in-chief of the Greek forces, and ordered by the national assembly of Trœzene to march to the relief of Athens. His attempt to raise the siege failed, partly from want of prudence, partly from the dissensions which sprang up among the Greek chieftains. He continued in the service of Greece till 1829, when, owing to his being a foreigner, and to the personal hostility and jealousy of Capo d'Istrias, he was forced to resign. He retired to Argos, and was living in obscurity when he was ordered in 1830 to leave the Greek territory. He remained, however, and when Capo d'Istrias was assassinated in the following year, he was again placed at the head of the army, though he continued to oppose the administration of Augustin Capo d'Istrias, who had succeeded his brother as president. On the establishment of the kingdom of Greece he was appointed a councillor of state, afterward became a member of the senate, and remained for many years at the head of the Greek army and navy. His death was honored by a national mourning at the request of the king.

CHURCH OF ENGLAND. See ENGLAND, CHURCH OF.

CHURCHILL, a W. central county of Nevada; area, 5,800 sq. m.; pop. in 1870, 196, of whom 16 were Chinese. Carson, Humboldt, and Walker rivers water portions of the county. Near the centre is a depressed basin, in which lie the "sinks" or lakes of Carson and Humboldt rivers. In this basin are found salt, bicarbonate of soda, and other like substances. Much of the surface is mountainous. The arable land along the streams amounts to about 50,000 acres; the grazing lands are more extensive. There is also some land that might be made productive by irrigation, but the greater part is unfit for agriculture. The Central Pacific railroad passes through the N. W. part. Gold and silver are found. There is one quartz mill for the production of gold, with 10 stamps and 3 arastras. The chief productions in 1870 were 559 tons of hay, 7,145 bushels of barley, and 2,224 lbs. of wool. There were 130 horses, 137 milch cows, 741 other cattle, and 772 swine. Capital, Stillwater.

CHURCHILL, called also *Mississippi* and *English River*, a river of British America, rises in Lake Methy, flows S. E. through Lakes Buffalo and La Crosse, runs thence almost due E. to Nelson's lake, and after traversing a woody region in a N. E. direction and expanding into considerable sheets of water, falls into Hudson bay. It is about 700 m. long.

CHURCHILL, Charles, an English poet, born in Westminster in February, 1731, died in Boulogne, Nov. 4, 1764. He studied for a time at Trinity college, Cambridge, but did not

graduate. At the age of 17, although without any means of subsistence, he married, and his father, a curate and lecturer at Westminster, took him and his wife into his house and supported them on condition of his adopting the clerical profession. In 1756 he was ordained, and, having first held a curacy in Somersetshire, was afterward inducted into a small country preferment which belonged to his father. In 1758, on the death of his father, he succeeded to his curacy. During this period he was exemplary in his conduct, although he himself declares that he was doing violence to his own feelings, and that he was but an idle pastor and drowsy preacher. Differences with his wife, increasing debts, and finally the evil example of a young friend, the poet Robert Lloyd, plunged him into all the dissipations and irregularities of the town. He was compelled to give up his curacy, and was only saved from incarceration by the interposition of his friend's father, Dr. Lloyd, a master in Westminster school. His first poem, published in 1761, was the "Rosciad," a satire on the theatrical world of the day. The criticisms upon this performance drew out the stinging "Apology to the Critical Reviewers," in which he attacked the wits as he had the players. In 1762 he associated himself with Wilkes, and wrote frequently for the "North Briton." The "Prophecy of Famine," a satire on Scotchmen, directed against the Bute administration, attained great popularity. He was involved in the proceedings against the "North Briton," in which Wilkes defended the liberties of the subject against the stretch of kingly prerogative. He defended his profligate course in "Night," and wrote also "The Duellist," "The Author," "Gotham," "The Candidate," "The Farewell," "Epistle to Hogarth," "The Times," and many other satirical pieces. He died while on a visit to Wilkes, and was buried at Dover. "No English poet," says Southey, "had ever enjoyed so excessive and so short-lived a popularity; and indeed no one seems more thoroughly to have understood his own powers; there is no indication in any of his pieces that he could have done anything better than the thing he did." His complete works were published in 1804.

CHURCHILL, John. See MARLBOROUGH, DUKE OF.

CHURCHMAN, William H., a blind man, superintendent of several institutions for the instruction of the blind, born in Baltimore, Md., in 1818. As a pupil of the Pennsylvania institution for the blind, he acquired a good mathematical education, and attained proficiency in music. In 1840 he became an assistant teacher of music and other branches in the Ohio institution for the blind at Columbus. In 1844 he was appointed principal of the Tennessee institution for the blind. He resigned after two years' service in consequence of ill health, and in 1847 was chosen superintendent of the Indiana institution for the blind at Indianapolis,

over which he presided till 1853. The ensuing year he established a young ladies' seminary at La Porte, Ind., which, after a little more than a year of successful progress, was broken up by the destruction of the buildings by fire. He received soon after the appointment of superintendent of the Wisconsin institute for the blind, at Janesville.

CHURCH RATE, a tax imposed on the parishioners and occupiers of land in a parish of England for church repairs. The tax is proposed by the church wardens, and must be voted by a majority of the parishioners in vestry assembled. It is distinct from tithes, from which in early times the repairs were made. Before the reformation the levy of church rates might be compelled by spiritual censures and punishments, but since then it has been generally understood to rest entirely in the discretion of the parishioners. Recently, however, in the Braintree case, and the case of St. George's, Colgate, Norwich, efforts were made to compel the payment of a levy made by the wardens where the parish had refused to vote it, and to punish parishioners who had voted against the tax; but in each instance without success. The decisions in these cases strengthened the opposition of dissenters and others, which previously had been troublesome, and at length, by statutes 31 and 32 Victoria, c. 109, the payment of church rates was made no longer compulsory. The rate was abolished in Ireland in 1823. In Scotland the burden of church repairs is by custom on the heritors or owners of land in the parish subject to ecclesiastical charges.

CHURN, a vessel in which cream is agitated to separate the butter from the other portions. It has various forms, the simplest and most generally preferred being the common dash churn, which is either a cylindrical or barrel-shaped vessel, standing upon one end and having a cover fitted to the other, with a hole in its centre for the passage of the handle of the dasher. This is the instrument for producing the agitation of the cream, and consists of a wooden rod a little more than an inch in diameter and from three to four feet long, having two boards attached crosswise at the lower end, of a length somewhat less than the diameter of the churn. The form and size of these cross pieces are important, as upon them depends the proper agitation of the cream. The motion which has been found to give the best results in churning is that which produces a thud or shock, such as would be given if a keg or small slender barrel, partly filled with a liquid and suspended in a horizontal position by both ends, were swung in one direction, endways, and then suddenly stopped; and, indeed, this form of churn has been used in Holland, England, and the United States, and for making small quantities of butter is probably the best. It is called a swing churn. An ingenious contrivance for imparting a similar motion to the contents of the churn has been invented in England. It

consists in revolving a barrel-shaped vessel upon a diagonal axis, by means of which each end is alternately raised and lowered, thereby throwing the cream from one end to the other. Wheel churns of an almost endless variety have been invented, and some of the simpler forms answer the purpose intended very well; but they are all inferior to the dash and swing churns. Some combine aëration with agitation, by forcing streams of air through the cream; but such contrivances are now regarded by all good butter makers as worse than useless, because, although they may quickly effect the rupture of the butter globules, they incorporate the sacs and other portions with the butter, rendering it liable to become rancid by fermentation. The design in many of the inventions has been to hasten the operation of churning; but it has been found that when cream is in the best condition for making butter, the time occupied should be from 40 minutes to one hour. (See **BUTTER**.)

CHURRUCÁ Y ELORZA, Cosme Damian de, a Spanish naval officer, born at Motrico, in the province of Guipuzcoa, Sept. 27, 1761, died at Trafalgar, Oct. 21, 1805. He distinguished himself at the siege of Gibraltar in rescuing some of the survivors from the floating batteries, after the latter had been destroyed by the English. Having received an appointment in a Spanish surveying expedition to the strait of Magellan, he wrote an admirable diary of his exploration of Tierra del Fuego, which was published at Madrid in 1793. In 1791, being then in command of a frigate, he was placed at the head of an expedition fitted out for the purpose of surveying the coasts of the gulf of Mexico. The war which soon after broke out between Spain and France interrupted this work, and compelled Churruca to leave his task unfinished; but he had already completed 24 charts of the coasts of Cuba, Hayti, Porto Rico, &c., some of which have since been published. He was afterward sent as an envoy to Brest, and was received with distinction by Napoleon, then first consul. In October, 1805, he was in command of a frigate at Cadiz, and shortly before the battle of Trafalgar wrote to a friend, "If you hear that my ship is taken, know for certain that I am dead." In that battle, his leg having been shot away by a cannon ball, he died three hours afterward.

CHURUBUSCO, a small village about 6 m. S. of the city of Mexico, on the Rio de Churubusco, at which a battle between the Mexicans under Santa Anna, and the Americans under Scott, was fought Aug. 20, 1847. It contains the massive convent of San Pablo. The road to Mexico is an elevated and paved causeway crossing the river by a stone bridge. The banks of the stream have been raised and planted with trees. At this point Santa Anna took a determined stand after the battle of Contreras, to intercept Scott's advance toward the capital. The Americans carried the place after a sharp action. The engagements at

Contreras and Churubusco were fought on the same day, and actually formed one battle. In both actions the American loss was 139 killed and 926 wounded. The Mexican loss was about 4,000 killed and wounded, 3,000 prisoners, 37 pieces of ordnance, many small arms, and much ammunition. The battle of Chapultepec, Sept. 13, was the closing action in this campaign. (See CHAPULTEPEC.)

CHUSAN, or **Chowsan** (boat-like), a group of islands, consisting of one large island with a great number of smaller ones, off the coast of China, about lat. 30° N., lon. 122° E. They are beautifully wooded, abound in floral productions, and contain numerous excellent harbors. The largest island, called also Chusan, is about 50 m. in circumference; pop. about 250,000. The land is carefully cultivated, and rice, wheat, sweet potatoes, chestnuts, walnuts, tobacco, tea, silk, and cotton are produced. The climate is temperate and healthful except in the summer months. Chusan is an intermediate port between Japan and the Chinese ports of Ningpo, Hangchow, and Shanghai. In 1840 the British seized the islands, and held them for a time. As stipulated in the peace in 1842, they were evacuated in 1846, and Hong Kong was ceded to the British in their stead. They were occupied by the British again in 1860, but evacuated the same year. The capital is Tinghai, a walled town about 2 m. in circumference, containing some fine specimens of Buddhist temple architecture.

CHYLE (Gr. *χυλος*, juice), the white, opaque, milky-looking fluid found in the lymphatic vessels of the small intestine during digestion. The lymphatic vessels of the whole body absorb from the tissues in which they are distributed a watery fluid, containing albumen, fibrine, and saline matters in solution. In addition to these substances, however, the lymphatics of the small intestine, while digestion is going on, absorb from them the fatty ingredients of the food. These substances have been reduced by the digestive process to the state of an emulsion; that is, to the condition of finely comminuted particles or granules, less than $\frac{1}{100,000}$ of an inch in diameter, which are held in suspension in the watery or serous parts of the fluid. It is these exceedingly abundant and finely divided oleaginous granules which give to the chyle its opaque white color; and the intestinal lymphatics are therefore called the lacteals, or milk-bearing vessels. The chyle, collected from the intestine by the lacteals, is conveyed to a pouch or dilatation, situated at the posterior part of the abdomen, called the *receptaculum chyli*, whence it is conveyed upward through the chest by a special vessel, the thoracic duct, and finally discharged into the left subclavian vein at the root of the neck. The abundance of the chyle varies with the activity of digestion and the amount of fatty matters present in the food; in the human subject its average quantity is estimated at about 2½ pounds per day.

CHYME (Gr. *χυμος*, sap, moisture), a term formerly applied to the semi-fluid mass of the food which has undergone digestion in the stomach, and is about to pass into the small intestine. It is now known that the food in this condition is simply a mixture of various substances, some of which have undergone complete or partial digestion by the gastric juice, while others are still unaltered, and require the action of other secretions before their digestion will be accomplished. The term chyme, therefore, does not represent any definite substance, and is accordingly seldom employed by physiologists at the present day.

CIALDINI, Enrico, an Italian soldier, born near Castelvetro, Aug. 8, 1811. He is the son of a hydrographical engineer and a Spanish lady. Expelled from the Jesuit college at Reggio on account of his irreverence, though displaying precocious talents, he was sent to Parma to study medicine and the art of design, but joined the revolutionary movement of 1831, and was obliged to take refuge in Paris, where he continued his medical studies, and supported himself by translating into Italian some writings of Voltaire and Rousseau, and some of Velpeau's surgical works. In 1833 he fought in Portugal for Dom Pedro, and in 1835 he entered the Spanish service against Don Carlos, rising to the rank of lieutenant colonel. After the war he served for some time as adjutant of Narvaez at Valencia, where he married a Spanish lady. He was sent to Paris to report upon the organization of the French police, and after the outbreak of the revolution of 1848 joined Gen. Durando at Vicenza. Being severely wounded (June 10), he fell into the hands of the Austrians, but was set free early in 1849, after his partial recovery. He afterward fought against the Austrians as commander of a corps chiefly made up of volunteers. In the Crimean war he became brigadier general, Aug. 1, 1855; and on his return to Turin the king appointed him his aide-de-camp, though that rank is generally conferred only on noblemen. In 1859 he organized the Garibaldian corps of Alpine sharpshooters, and commanded the 4th division of the army, attaining the rank of general of division (June 1) in reward for his services especially at the battle of Palestro. In 1860 he commanded in the brilliant campaign which resulted in the utter defeat of the papal army under Lamoricière at Castelfidardo (Sept. 18), and in the capture of Ancona and other important places, after which he was made general of the army (a rank corresponding to that of marshal in France), simultaneously with Garibaldi and Fanti. On Feb. 13, 1861, he compelled the surrender of Gaeta, and on March 13 that of the citadel of Messina, thus closing the war in southern Italy and Sicily. He declined the titles and pensions offered to him, accepting only a crown of laurel in token of national gratitude. He was elected member of parliament for Reggio, but went in 1861 as lieutenant of the king to Naples, where he did

much to extirpate pseudo-political brigandage. When Garibaldi began his revolutionary movement of 1862, Cialdini was sent to Sicily to preserve order in that island; but the defeat of the former at Aspromonte put an end to this mission, and he resumed the military command of Bologna. In 1864 he became a member of the senate, and urged the removal of the capital to Florence as a strategical necessity. In February, 1865, the king appointed him military commander at Turin. In 1866, as commander of the 4th corps, he operated along the lower banks of the Po, with a view of cutting the Austrian communications east of the quadrilateral. After the disastrous battle of Custoza he was obliged to fall back upon Bologna and Piacenza; but after the battle of Sadowa he was of some service in hastening the retreat of the Austrians toward Tyrol. He succeeded La Marmora as chief of staff, and declined in October, 1867, the mission to Vienna. When Rattazzi's cabinet was broken up on account of the differences with France, the king requested Cialdini to form a new cabinet; but his efforts were unavailing, and in November he became commander-in-chief of the troops in central Italy. In 1869 he had bitter controversies with La Marmora in respect to the disastrous campaign of 1866, and he soon retired from the army in order to be entirely independent as one of the leaders of the opposition in the senate against Lanza's administration. He was one of the signers of the act by virtue of which the throne of Spain was accepted by Amadeus, whom he accompanied as extraordinary ambassador to Spain, but without any official title. In February, 1873, he was sent on a special diplomatic mission to France.

CIBAO, a mountain range nearly in the central part of Hayti, extending about 90 m. N. W. and S. E. The highest summits, forming the culminating peaks of the island, are more than 7,000 ft. high. E. and S. E. of these mountains is an excessively rugged and almost deserted tract; but between the range along the N. shore, from the bay of Monte Christi on the west to Vieux Cap Français on the east, and the Cibao mountain, there is an extensive and fertile valley watered by the Yaque, and known as the plain of Santiago. The principal rivers of the island, as the Neyva, Artibonite, Yuma, and Monte Christi, rise in these mountains; and gold has been found here.

CIBBER. I. Caius Gabriel, a sculptor, born in Holstein about 1630, died in London about 1700. He went to England during the protectorate of Cromwell, and was employed to execute the bassi rilievi on the pedestal of the London monument. He is principally known as the sculptor of the two figures representing raving and melancholy madness, which adorned the principal gate of old Bethlehem hospital, and are now preserved in the new hospital in St. George's Fields. He was in later life employed by the duke of Devonshire in the improvement and decoration of his family seat at

Chatsworth, and built the Danish church in London at his own expense. **II. Colley**, an English poet and dramatist, son of the preceding, born in London, Nov. 6, 1671, died Dec. 12, 1757. After serving as a volunteer in the cause of William of Orange, he commenced his career as an actor in 1689. His success was for many years very indifferent, but he at last attained popularity in the personation of feeble old men and fops. He wrote and adapted about 30 plays of various descriptions, among which are "Love's Last Shift," "Love Makes a Man," "She Would and He Would Not," "The Careless Husband," "The Nonjuror" (his best play, an adaptation of Molière's *Tartuffe*, on which Bickerstaff afterward founded his "Hypocrite"), "The Provoked Husband," and the modern acting version of "Richard III." He also wrote an autobiography, under the title of an "Apology for his Life." He was one of the managers of Drury Lane theatre from 1711 to 1730, and was then appointed poet laureate, in which character he figures as hero of the "Dunciad." **III. Theophilus**, an English actor and author, son of the preceding, born Nov. 26, 1703, died in October, 1758. He appeared on the stage in 1721, and met with some success; but his irregular habits prevented any systematic effort, and he was generally in want. He early married an actress of the name of Johnson, and after her death married Miss Arne in 1734. His extravagance obliged him to retire to France in 1738, and on his return he separated from his wife under very discreditable circumstances. In 1758 he made an engagement with Mr. Sheridan at the Dublin theatre, but perished by shipwreck while crossing the Irish channel. He wrote and adapted several plays, and was concerned with a work entitled "Lives of the Poets of Great Britain and Ireland to the Time of Dean Swift" (5 vols., London, 1753), the authorship of which is claimed for a Scotchman named Shiel, who purchased from Cibber the privilege of using his name upon the title page. **IV. Susannah Maria**, an English actress, wife of the preceding, born in 1716, died Jan. 30, 1766. She was educated in music by her brother, Dr. Arne the composer, made her first public appearance as a singer, and after her marriage performed in tragedy. She is still reputed among the great actresses of the English stage. Handel was so enthusiastic in his admiration of her that he composed parts expressly to suit her voice, and himself instructed her in singing them. Garrick is said to have exclaimed when he heard of her death, "Then tragedy has expired with her." She was buried in Westminster abbey.

CIBOT, François Barthélemy Michel Édouard, a French painter, born in Paris, Feb. 11, 1799. He studied with Guérin and Picot, and painted history, portraits, and genre subjects. Among his works are "Judith going to the Camp of Holofernes," "The Origin of the Sacred Heart," in the church of St. Leu, "The Burial

of Godfrey de Bouillon," "The Victory of Raymond Dupuy," "The Defence of Beauvais," in the gallery of Versailles, "Spring," "Summer," &c. He obtained a medal of the second class in 1836, of the first class in 1843, honorable mention in 1855, and in 1863 the decoration of the legion of honor.

CIBOT, Pierre Martial, a French Jesuit missionary in China, born at Limoges in 1727, died in Peking, Aug. 8, 1780. He was educated in Paris, and distinguished himself by his fine scholarship. He set out for China in 1758. First admitted into the household of the emperor as a gardener, his learning and talent soon gained for him the position of court mathematician. He conceived the project of explaining the Old Testament through a connection between the history of the Jews and Chinese, and wrote a long commentary on the book of Esther in pursuance of that object. Extracts from this, and a large number of his dissertations, are contained, with those of Amiot, in the *Mémoires concernant les Chinois*.

CIBRARIO, Luigi, an Italian statesman and historian, born in Turin, Feb. 23, 1802, died at Salo in the province of Brescia, Oct. 1, 1870. He took his degree as doctor of civil and canon law in 1824, and devoted himself during a great portion of his life to historical research. He was for many years in the service of King Charles Albert of Sardinia, and was sent by him on diplomatic missions to Switzerland, France, and Austria. In 1848 he took possession of Venice as commissioner of Sardinia, and the same year became a member of the senate. After the abdication of Charles Albert in 1849, he was sent to Oporto to endeavor to induce the king to return, and wrote an account of that unsuccessful mission. He became a member of Victor Emanuel's cabinet in 1852, as minister of finance, and in 1855 was minister of foreign affairs under Cavour, which post he held during the Crimean war. In 1860 he became minister of state, and in the following year received the title of count. His historical works include histories of Turin, Geneva, and the kingdom of Savoy, notices of the princes of Savoy, a life of Charles Albert, and an account of the political economy of the middle ages. He also published several volumes of novels, and editions of Petrarch and other eminent Italian writers.

CICACOLE, or Chicacole, a town, fort, and cantonment of British India, presidency of Madras, in an ancient district of the same name, one of the five Northern Circars, 110 m. S. W. of Ganjam and 445 m. N. E. of Madras; pop. about 12,800. The town, situated on the left bank of the Naglaudee, a few miles above its mouth in the bay of Bengal, is a straggling place with narrow crooked streets and houses built of mud. There are several mosques, one of high reputed sanctity, and a number of bazaars of considerable importance. The manufactures are chiefly of common cotton goods and of fine muslins, the latter rivalling

those of Dacca in Bengal. The fort, N. of the town, is completely dismantled, its walls and ditch being hardly traceable. It contains the regimental offices. The encampment is about 100 yards S. E. of the fort. At the corner of the parade ground is a small church, and the London missionary society has a school within the town, where English is taught. There are also several native schools.

CICERO, Marcus Tullius, a Roman orator, statesman, and philosopher, born at Arpinum, Jan. 3, 106 B. C., assassinated Dec. 7, 43 B. C. He belonged to an equestrian family, and with his brother Quintus was educated at Rome by eminent teachers, among whom was the poet Archias. At the age of 17 he attached himself to Quintus Mucius Scaevola, the augur and pontifex, to study law and politics; he studied the Epicurean philosophy under Phædrus. The social war interrupted these pursuits, and he was obliged to serve in the army; but at its close he returned to his studies. He was a pupil of Philo the Academic, and became familiar with the Stoic philosophy under Diodotus, who lived in his house; in rhetoric his teacher was Molo of Rhodes. He made his first appearance as an orator in a civil suit; but his infirm health stopped him at the beginning of his career, and for its restoration he travelled in Greece and Asia in 79-78. At Athens he became acquainted with Atticus, a Roman knight, whose friendship he enjoyed until his death; at Rhodes he met Molo, and again placed himself under his tutorship, overcoming his violent manner of speaking, which his feeble frame was unable to bear. He returned to Rome refreshed in body and mind, and from this time may be dated his public career. In 75 he was *quæstor* under Sextus Peducaeus, prætor of Sicily, where he ruled with the greatest justice, beloved by all the people. In 70 he brought his accusation against Verres for extortion in Sicily. In 69 he was *ædile*, in 66 prætor, and in 63 consul. His consulship has been rendered immortal by the suppression of Catiline's conspiracy, for which he was styled *pater patriæ*. But here he laid the foundation for his own destruction. Hatred, envy, and his own boasting had made him many enemies, especially Clodius, whom he had mortally offended, and, unable to endure the shocks of party strife, he left Rome in 58; the enraged people burned and destroyed his house and villas. At this period Cicero yielded to the most unmanly despair, and showed himself of a weak and timorous disposition. In 57, however, his party regained power, and he returned with great joy, Lentulus and Spinther being consuls, and Milo, the opposer of Clodius, tribune. The forum and senate became again the theatres of his actions for many years. In 53 he was chosen into the college of augurs, and in 52 he defended Milo. In 51 he was proconsul of Cilicia in Asia Minor, which he governed with the strictest justice; in this

province he proved his military talents in repelling and conquering the enemy, but was displeased on his return to Rome in not obtaining a triumph. At this time the disputes between Cæsar and Pompey were at their height, and Cicero joined the latter; yet after the defeat of Pompey at Pharsalia (48), he came to Rome at the invitation of Cæsar. He then devoted himself to philosophy until the death of Cæsar in 44; after this he again mingled in the political strife of the times, and in his 14 philippics attempted the ruin of Antony. But his enemy was too powerful, and when the new triumvirs, Antony, Lepidus, and Octavius, made out the list for their proscription, Cicero was upon it, among the most prominent of the intended victims. Octavius permitted him to be slain by Antony to gratify his revenge, though he might have prevented it by his personal authority. He fled from his Tusculan villa, where he was residing, but was overtaken by the hired assassins of the triumvirate near Formiæ, and killed in his litter, meeting death with more bravery than he had shown in anticipating it. It happened that the man who severed his head from his body, the leader of the assassins, was one whom Cicero had successfully defended. Cicero was married for the first time in 77, just before his travels, to Terentia, by whom he had a son, Marcus, and a daughter, Tullia; he was divorced from her in 46, and married Publilia, a rich lady, from whom he was divorced on account of her rejoicing at the death of her stepmother. His son Marcus was honored by Augustus, but was according to all accounts a worthless and intemperate man, in every way unworthy of the noble philosophy addressed to him by his father in his *De Officiis*. Cicero's brother Quintus died about the time of the orator's assassination from the persecution of Antony. In 1544 a monument was discovered in the island of Zante, supposed to have been the tomb of Cicero, but it is generally believed that he was buried in his academic villa in Italy.—In person Cicero was tall and slender, feeble, but strengthened by temperate habits; in his disposition he was amiable and cheerful, firmly attached to his family and friends, generous in the extreme, and seldom influenced by malice or envy. He was very rich, but his riches were of his own acquiring; he was neither extravagant nor avaricious. He possessed no fewer than 14 villas in different parts of Italy, whither he retired to devote himself to study and meditation. The most celebrated was the one called Puteolanum, on the site of the modern Pozzuoli, also named after the academy at Athens; after his death it fell into the hands of strangers, and among others of the emperor Hadrian, who changed it into a palace, in which he died. The virtues of Cicero far outnumbered his vices and foibles; he was undoubtedly deficient in prudence, decision, and fortitude, but the chief charge against him has been vanity. The love of ap-

probation was the mainspring of his best as well as some of his least noble deeds; his courage would have been insufficient, without this aid, to lead him to enter upon his most difficult tasks, especially the suppression of Catiline's conspiracy. This vanity led him into his worst errors. As a statesman he dearly loved his country, and throughout his whole political career he was a true patriot. As a scholar his learning was remarkable not so much for originality as for extent; his reading embraced every department of knowledge; he attempted almost every branch of literature, and with success; but eloquence was the field in which he best displayed his ability. He possessed some poetic talent, but did not, as far as is known, much cultivate it. Of his merit as a historian no judgment can be formed, as none of his works of this class are extant. In philosophy he was a sound thinker, and a well-read and acute reasoner; one of his great merits in this department is the beautiful extension of the imperfect ideas of others in a language peculiarly his own. In law he displays much knowledge, and to the moderns he is a very important authority in regard to Roman jurisprudence, many points of which are discussed in his orations.—The works of Cicero may be divided into four classes: rhetorical, oratorical, epistolary, and philosophical; many of the last three classes, and all of his poetical writings, are lost. It may appear strange that few of the writers of the Augustan age mention the works of Cicero; but this is easily accounted for when we consider the peculiar circumstances of their situation in regard to Augustus, who was somewhat jealous of his newly acquired power. Livy and Asinius Pollio give unqualified praise to Cicero; and in the subsequent periods of Roman literature he was much praised by all; even the Latin fathers extol him, and abound in quotations from his works. His literary merits are of the highest class; his Latin is of the purest; his style harmonious and pleasing, neither too ornamental nor too plain. In the middle ages Cicero was absolutely idolized; there was a class of writers whose aim it was to acquire the language of Cicero, and who would hear or speak of nothing but him; they carried their whim so far as to style themselves "Ciceronians," among whom were many of the learned men of the times. Erasmus at last opposed this "Ciceromania," not because he did not like Cicero, but in order to keep the admiration of him within proper limits. The *editio princeps* of his works was published at Milan, 1498; the best edition is perhaps that of Gronovius, at Leyden, 1692; others are those of Ernesti, 1777; of Olivet, Paris, 1749; and of Orelli, Zürich, 1826-'46. Cicero's rhetorical works are the result of his Greek instruction, diligent study, and long experience. He defines eloquence as "the art of gaining others to our opinion;" a definition which, as Quintilian says, is rather too limited. The first work in the

class of rhetoric usually contained in the writings of Cicero does not belong to him; it is entitled *Rhetoricorum ad C. Herennium libri quatuor*. The opinion that this belonged to Cicero arose from quotations in the Latin fathers as his; Quintilian quotes similar passages as coming from Cornificius. Leaving Cicero out of the question, opinions vary as to the writer; some ascribe it to Tullius, others to Tiro, and some to Cicero's son Marcus. The second work is *De Inventione Rhetorica*, in two books, written in his youth; it is considered of no importance even by Cicero himself; it seems to be notes of lectures, and this and the preceding may be merely minutes taken by two individuals of the same course of lectures. The third is *De Oratore libri tres ad Quintum Fratrem*, written about the year 55; it is a dialogue between distinguished orators of the age preceding his own, when Crassus and Antonius flourished; his object was to set up his ideal of an orator, and to prescribe the course of education; he is not so lively as Plato, but yet is very pleasing. He attached some value to it, and it is the more interesting as it shows his own manner of education; it is written with great art, ease, and grace, and abounds in beautiful digressions, as that on wit, in the second book. It is one of the most perfect of his works. The fourth is *Brutus, sive de Claris Oratoribus*, written in 46, after his return from Pharsalia; this is also in the form of a dialogue, and is very important as a history of Roman eloquence; it has also a short preface on the eloquence of Greece. The fifth is *Orator, sive de Optimo Dicendi Genere*, addressed to Brutus, in which he delineates the perfect orator. The sixth is *Topica*, addressed to Trebatius, published in July, 44, just after the death of Cæsar; it was written on a journey to Rhegium, in compliance with the request of Trebatius that he would make him a manual on legal arguments; it is an abstract of the "Topics" of Aristotle, which Trebatius was unable to comprehend. This is the same Trebatius whom Horace consults as to whether he should write satires or not. The seventh is *De Partitione Oratoria*, a dialogue between Cicero and his son; it was written about 46, and is a manual of rhetoric, treating of the doctrine of arrangement according to rhetorical rules. The genuineness of this has been questioned, probably on account of its numerous defects. The last is *De Optimo Genere Oratorum*, a small work, a preface to translations of two orations of Demosthenes and Æschines; he had been charged with belonging to the Asiatic school, and he here vindicates himself, and shows the best kind of eloquence.—The second class of Cicero's works consists of his orations; many of these have not come down to us, either because they were not delivered after they were prepared, or because they were not written down until a long time after they were delivered; many fragments of single orations leave no doubt of the excellency of those which have been lost.

In his orations Cicero discusses matters of state and of private life, and affords invaluable sources of information regarding the public and domestic usages of Rome. His 1st oration in public was *Pro P. Quintio*, in which he defeated his rival Hortensius, delivered in September, 81 B. C. The 2d, *Pro Sexto Roscio Amerino*; this was his first criminal case, in which he refutes the charge of murder brought against his client, in the year 80; Cicero displayed considerable courage in the management of this case, as in it he was opposed to the dictator Sulla, and had to deal with many delicate political relations; he gained his case, and with it great fame. The 3d, *Pro Q. Roscio Comado*, delivered in 76; in this he defends the great actor, who had been sued for debt; the beginning of this oration is lost. The 4th, *In Q. Cæciliam*, a kind of preface to the accusation of Verres, in the year 70; Cæcilius claimed the right to accuse Verres. The 5th, *In Verrem*, divided into two parts: the first *actio* is the introduction, in which he brings forward the proofs of Verres's guilt, in one oration; the second *actio* consists of several orations, in which he gives an account of Verres's crimes; these were not delivered, as the accused withdrew his cause after the first *actio*, and went into voluntary exile; Cicero, however, published them. The 6th, *Pro M. Fonteio*, in the year 69, in which he defends the accused in a charge of extortion, by exciting pity for his client, and odium against his accusers; the first part is wanting, and of the rest there is only one MS. at Rome. The 7th, *Pro Lege Manilia*, in 66, delivered before the people in favor of the motion of Manilius that the command of the Mithridatic war should be given to Pompey; this is a famous and beautiful oration. The 8th, *Pro Aulo Cluentio Avito*, in 66, by which he obtained the acquittal of the defendant, who had been accused of poisoning his father-in-law. The 9th, *De Lege Agraria in Servilium Rullum Orationes tres*, in 63; the intention of Cicero was to defeat the plans of Rullus, who wished to sell the public lands for the benefit of the plebeians; this oration is very important, as it treats of the administration of the Roman public lands, but for this very reason it is difficult to understand. The 10th, *Pro C. Rabirio*, delivered before the people; this was a case of murder, and the duumviri chosen had been appointed in an unusual manner; after his sentence the defendant, as was the custom, appealed; this oration treats of prerogatives; Niebuhr has made some discoveries concerning it in the Vatican. The 11th, consisting of four orations, *In Catilinam*, in 63, famous for their eloquence, and historically of great importance, as showing the state of the times; these orations have had innumerable commentators, and are familiar to every Latin scholar. The 12th, *Pro L. Murena*, in 63; he had been accused of using improper means to gain the consulship in opposition to Servius Sulpicius Rufus; this also gives a vivid picture of the times. In this oration Cicero is

very severe against the profession of law, to which Rufus belonged; his remarks must be received with considerable allowance, as it was the custom then, as now, for an orator to attempt to prejudice an audience against his opponent by digressions upon such topics as his profession, and by allusions to various matters foreign to the case in hand; by substituting a vacillating jury for a fickle populace, this case might very well have been argued before a supreme court of the 19th century. The 13th, *Pro C. Cornelio Sulla*, who had been accused of taking a part in Catiline's conspiracy. The 14th, *Pro L. Valerio Flacco*, in 59; he had just returned from Asia, which he had governed as proprætor; he was defended with the greater readiness, as Flaccus was prætor when Cicero was consul in 63. The 15th, *Pro Aulo Licinio Archia*, the teacher of Cicero; his title to the rights of citizenship had been called in question, and Cicero maintains it with consummate skill, fine language, and excellent method; although the genuineness of this oration has been doubted by some, who find in it marks of carelessness and levity. The 16th consists of four orations, *Ad Quirites, In Senatu, Pro Domo sua ad Pontifices, De Haruspicum Responsis*, in 57; these relate to his domestic affairs; their authenticity was called in question by Markland, an English scholar, in 1745, who styles them mere rhetorical exercises; this opinion has been opposed with great eagerness by Ross, Gesner, and Wolf. The 17th, *Pro Cneio Plancio*, in 55; he had been accused of using improper means to obtain the prætorship, and was defended by Cicero, whom he had hospitably received when in exile; this oration was much altered after its delivery. The 18th, *Pro Publio Sextio*, in 56; he had also treated Cicero kindly when in exile, and was a bitter enemy of Clodius. The 19th, *In Vatinius*; this is connected with the last, and is an examination of Vatinius, a witness against Sextius. The 20th, *Pro M. Cælio Rufo*, in 56; he was accused of murder. The 21st, *De Provinciis Consularibus*, in 56. The 22d, *Pro L. Cornelio Balbo*, in 56; his title to the rights of citizenship, presented to him by Pompey, was called in question. The 23d, *In L. Calpurnium Pisonem*, in 55, delivered before the senate; this is a reply to Piso, who, when governor of Macedonia, had been recalled through the influence of Cicero; it is the most severe and bitter of all his orations, displaying the whole political career and secret actions of Piso; the beginning is lost. The 24th, *Pro Tito Annio Milone*, who was accused of the murder of Clodius, delivered in 52, but written down much later; though unsuccessful, this is considered by many one of his best speeches; Cicero, moreover, took a personal interest in the case for political reasons; there is a part of a commentary upon it by Aconius. The 25th, *Pro C. Rabirio Posthumo*, in 54; he was accused of being connected with Gabinius in the mismanagement in Syria; Cicero has been much

blamed for pleading this case. The 26th, *Pro M. Marcello*, in 47, before the senate; this was to obtain the recall of Marcellus from exile, and was the first delivered after Cæsar became the head of the state; it was written down long after it was delivered, yet it is one of his best for its style, language, and method; it had always passed for one of Cicero's best orations until the time of Wolf, who denied that he wrote it at all, and published a pamphlet to prove that it is only a rhetorical performance at the schools; this pamphlet is perhaps one of the best specimens of modern Latin extant; the statement met with many opponents, especially Jacob, who would not give up the opinion of centuries so easily. The 27th, *Pro Q. Ligario*, in 46; he was a partisan of Pompey, and was successfully defended by Cicero against Tubero. The 28th, *Pro Deiotaro*, the tetrarch of Galatia, and the friend of Pompey, who was accused of conspiring to murder Cæsar, in 45; he was defended with success. The 29th, *Orationes quatuordecim in M. Antonium*, sometimes called the "Philippics," in imitation of those of Demosthenes against Philip of Macedon; written between September, 44, and May, 43, and designed to defeat the ambitious schemes of Antony; the second, which is the best, was not delivered; it is a reply to an attack by Antony in the senate. These orations may be considered as the cause of Cicero's murder, as they kindled a flame of vengeance in the breast of Antony which nothing but his blood could extinguish; the language is forcible, pure, and elegant; besides exposing the public and private life of Antony, they afford important materials for the history of that troubled period. These are all the orations of Cicero which we have nearly or quite complete; there are some imperfect ones, of which may be mentioned the *Commentarii*, said to be in 13 books; they were probably notes, which he used when he afterward wrote out his speeches; the loss of these is much to be regretted; *Pro C. Cornelio*; *Pro Toga Candida adversus Competitores*; *Pro M. Emilio Scauro*; *De L. Othone*, to allay the tumult which had arisen on account of the division of the seats at the theatre. In connection with the orations of Cicero, should be mentioned those by whom new fragments have been discovered; the most celebrated is Angelo Mai, for many years the librarian of the Vatican; others are Peyron and Niebuhr. As an orator, Cicero is without doubt the greatest his country ever produced; even in his own time he was placed by the side of Demosthenes. He exhibits the happy medium between the dryness of Demosthenes and the exuberance of the Asiatic school; no ancient orator could so easily and naturally turn the feelings of an audience in any desired direction. With Cicero Roman eloquence attained its highest excellence, and after him rapidly declined; the condition of the state did not permit its exercise for any but political purposes; it fell into the hands of rhetoricians,

who cultivated it only as tending to strengthen the mental powers; it became a written eloquence, composed in the schools; but this kept up the interest in it for a short time only. Cicero has had hosts of commentators, the oldest and best of whom is Q. Asconius Pedianus, a native of Padua; he wrote commentaries on these orations, A. D. 41, for the use of his sons; the fragments preserved show the great value of this work; they relate to nine orations, and were discovered by Poggio in St. Gall; some others were found in the Ambrosian library at Milan.—Cicero was also chief among the Roman philosophers. He was first an Epicurean, and the disciple of Phædrus; he afterward paid great attention to the Academic philosophy, on account of its excellent system of philosophical and rhetorical education; finally he devoted himself to the Stoic school, yet even this, like the rest of his countrymen, he regarded only as a means of education, and not as a rule of life. He discontinued his philosophical pursuits when he entered upon public duties; but after the downfall of the republic he again devoted himself to these studies, and wrote in rapid succession his works on philosophic subjects. His object was to make his countrymen familiar with the philosophy of Greece; the reader must not, therefore, expect to find in his works anything new. Cicero was for a long time considered authority on matters of philosophy, instead of the Greek originals; but after the revival of learning in the middle ages, more attention was directed to the latter. On abstruse subjects, such as God, the soul, &c., he never expresses himself with certainty, but always speaks in the most guarded manner; he has, therefore, often been censured for opinions that he probably never entertained, as, for instance, atheism. He seems to have written on the Academic principle, "that there is no certain knowledge." In his manner of treating his subjects he follows Plato, but in his morals he is decidedly a disciple of Zeno the Stoic. His philosophical works, in the order in which they were written, are the following: *De Republica libri sex ad Atticum*, composed at his villa near Cumæ, 54 B. C.; this is a dialogue between Scipio, Lælius, and others, on "What is the best form of a state?" The scene is laid about 129 B. C.; a very interesting time, when the country was convulsed by the disturbances of the Gracchi, whose movements furnish many illustrations in the course of the work; the book closes with the *Somnium Scipionis*. It was lost for several centuries, with the exception of the "Dream of Scipio," which was saved by means of a commentary upon it by Macrobius; there were a few fragments, too, found in the Christian fathers. Mai discovered a palimpsest, the upper writing of which was a book of the Psalms, and the lower the *De Republica*; similar strange fellowships are not uncommon in the palimpsests; by this most of the first and second books have been recovered. The next work is *De Legibus libri tres*; the genuineness

of this has been questioned from the fact that in another book, *De Divinatione*, Cicero enumerates all his works, and that this is not among them; but this reason is insufficient, as the present book is unfinished, and of course would not have been included in a list of his writings; the second and third books were probably never revised; it was written soon after the death of Clodius, when Cicero was chosen into the college of augurs, in 53; it was not published until after his death; in this work Cicero shows that there is in man a natural principle to make and respect laws; Macrobius quotes a fifth book. The next is *Academica*, a curiosity on account of the changes it has undergone; it was originally written in two books; he afterward rewrote it. It treats of the old academy of Socrates and the new of Carneades and Philo; it also contains a sketch of the system of Arcesilaus, or the middle academy. We have much of the first book of the second edition. It was written in 45, and is perhaps as good a book as any by which to ascertain Cicero's real opinions, always a difficult task. *De Finibus Bonorum et Malorum libri quinque*, addressed to Brutus, was written also in 45; it consists of dialogues containing the views of the most celebrated Greeks on this subject; in the first book Torquatus gives the view of Epicurus, and in the second Cicero refutes it; in the third and fourth Cato and himself state the opinions of the Stoics; and in the fifth Piso gives the views of the old academy. It is very important in literary history. *Tusculanarum Disputationum libri quinque ad Brutum* appeared in 44; it was written with great rapidity, and bears marks of carelessness purposely introduced to give it an air of ease; it consists of dialogues in his own villa upon various practical subjects; the first book is on the contempt of death; the second on firmness and constancy in suffering; the third on the means of alleviating suffering; the fourth on the passions; the fifth on virtue as the means of happiness; the last is by far the best; a good edition is the old English one by Davis. *De Natura Deorum libri tres ad Brutum* was written in April, 44; in this dialogue are expressed the opinions of the Epicureans, Stoics, and Academics on this subject, but as usual it is difficult to get at his own opinions; he seems to agree with Plato and the Academics; his object was to introduce better views on this important subject. *De Divinatione libri duo* was written immediately after the last, and is connected with it; in the first book his brother Quintus states the opinions of the Stoics in favor of divination, and in the second Cicero refutes them. *De Fato* is intimately connected with the preceding two; its intention is to overthrow the Stoic doctrine of fate, and to establish that of free will; it is very imperfect, the first and last portions being lost, and the text of the rest quite unsettled. *De Senectute*, addressed to Atticus, was written in the country; it de-

scribes the peculiarities of old age, and shows that they should be looked upon without uncharitableness, as it is the lot of all who outlive friends and kindred; it is mostly a soliloquy, and so charming that we are almost persuaded to long for old age as the most enviable portion of human life. *De Amicitia*, addressed also to Atticus, was composed soon after; Lælius is the chief character, and gives utterance to the most exalted sentiments. *De Officiis libri tres*, written in 44 to his son Marcus, abounds in noble sentiments, although not quite coming up to the theoretical morality of modern times. *Paradoxa Stoica*, in six books, addressed to Brutus, treats of the dogmas of the Stoics. Cicero wrote several other philosophical works, wholly or nearly lost; he himself alludes to several, as: a Latin paraphrase of the *Timæus* of Plato; *De Gloria libri duo*, addressed to Atticus, of which we have a few fragments; there is a report that Petrarch had a MS. of this work; *Economicorum libri duo*, in imitation of Xenophon, laying down the duties of the master of a family; Columella made some use of this; it was written when he was very young, about 84 B. C.; a translation of the works of Protagoras, a follower of Democritus; *Laus Catonis*, in praise of Cato Uticensis, in 46; this was received with such approbation that Cæsar, fearing its influence, wrote *Anti Cato*, in answer to it; only a few fragments are preserved; *De Philosophia*, in which he recommends the study of philosophy, and defends it against several objections; *Consolatio*, written on the death of his daughter Tullia; *Liber de suis Consiliis*, written in the year of his consulship, 63 B. C.; *Chorographia*, a geographical work. Cicero was also a didactic poet; he translated the *Phenomena* of Aratus, a part of which has come down to us.—There have been many lives of Cicero; there was one written by his freedman Tiro, and one by Nepos, which are lost; we have one by Aurelius Victor, and another by Plutarch, besides many facts and data collected from his own writings, especially his letters. Among modern biographies that of Middleton (London, 1741; Bohn's edition, 1854) has gained much fame; but it is a panegyric of such extravagance as to make a large proportion of its statements untrustworthy. Forsyth's "Life of Cicero" (London, 1864) is an excellent work; and a very good biography of Cicero is to be found in vol. v. of Drumann's *Geschichte Roms*. Mommsen, in his *Römische Geschichte*, handles him very severely. A good English translation of the works of Cicero (with the exception of the "Letters") is published in Bohn's "Classical Library." The "Letters" have been translated by Melmoth and Heberden.

CICOGNA, Emmanuel Antonio, an Italian historian, born in Venice, Jan. 17, 1789, died there, Feb. 22, 1868. He published numerous works relating to the history of Venice, the most important of which is *Delle iscrizioni Veneziane raccolte ed illustrate* (21 parts).

CICUTA, a deadly genus of plants belonging to the natural order *umbellifera*, with dissected leaves, white flowers, and subglobose fruit contracted at the sides. *C. maculata* (water hemlock, spotted cowbane, musquash root, or beaver poison) is common in swamps in the United States. The root, which somewhat resembles a parsnip in taste and smell, has given rise to cases of fatal poisoning. The seeds contain an alkaloid, supposed to be identical with conia. It has been used in the treatment of nervous headaches. Poisoning by it should be treated with emetics and stimulants. A full account of the plant may be found in Bigelow's "Medical Botany," i., 125, and an analysis of its seeds in the "American Journal of Pharmacy," vol. xxvii., p. 294. *C. virosa* (cowbane or water hemlock), the European species, an acid narcotic, produces tetanic convulsions, and has proved fatal to both men and animals. It has little or no use in medicine. (See **CONIUM**.)

CID, **The**, or **Cid Campeador** (lord champion), a popular hero of Spain, whose real name was RUY or RODRIGO DIAZ, born at the castle of Bivar, near Burgos, about 1040, died at Valencia in 1099. He figures prominently in early Spanish literature, but his genuine exploits are so mixed up with fictions that it is impossible to ascertain his real history. According to the most consistent accounts, he belonged to a powerful family, and became standard-bearer and commander of the royal troops to Sancho II., king of Leon and Castile. At the siege of Zamora the king was treacherously slain, and his brother Alfonso, the next heir to the throne, was suspected of having been privy to the deed. Diaz compelled Alfonso to declare his innocence by an oath, with terrible maledictions in case of falsehood, before he would permit him to occupy the throne. His life was spent in combat with the Moors, to whom he became a terror on account of his constant success. The designation *el Seid*, corrupted to Cid in Spanish, was given to him by the Moors in acknowledgment of his prowess, while the Spaniards whom he protected and avenged called him *el Campeador*, the champion; and finally the two epithets combined were almost universally applied to him. He captured Valencia about five years before his death, and established himself as its ruler. His wife held the place about three years after he died, and was then forced to fly to Castile, where she died in 1104. He had a son, who was killed by the Moors in battle, and two daughters, one of whom was married to the count of Barcelona and the other to the prince of Navarre. The exploits of the Cid soon became the subject of poetry and romance, and he became in the popular mind the pattern of a Christian warrior, invincible in battle and unblemished in character. Fictions were mingled with his actual achievements, until his identity was well nigh lost; and some writers have even contended that he was only a myth. The

"Poem of the Cid," composed about the year 1200, is one of the earliest and most vigorous specimens of Spanish verse. It contains nearly 4,000 lines, and professes to give a continuous account of the doings of its hero. The author is often spoken of as the Homer of Spain, but his name is unknown. The "Chronicle of the Cid," a prose production of the 13th century, is also of unknown origin. There are three editions of this, dated in 1541, 1552, and 1593. Besides these there are numerous romances and ballads on the same subject, many of which have been translated into English by Lockhart. A complete collection in the original is contained in Augustin Duran's *Romancero general*. The old "Poem of the Cid" was originally published by Sanchez in the first volume of his *Poesias castellanas anteriores al siglo XV*. (4 vols. 8vo, Madrid, 1779-'90), and reprinted by Ochoa (8vo, Paris, 1842). Excellent translations from it were made by Herder in German, and by J. Hookham Frere in English. Southey's "Chronicle of the Cid" is made up of free versions and compositions from the old poem, the prose chronicle, the ballads, and the general chronicles of Spain. It furnishes the stories and traditions in a very pleasing form. Of the dramas founded on this romantic subject Corneille's *Cid* is the best known.

CIDER, the expressed juice of apples, either fermented or unfermented. Its quality depends upon that of the fruit from which it is made. Vinous fermentation converts the sugar contained in the juice into alcohol. The specific gravity, therefore, of new or unfermented cider, being very nearly in proportion to the amount of sugar, will indicate to the manufacturer the strength which he may be able to give to his cider. The apples should be ripe and well mellowed, to diminish the quantity of gum, and develop the greatest possible quantity of sugar as well as the highest flavor; and they should also be well crushed, that the

Cider Mill.

pulp may be immediately put to press, before fermentation commences. A good form of mill, which has long been in use, consists of two longitudinally grooved wooden cylinders

turned on vertical axes by a horizontal lever, and firmly supported upon a vat into which the pulp falls. The pressing may be conveniently performed by a common screw press, in which

Cider Press.

the pulp is placed in layers called cheeses, folded in straw. The juice is received in a tub or vat, and is carefully strained before being put in barrels. The fermentation of cider is conducted in the same manner as that of wine, and several varieties may be produced from different apples, and by various methods. It may be kept in barrels or bottles, like wine. The new or sweet cider is sometimes boiled to a thin sirup, which may be preserved in tight bottles for a long time, and conveniently used for preserving, and for preparing condiments and other articles of food.

CIENFUEGOS, a city of Cuba, capital of a jurisdiction in the department of the Centre, situated on the S. side of the island, on the bay of Jagua, 130 m. S. E. of Havana; lat. 22° 15' N., lon. 80° 32' W.; pop. about 10,000. The harbor, which is capacious and safe, is defended by the fort of Los Angeles. The city is the most beautiful on the island. The streets are wide and straight, and many of the houses are surrounded by gardens. Among the principal buildings are a theatre, a number of churches, and several public schools. Railways connect the town with Cardenas and Sagua la Grande, on the N. coast. It has two daily newspapers and a considerable local trade. The chief exports are sugar, wax, and timber. Cienfuegos was founded about 1813, and was named from the captain general of Cuba at that time.

CIENFUEGOS, Nicasio Alvarez de, a Spanish poet and dramatist, born in Madrid, Dec. 14, 1764, died at Orthez, France, in July, 1809. He was educated at Salamanca, and in 1798 published a volume of miscellaneous poems. He also wrote pieces for the stage, successful in their day, but now neglected, including *Pitaco*, *Idomeneo*, *La condesa de Castilla*, and *Zoraida*. He became the editor of the government gazette

in 1798; and on the occupation of Madrid by the French in 1808 he so offended Murat that he was condemned to death for trying to incite an insurrection. The sentence was commuted to banishment to France, but he survived only a few days after reaching the place of his imprisonment.

CIEZA, a town of Spain, on the Segura, in the province and 24 m. N. W. of Murcia; pop. about 8,000. It has a workhouse, a public granary, and manufactures of coarse linen.

CIGAR (Span. *cigarro*), a cylindrical roll of tobacco for smoking, usually pointed at one end and truncated at the other, made of the leaf divested of stems and enveloped tightly in a single leaf. A diminutive cigar (*cigarrito*) is made of chopped tobacco wrapped in unsized paper. In the East Indies a cigar called cheroot is made, having the form of the frustum of a slender cone. The best tobacco for making cigars grows in the western end of the island of Cuba, and is known as the *vuelta abajo*, the plant most in vogue there being the *nicotium repanda*. That which is raised east of Havana is called *vuelta arriba*, and is of an inferior quality. The most noted *vega* or plantation is situated near the town of Santiago de Cuba, and is called Yara. The *vuelta abajo* is divided into five classes: 1, *calidad* or *libra*, noted for its good color, flavor, elasticity, and perfection of the leaves, rendering it desirable for wrappers; 2, *yajuriado principal*, or firsts, which has less flavor and is usually of a lighter color; this also is suitable for wrappers; 3, *segundas*, or seconds, a shade poorer in every particular, but good for fillings and inferior wrappers; 4, *terceras*, or thirds, which are generally employed for fillings; 5, *cuartas*, or fourths, also employed for fillings. The choicest tobacco is that raised on the banks of the rivers which are periodically overflowed. The varieties are called *Lo Río*, *Río Hondo*, and *Pinar del Río*, and the tobacco is distinguished from all others by a fine sand which is found in the creases of the leaves. The island of Trinidad also produces a very superior article of the same sort. In Mexico a large quantity is raised, but entirely for home consumption, its exportation being forbidden. The tobacco used for manufacturing the Manila cheroots is the produce of the island of Luzon, and is considered nearly equal to that of Cuba. A very superior quality is also raised in the province of Kadoe in Java, in a naturally rich soil, alternately with crops of rice, and without manure. In western Asia, that produced at Latakiah in Syria, and that of Shiraz in Persia, are most highly prized. In the province of Gelderland, Holland, about 2,000,000 lbs. are produced, the larger portion of which is purchased by the French government. In Connecticut also a very superior article for the exterior wrapper is grown, and much of it shipped to Cuba, the remainder being employed mostly in New York for the same purpose. These peculiar varieties are valuable on account of the fineness

of the leaf and its freedom from thick fibres. Many experiments have been made in transplanting the seed of the Spanish tobacco to various parts of the world, particularly to the middle states of the American Union, and in some cases with marked success. It has been found necessary, however, to renew the seed every two years, as after that period the plant loses its original odor and flavor.—Although cigars are of very ancient origin in the West Indies, they were not generally known in Europe until the beginning of the 19th century. In fact, of all the various works on gastronomy and the pleasures of the table, written and published from 1800 to 1815, not one speaks of this adjunct of a good dinner. Even Brillat-Savarin, in his *Physiologie du goût*, entirely ignores tobacco and all its distractions and charms.—As the best tobacco grows in Cuba, so also the best cigars are made there. Previous to 1820 the manufacture was a government monopoly, and since that period the trade has been open; but so great is the demand that very little competition exists among the manufacturers. The brands affixed to Havana cigars are entirely arbitrary, and are rarely continued for any great length of time. In the Philippines, the tobacco and its manufacture are a close government monopoly. The best quality is produced in the northern parts of the island of Luzon. It is raised under the supervision of government officials, and is taken from the growers directly, a liberal price being paid for it. That produced in the southern group known as the Visayas is of an inferior quality, and is sold to merchants holding a permit “to purchase at the shipping ports, and transport to Manila for sale to the government.” The Luzon tobacco is classed and paid for by the government at the ports whence it is shipped to Manila; but the merchants buying in the southern islands transport it to Manila at their own risk, and then take the chances of its being classified much lower than they have purchased it. Being under heavy bonds to deliver all they purchase at the government storehouses, but little smuggling is carried on, the risk being greater than the gain. There are three factories for manufacturing cigars—one in Manila, where 7,000 females and 1,200 males are employed; one in Cavité, in which 5,000 operatives, mostly females, are engaged; and one in Malabon, which gives employment to about 2,000 more, also females. These operatives are paid by the piece. It is supposed by many, in consequence of the soporific effect produced by using cheroots, that opium is employed in preparing the tobacco in these factories, which is an error, no admixture of any kind being permitted. A very large amount of tobacco of an inferior quality is consumed on the islands, the better kinds being generally exported.—In every large city throughout the United States immense numbers of persons are engaged in this manufacture. Great skill has been attained in the American factories in ma-

king cigars; so much so that it is difficult to discriminate between the genuine and the spurious article, excepting by trial, and even then in some cases it requires the nicest taste to detect the difference. Many persons engaged in this business import tobacco from Cuba, employ the Connecticut leaf for wrappers, and produce an article equal in appearance to the very best made in Havana. In Bremen and Hamburg immense numbers of cigars are made, and shipped to every point of the habitable globe at very low prices. The city of Bremen, which was among the first to adopt this branch of industry, has now become one of the first markets in the world for the sale of cigars. In Spain, the manufactories at Seville have attained a high European reputation, and, being protected by government, very nearly monopolize the trade. The employment of female labor in the manipulation of this article is one of its noticeable features; and it is work particularly adapted to women, requiring great dexterity and peculiar delicacy in the handling.—The consumption of cigars extends all over the globe, and increases yearly in a wonderful ratio. The number of cigars exported from Havana in 1872 was 229,087,545; of cigarettes, 19,344,707. In 1873, to April 18, the numbers were 78,655,231 and 5,501,769 respectively. The annual home consumption of cigars in Cuba was estimated some years ago, in a consular report, at nearly 1,500,000,000.

CIGNANI, Carlo, an Italian painter, born in Bologna in 1628, died at Forlì, Sept. 6, 1719. He was a pupil of Albano, and passed a number of years at Rome, Florence, and Parma, studying the works of Raphael and Correggio. On the establishment of the Clementine academy by Pope Clement XI. in 1708, he was appointed the director. Among his principal works are the "Assumption of the Virgin," an immense fresco in the dome of a church at Forlì, which occupied him 20 years; the "Entry of Pope Paul III. into Bologna," "Francis I. healing the Lepers," the "Nativity," the "Virgin and Infant enthroned," four subjects from sacred history in ovals, supported by angels (all at Bologna), "Charity," and the "Chastity of Joseph."

CIGNAROLI, Giovanni Bettino, an Italian painter, born near Verona in 1706, died in 1772. His best works are in the cathedrals of Pisa, Bergamo, Mantua, and in the churches of his native city and of Ferrara. Chief among them are the "Flight into Egypt," the "Holy Trinity," the "Descent from the Cross," the "Transfiguration," and the "Death of St. Joseph," in style modelled on the works of Correggio and Guido. He wrote with taste on various subjects.

CILIA (Lat. *cilium*, an eyelash), minute, hair-like, constantly moving organs on the surface of animal and vegetable tissues. They are abundantly found in all the individuals belonging to the class of microscopical animalcules, the most minute and the lowest in

organization of all created beings. Examined by the microscope, these remarkably delicate organs are seen to be in incessant vibratory action, and hence they are usually described as vibratile cilia. In this lowly class of animals the cilia appear to perform three very important functions: 1, their vibration causes a vortex in the water, by means of which particles of food in the phytivorous species, and smaller animalcules in the carnivorous tribes, are brought unresisting to the mouth; thus are they the fruitful agents for procuring food; 2, they constitute the sole organs of locomotion; and 3, they are the respiratory organs. In consequence of the general minuteness of animalcules, it is very difficult to discern the precise kind of motion incidental to the vibratile cilia; the superior size, however, of the members of the class *rotifera* has left nothing to be regretted on this account. If the water containing specimens of the common wheel animalcule (*rotifer vulgaris*) be slightly poisoned, sufficiently to interfere with their respiration, the cilia will be seen to move so very slowly that their precise action may be readily perceived. It will then be seen that the down stroke is a very rapid one—so rapid that, in a healthy vigorous state, it cannot be seen, the up strokes being alone visible; and placed on a rounded tubercle, as they are in *R. vulgaris*, their combined action gives the appearance of a wheel revolving, and hence the common name of the class; the up stroke is singularly slow. Striking the arm down quickly, and drawing it back slowly, is the best approximation to the true action of the vibratile cilia.—The excellence of modern microscopes, and the improved methods of conducting the examination of difficult objects, have thrown a new light on this interesting subject. We now know that these remarkable organs are not restricted to the animal kingdom, but are extensively developed in the lower plants, where they appear to perform two of the functions witnessed in the animalcules, viz., locomotion and respiration. They are extensively developed in the common but beautiful fresh-water alga, *volvox globata*, in all the species of *conferva*, *closteria*, &c. In all these locomotive plants, by the application and careful management of the achromatic illuminator, the cilia while the plants are in motion become distinctly visible, but they are no longer to be seen when the plant is at rest.—Passing from the lowest to the higher grades of animal life, even among vertebrates vibratile cilia are constantly found, but differing in their mode of arrangement. In animalcules these delicate hair-like processes appear to be attached directly to the tissues of which they form a part, but in mollusks we find the unmistakable evidence of the development of epithelium as the protecting medium of certain organs. Thus the oyster, mussel (*mytilus edulis*), and all the bivalves, whether of the fresh waters or marine, have their respiratory organs, the gills, covered

with epithelium, and in this particular situation it is always ciliated. So far as is at present known, these organs are constantly to be found in connection with the respiratory function; but in animals as high as the vertebrates, especially the mammalia and man, they are found associated with other functions. The epithelium which coats the base of the frog's tongue is ciliated, and if removed swims freely through a film of water by this agency; in the batrachians, however, it is highly probable that the tongue is an important organ, adjunctive to respiration, and to these organs vibratile cilia belong through all the classes from animalcules up to man. In the warm-blooded mammalia and in man, these organs are found in connection with the epithelium covering the mucous membrane of the trachea, and throughout the distribution of the bronchi; so far they are respiratory. They are also found on the epithelium of the ear, the nose, and of the Fallopian tubes. The most remarkable part of their history remains to be told: they have been seen in active vibration many hours after death in cats, dogs, rabbits, pigeons, &c. In man there has been no diminished action apparent 60 hours after death, and in a tortoise they have been observed in rapid motion three weeks after death, when all the rest of the body was in a putrid condition. It must be quite apparent, therefore, that they possess and maintain motion altogether irrespective of vitality, for they continue to move energetically when all around them is not only dead, but decomposing; and from this latter fact it should appear that their true place is among the vegetative organs of the body. The exact phenomena of their motion are yet to be discovered. (See ANIMALCULES.)

CILICIA, an ancient division of Asia Minor, lying between lat. 36° and 38° N., lon. 32° and 37° E., bounded W. by Pamphylia, N. by Isauria, Lycæonia, and Cappadocia, from which it was divided by the Taurus, E. by Syria, from which it was separated by the Amanus mountains, and S. by the gulf of Issus and the Mediterranean sea. The W. portion, from its mountainous character, was called Tracheia (rough), and the E. portion, composed in great part of plains, Pedia (level). It is a strip of land extending about 300 m. along the shore from W. to E., with a width from N. to S. rarely exceeding 50 and never 70 m., and sloping from the summit of the Taurus mountains toward the sea. The coast of Cilicia Tracheia is abrupt, and a short distance inland there is a mountain ridge. Between this and the Taurus lies the basin of the Calycadnus river (now the Gok Su), which flows E. S. E. to the sea, and with its branches drains a large district. Cilicia Pedia is a fertile and well watered region, producing trees, vines, and such grains as millet, sesame, wheat, and barley. It is crossed by three large streams: the Cydnus (now Tersus Tchai) which rises in the Taurus mountains and flows S.; the Sarus (now Si-

hun), which comes through the gorges of the mountains from Cappadocia; and the Pyramus (now Jihun), which also crosses the northern barrier, and flows S. W. The water of all these streams is very cold, and the current in some parts rapid. The Cydnus was the scene of a cold bath which nearly killed Alexander the Great, and of the first interview between Antony and Cleopatra.—Cilicia is supposed to have been settled by Phœnicians, and the people were distinguished in early times for commercial and maritime enterprise. Though tributary to the Persian empire, the country was in the time of Darius and Xerxes subject to a race of native princes named Syennesis. Cyrus the Younger crossed Cilicia in his expedition against his brother. The Greeks colonized the country in the time of Alexander, after whose death it was made a part of the Syrian empire, and Tarsus afterward became one of the great centres of learning in the East. In the 1st century B. C. pirates swarmed from the coast of Cilicia, and in subduing them through Pompey the Romans acquired the whole country. When Cicero was proconsul the province included also Pamphylia, Pisidia, Isauria, Lycæonia, and the island of Cyprus. Native princes still held out in the mountains until the time of Vespasian. Under Augustus Cilicia was an imperial province, and contained six free cities, Tarsus, Anazarbus or Cæsarea, Corycus, Mopsus, Seleucia, and Ægæ. It now forms the Turkish vilayet of Adana.

CILLY, or **Cilli** (anc. *Celeia*; Slovenish, *Celje*), a town of Austria, in the crown land of Styria, capital of an extensive circle, situated near the junction of the Ködenbach with the San, 36 m. E. N. E. of Laibach; pop. in 1870, 4,203. It is an old town, surrounded by walls and towers, and contains a quaint parish church, having a fine altar and a side chapel with a Gothic throne and ciborium of carved stone. There are ruins of an ancient castle, long the residence of the counts of Cilly, and of the Lazarist convent of St. Joseph, with two towers. Remains of Roman architecture have also been found here. The castle, Neu Cilly, is 4 m. outside of the town. The principal trade is in wine, cereals, cattle, and coal. There are in the vicinity extensive coal fields and deposits of spathic and hæmatite iron ore; an English company was established in 1867 for manufacturing steel and iron.—The site of Cilly has been identified with that of Celeia or Caleia, a city at the S. E. extremity of Noricum, and with the Roman colony of Caleia Claudia, which grew out of the ruins of the more ancient city. During the middle ages it was the capital of the Slavonian district of Zellia. It was ruled by Austrian dukes from 1146 to 1331, and in 1339 it became the capital of the newly created county of Cilly. The assassination of Count Ulric at Belgrade in 1456 putting an end to that line, it has since been Austrian.

CIMABUE, **Giovanni**, called the "father of modern painting," born at Florence in 1240,

died about 1302. He was of noble birth, and while a pupil in the school of the convent of Santa Maria Novella manifested such an aptitude for painting that his parents allowed him to receive instructions, according to Vasari, from some Greek artists who were then restoring the old paintings in the convent chapel. According to others, Giunta Pisano, an artist of considerable merit, was his instructor; and as Guido da Siena is known to have painted as early as 1221, Cimabue's claim to the distinction which tradition and the zeal of his countryman Vasari have conferred upon him is by no means free from doubt. His models, however, were clearly Byzantine, and his earlier works are strongly marked by the characteristics of that school. His great merit consists in his efforts to break away from the formal monotony of his Greek models. The earliest of his works, a St. Cecilia, is still preserved in the church of San Stefano, and a large portion of the frescoes in the celebrated church of St. Francis in Assisi, commenced by Greek painters and continued by Giunta Pisano, are by his hand. Besides these, almost every great European collection contains a specimen of him. In the prime of life he painted his chief work, a colossal madonna and child, for the church of Santa Maria Novella, where it now hangs. The legend states that the Florentine populace testified their wonder and delight at this novel creation of art by carrying it in a triumphal procession to the church. Cimabue's fame thenceforth spread over Italy, and he established a school of painting, in which his ideas received a new development. He evinced a generous appreciation of Giotto, whom tradition says he discovered drawing figures upon the smooth surface of a rock while tending his sheep, and whom he took with him to Florence, and instructed to such purpose that the pupil soon outstripped his master. Cimabue improved little upon the Byzantines in his madonnas, but his patriarchs and apostles have a grand and impressive character. He is described as haughty and disdainful, and exceedingly proud of his lineage, as well as of his acquirements in literature and art.

CIMAROSA, Domenico, an Italian composer, born at Aversa about 1750, died in Venice, Jan. 11, 1801. He studied music under Fenaroli, a pupil of Durante, and soon became so celebrated for his operas composed for the Italian theatres that in 1787 Catharine II. of Russia invited him to become dramatic composer to her court. In 1791 he became director of the Italian opera at Vienna. Here in 1792 he composed *Il matrimonio segreto*, esteemed his greatest opera, which was received throughout Europe with enthusiasm. A peculiarity of it is that brass instruments are excluded from the orchestra, and the other wind instruments are very sparingly used. The accompaniments, nevertheless, are of a rich and brilliant character. The career of Cimarosa in Vienna was cut short by the death of the emperor Leopold

II. in 1792, after which he returned to Naples, where he produced some of his finest works, including *Il matrimonio per susurro*, *La Penelope*, *L'Olimpiade*, *Il sacrificio d'Abrahamo*, *Gli amanti comici*, and *Gli Orazi*. During the French occupation of Naples in 1799, Cimarosa avowed himself so openly in favor of revolutionary doctrines that upon the return of the Bourbons he was thrown into prison, where he languished in close confinement for many months. Released in 1800 on condition that he would quit the Neapolitan territory, he repaired to Venice, where he died the following year, in consequence, it is said, of the treatment to which he had been subjected. During his residence in Venice he brought out his opera *L'Imprudente fortunato*, and had partly composed another called *Artemisia*, at the time of his death. Among his works are 69 operas, 4 oratorios, 3 cantatas, 2 requiems, and a mass, besides much miscellaneous sacred music, and 500 detached pieces composed during his residence at St. Petersburg.

CIMBRI, a warlike people of antiquity, who first appear in the history of the Romans in the year 113 B. C. Together with the Teutons they left their abodes in N. W. Germany with their families, wagons, and cattle, in great numbers, attacked their western neighbors, were repulsed, and, turning their arms southward, crossed the eastern Alps and entered Illyricum, then recently made a Roman province. Their original abode is not known. Some of the later historians suppose them to be Germans, like the Teutons, and inhabitants of the shores of the North sea; so Cæsar, Tacitus, and Pliny, who gave the name of Chersonesus Cimbrica to modern Jutland. Others, like Sallust, suppose them to be Gauls; Greek writers connect their name and history with those of the Scythian Cimmerii of the Crimean peninsula; some modern critics regard them as Celts and relatives of the Cymry of Britain. The consul Papius Carbo first met them in the field near Noreia, in Styria, when the valor of the huge barbarians and their numbers overwhelmed the Romans, and their devastations spread terror all around. They could have easily penetrated into Italy, but choosing to take their course westward, they passed over the Rhine and pillaged Gaul. Another consular army sent thither was also routed in 109; but their offer of alliance and request for lands were rejected by the Romans. Their new allies, the Helvetians, defeated the consul Longinus, who fell in the battle, while his legate was routed by the chief body of the invaders. They next moved in the direction of Italy, crowds of Gauls joining them, and near the Rhône two other consular armies were defeated and their camps taken. The way to Italy was open; terror reigned in Rome. It then happened, for the first time in that city, that no candidate for the consulship appeared. But the Cimbri happily chose another way, passed the Pyrenees, and plundered Spain for a couple of years;

and before they returned the victor of Jugurtha, Marius, who was regarded as the last hope of Rome, and had been three times successively elected consul, formed an army, with which he advanced into Gaul to meet the approaching Teutons, while the other consul, Catulus, opposed the Cimbric, who separately passed the Alps and awaited their allies in the valleys of Italy. In 102, in a battle which lasted several days at Aquæ Sextiæ (Aix in Provence), Marius routed the Teutons, and their allies the Ambrones, with immense slaughter, and hastened to the aid of his less successful colleague in Italy. The terrible Cimbric had passed the Rætian Alps, gliding down, it was said, on their shields, had turned the course of the Adige to pass its valley more easily, and compelled the legions of Catulus to retreat. In 101 Marius fought a battle on the Raudian fields, near Verona. The battle array of the barbarians formed an immense square, covered with their shields, linked together with chains; they were armed with helmets, cuirasses, and spears, and had 15,000 horse; their attack was formidable. But the heat of Italy, the sun and the dust, and the tactics of the Romans, led by Marius, Catulus, and Sulla, overcame them; they were not only defeated, but exterminated: 140,000 men were killed. Still their women fiercely defended their wagons and carts, which formed a kind of fortification. When further resistance became impossible, they killed their children, and then themselves. Some slight remnants of the Cimbric nation reappear afterward, mentioned by Cæsar as inhabiting Belgium, and by Tacitus, who speaks of a Cimbric embassy to Augustus from what is now called Jutland, who in their address to the emperor referred to the wars their ancestors had made on the Romans.

CIMICIFUGA (bugbane; Lat. *cimeæ*, bug, and *fugare*, to drive away), a tall herb of the order *ranunculaceæ*, with incisely toothed leaflets and white flowers. *C. racemosa* (black snakeroot) is found from Maine to Michigan and southward. The root is used medicinally in the substance and in the form of decoction, tincture, and extract. A pint of the decoction may be taken daily, but the tincture and extract should be given in the dose of about half a teaspoonful. In small doses it stimulates the secretion of the mucous membrane, and allays nervous irritability. In large doses it is said to produce vertigo, dimness of vision, and depression of pulse. It has been used with apparent success in chorea, rheumatism, and chronic bronchitis.

CIMMERII, a nomadic race of extreme antiquity, concerning whom there are numerous theories of more or less plausibility, but nothing has been established that seems even to approach to certainty or truth. From the slight descriptions that remain of their habits it may be inferred that they were Tartars. They lived in tents, used wagons, and were "milkers of mares." Modern criticism is nevertheless inclined to connect them with the Celtic race.

(See GOMER.) They appear in a mythical form in the *Odyssey*, as dwellers beyond the ocean-stream, plunged in eternal darkness. The historical Cimmerians seem to have been first known or heard of in Asia Minor and on the shores of the Black sea, where the strait of Yenikale, between the Asiatic mainland and the Tauric Chersonese, or Crimea, was early designated as the Cimmerian Bosphorus. According to Herodotus, they were driven from their abodes in the Crimea by the Scythians, entered Asia Minor by migrating along the shores of the Euxine to the eastward, ravaged it during the reign of Ardys, the successor of Gyges, king of Lydia, and either remained there until the times of Alyattes and Cyaxares (616 B. C.), when they were finally expelled, or were succeeded by a second horde at that period, when both were driven out together.

CIMON, an Athenian general and statesman, born about 510 B. C., died in 449. He was the son of Miltiades, and his mother was Hegesipyle, the daughter of Olorus, a Thracian king. He is said to have married his half sister Elpinice, but as there is no other instance of such a marriage in Athenian history, the truth of this assertion has been doubted. Diodorus says that on the death of his father, in order to obtain the paternal corpse for burial, he took his father's place in prison as guarantee for the payment of a fine of 50 talents inflicted on Miltiades; but other authorities say that the imprisonment was compulsory, as the debt descended to the heir by the Athenian law. According to Cornelius Nepos, he obtained his liberation by the aid of Callias, a man of low birth but of great wealth, who desired to marry Elpinice, and offered to pay the debt of Cimon if the latter would put her away and consent to her nuptials with himself. Cimon at first rejected these proposals, but afterward yielded to the pressing entreaties of his sister. At the battle of Salamis (480) he distinguished himself, and attracted the regard of Aristides, who recognized in the son of Miltiades natural and adventitious advantages which might redound to the future benefit of the conservative party of Athens, and counterbalance the influence of Themistocles. In 477 Cimon and Aristides were placed at the head of the Athenian contingent to the Greek naval armament, under the supreme command of Pausanias, the Spartan regent. They so ingratiated themselves with the confederate Greeks, that on the disgrace of Pausanias the supreme command was transferred to them, and the hegemony of Greece passed thereby from Sparta to Athens. Cimon's first use of his newly acquired power was to destroy the Persian garrison of Eion at the mouth of the Strymon, to capture Amphipolis, and to open that whole country to Athenian colonization. In 476 Cimon expelled the Dolopian pirates from the island of Scyros, and planted an Athenian colony in their place. His next feat of arms was to reduce Carystus, a city of Eubœa, and the

island of Naxos. These victories gave him great influence in Athenian politics, which he threw into the scale of the aristocratic or conservative party, of which Aristides was the head. He contributed to the banishment of Themistocles, the leader of the opposite party. In 466 he won two decisive land and sea battles over the Persians at the mouth of the Eurymedon, on the S. coast of Asia Minor, when 200 Persian ships, out of 350, were captured. Before night-fall he defeated a reinforcement of 80 Phœnician ships. According to Plutarch, these victories were followed by a treaty of peace, concluded by the Persians on the most humiliating conditions; but the historian Callisthenes disputes the statement. Thucydides is silent upon the subject, and some modern historians deny it altogether. These successes and the death of Aristides left Cimon without a rival at Athens. Thasos revolted in 465, and was reduced to obedience by Cimon two years afterward. Two events occurred about this time which brought about the temporary downfall of Cimon. The Athenian colonists on the Strymon and the Chersonese were destroyed by the Macedonians and the Thracians. Cimon was brought to trial for not avenging this injury after the subjection of Thasos; he was accused of having accepted bribes from Alexander, king of Macedon. Pericles was one of the prosecutors, but Cimon was acquitted. While these events were occurring, an insurrection of helots took place at Sparta. Cimon, who admired the Spartans, persuaded the Athenians to send an army to the aid of their rivals. The Spartans insultingly dismissed the aid so generously offered, and the resentment of the Athenians naturally recoiled upon Cimon, who stood responsible for the original movement. His ruin was completed by his opposition to the democratic party on the question of curtailing the power and jurisdiction of the areopagus. Upon the victory of the popular party, under the lead of Pericles and Ephialtes, Cimon was ostracized about 459. In 457 a Lacedæmonian army, posted at Tanagra, threatened Attica. It professed friendly feelings toward the aristocratic party of Athens, and hostility only to the then dominant democracy. Cimon, though an exile, begged to be allowed to fight in his tribe in defence of his country; the Athenians, suspicious of treachery, refused permission. Cimon then besought his friends and retainers, as they valued his character, to do their duty. These friends carried his panoply to the field of Tanagra, and fell around it to the last man; the Athenians were utterly defeated. About 454, after five years of exile, he was recalled at the instance of his great antagonist, Pericles. He was employed in effecting the five years' truce with Sparta, in 450. The next year he was intrusted with an expedition of 200 ships to avenge on the Persian empire the disasters the Athenians had lately suffered in Egypt. While besieging Citium, a town on the S. coast of

Cyprus, he fell a victim either to disease or a wound. His lieutenants, while carrying his remains back to Athens, fell in with and defeated a fleet of Cilician and Phœnician galleys, and at the same time beat the Cyprians on land. Cimon was buried in Athens, and his tomb was visible there in the time of Plutarch (A. D. 100). In his private life Cimon is spoken of by the ancients as the type of generosity, frankness, and affability. After the recovery of his patrimony, he kept a free table for all citizens of his district. He distributed alms in public with prodigality. At his own expense he laid the foundation of the long walls which joined the Piræus to the city. He beautified his private grounds, and threw them open to the public, who were allowed to pluck the fruit and flowers. He bequeathed to the Athenians a pleasure ground in the Ceramicus, which afterward became the seat of the famous academy of Plato.

CINALOA. See **SINALOA.**

CINCHONA, Peruvian or Jesuits' bark, named in honor of the countess of Chinchon, the wife of the viceroy of Peru, who, having been herself cured thereby, is said to have first carried the bark to Europe, where she used it successfully in the cure of intermittent fever about 1640. Soon after its introduction into Spain, the Jesuits began to receive it from their brethren in Peru, and through them it was spread over Europe, in consequence of which it was called Jesuits' bark. It is the dried bark of many species of the genus *cinchona*, a tree belonging to the order *rubiacæ* and suborder *cinchonaceæ*. Until very recently it has been impossible to determine with accuracy from which species of cinchona the different varieties of bark were obtained, but late investigations with the aid of chemistry have thrown much light upon this subject, though something yet remains to be learned. Although each species or even variety of cinchona may be supposed to produce a separate kind of bark, and although these varieties run into each other in such a way that hardly any two botanists agree as to the proper lines of separation, yet the commercial products may be divided into three classes, yellow, red, and gray barks. To these may be added the non-official or Carthagena barks, brought from the northern Atlantic ports of South America. The three varieties first mentioned are obtained from Pacific and South Atlantic ports. The source of the yellow bark is said by the "United States Dispensatory" to be *C. calisaya*, one of the largest and finest species, growing in Peru and Bolivia. A variety of this species, *C. Josephiana*, is but little more than a shrub. The bark of *C. Boliviana*, and the better pieces of *C. ovata*, *C. scrobiculata*, and *C. micrantha*, are probably often mixed with the parcels of calisaya bark. The first mentioned species is by some botanists regarded as a variety of *C. calisaya*. The red bark is derived from *C. succirubra*, a large tree, growing upon the western slopes of Chim-

borazo and the neighborhood. *C. nitida* is also indicated by Weddell as a source of this variety. The pale or gray barks are referred to *C. Condaminea* and *C. micrantha* by the "United States Dispensatory," but other species (*C. ovata*, *scrobiculata*, *macrocalyx*, and *writusina*) probably contribute to the supply. The Carthagena barks are probably derived partly from some of the same species with the kinds just mentioned, and partly from *C. cordifolia*, *C. lancifolia*, and *C. Pitayensis*. Some of them are of very good quality, and are extensively used for the extraction of the alkaloids. The "false" barks are derived from inferior species of cinchona and allied genera.—The cinchonas appear to thrive best in regions subject neither to extreme heat nor extreme cold, where a somewhat even temperature prevails throughout the year, and where they are partially protected by their neighbors from the direct rays of the sun. These conditions are fulfilled upon the slopes of the Andes between

Cinchona calisaya.

lat. 19° S. and 10° N. For more than a century after Peruvian bark came into use, it was supposed to exist only in Loxa in the ancient kingdom of Quito, and in a few neighboring localities; but in the year 1753 it was discovered in various other places of a corresponding elevation with Loxa above the sea. Little advantage, however, resulted from this; but some 20 years later, under the patronage of the Spanish government, researches were made in New Granada, which resulted in the discovery of several species of cinchona. At a subsequent period supplies of the bark were obtained from other sources, which are now shipped from many of the South American ports, including some ports in the Caribbean sea. Considerable care and experience are necessary in collecting the barks, to select those most valuable, and to know the proper age at which a branch should be decorticated. The bark is collected between May and November. The tree is usually cut down and

then stripped, which is the most economical plan, as fresh shoots spring up from the old roots. But the Indians, to save themselves the trouble, often strip the bark entirely from the tree while it is standing, thus destroying it altogether. Owing to the reckless manner in which the bark has been collected, and the entire absence of any efficient protection to the forests on the part of the government or provision for the cultivation of the trees in plantations, the danger of a serious diminution in the supply of this valuable drug is by no means a remote one. For many years all the large trees of valuable species have disappeared from easily accessible regions. Dr. Weddell in 1847, in order to see the *C. calisaya* in its full vigor, was obliged to make long journeys on foot through the forests, and endure the hardships and privations of the poor *cascañeros* or bark collectors. The Dutch and British governments have made successful attempts to introduce the cinchona into their East India possessions, in Java, and various parts of Hindostan, where the mountainous regions furnish the necessary temperature and moisture for their growth. It has been found that the yield of some species of cinchona in alkaloids may be much increased by covering the bark with moss, and also that a longitudinal strip of bark may each year be taken from a tree without destroying it; the decorticated portion renewing, if "mossed," its former covering, at least as rich in alkaloids as before. Bark from the English plantations has already been introduced into commerce. More or less successful attempts at cinchona culture have been made in Jamaica, the isle of Réunion, Guadeloupe, Brazil, the Azores, and Algeria. It is possible that situations may be found within the limits of the United States suitable for the culture of the cinchonas. The division of the bark into flat and quilled is determined simply by the part of the tree from which it is taken, whether trunk or branches, and the method of drying it, whether under pressure or allowed to roll up.—The medicinal value of Peruvian bark depends upon the alkaloids which it contains. These are quinia, cinchonina, quinidia, cinchonidia, quinicina, and cinchonin. Another alkaloid called cinchine is found in small quantity in some of the inferior varieties. It is probable that the three latter alkaloids are artificial derivatives from the former. In addition to these, the bark contains in varying proportions gum, starch, lignine oil, yellow coloring matter, insoluble red coloring matter, soluble red coloring matter or cincho tannic acid, kinic and kinovic acids. The various alkaloids are produced in the bark itself, and that probably by a reaction between the ammonia, which (according to De Vry) is everywhere contained in the plant, and the cincho-tannic acid. The general condition of the alkaloids is that of being more pure and easily separated from adventitious substances in the bark of the branches, somewhat less so in that of the

trunk, and of all most impure in that of the roots. Quinia, the most important of the alkaloids, has the formula $C_{10}H_{14}N_2O_4$, is crystallizable, slightly soluble in hot and cold water, and very soluble in alcohol, ether, and chloroform. It forms crystallizable salts with several acids. It may be precipitated as a hydrate from a solution of a salt by an alkali or alkaline earth. Ammonia in excess redissolves the precipitate. Sulphate of quinia, or more properly the disulphate, is the medicine commonly known as quinine. It consists of one equivalent of sulphuric acid, 40, two of quinine, 324, and 8 of water, $72=436$. It is in fine, white, silky crystals, which on exposure to the air effloresce and lose their form together with their water of crystallization. It dissolves in 30 parts of boiling water, but separates on cooling. In ether it is slightly soluble. Alcohol when cold takes up one part in 60, and the diluted acids, tartaric and oxalic, dissolve it freely. In water acidulated with sulphuric or other acid it readily dissolves, and this property is taken advantage of in administering the medicine in a liquid form. The manufacture of quinine is extensively carried on in Paris, in Stratford, England, and in Frankfort, from which place Russia, Prussia, and Austria are chiefly supplied with this medicine. In Philadelphia the business of extracting it from the bark is conducted in chemical establishments also upon a very large scale. The quinine in the process of its extraction is commonly converted into the sulphate, which is the salt chiefly employed in medicine, and of which from 2.5 to 3 per cent. is usually obtained from the yellow bark. The processes employed vary somewhat in different countries. From a strong decoction of the bark in water, acidulated with hydrochloric acid and filtered, the quinine may be set free from its combination with kinic acid and precipitated by addition of lime water; some lime combined with coloring matter falls with it. The precipitates are well washed with water, and the residuum is pressed, dried, and pulverized. It is then repeatedly treated with alcohol, which dissolves the quinine and leaves most of the impurities. These being separated, the solution is concentrated by evaporation to a brown viscid mass, which is impure quinia; or the tincture in the distilling vessel may be neutralized with sulphuric acid, and the alcohol being then distilled off, an impure sulphate is obtained which crystallizes on cooling. This is expressed, and then dissolved in boiling water to which purified animal charcoal has been added. It is filtered while hot, and then allowed to cool and crystallize. The purification is completed by again dissolving and crystallizing. Sulphate of cinchonia is commonly present, but being more soluble does not crystallize so readily as the sulphate of quinia, and remains in the mother liquor. This also contains what Liebig regards as an amorphous variety of quinine, which is analogous in its properties to uncrystallizable sugar; it is known as qui-

noidine, and possesses the same medical properties as the sulphate. It probably consists chiefly of quinic acid and cinchoninic acid. The soluble salts of quinia form precipitates with tannic acid, with the soluble salts of lead and baryta, with a solution of iodine in iodide of potassium, and with the iodohydrargyrate of potassa. It is distinguished from the other alkaloids, with the exception of quindia, by the production of an emerald green color when the solution is treated first with the solution of chlorine and then with ammonia, and which changes to a white or violet upon saturation with a dilute acid. Some of the salts of quinia, especially the sulphate, possess the remarkable property, called fluorescence, of rendering visible as a pale blue the ultra-violet rays of the spectrum, and an exceedingly small quantity may be detected by examining even in ordinary light a long tube filled with its colorless solution. The test is much more delicate when the electric light is used. Hydrochloric acid or chloride of sodium renders the reaction much less distinct, or in ordinary light imperceptible. The sulphate of iodoquinia, as well as the corresponding salts of the other alkaloids, possesses the property of polarizing light, in which it is equal if not superior to tourmaline. Quindia is isomeric with quinia, and resembles it in many of its chemical reactions. It is distinguished from quinia by its greater facility of crystallization, its less solubility in ether, and its influence on polarized light. It forms a precipitate with iodide of potassium, a property possessed by no other cinchona alkaloid. Cinchonia has the formula $C_{10}H_{14}N_2O_2$, is crystallizable, only very slightly soluble in water, cold alcohol, and ether. It forms salts with acids. It is obtained chiefly from the pale barks. Cinchonidia is isomeric with cinchonia, but differs from it in being more soluble in ether and also in its influence on polarized light. Commercial quindia generally consists of quindia proper with a much larger proportion of cinchonidia. Quinic acid and cinchoninic acid are isomeric with quinia and cinchonia respectively, but are uncrystallizable. The different varieties of bark contain these alkaloids in varying proportions, the yellow yielding chiefly quinia, the pale a larger proportion of cinchonia with but little quinia, and the red a considerable proportion of each. According to the "United States Pharmacopœia," cinchona bark should contain at least 2 per cent. of the proper cinchona alkaloids which yield crystallizable salts.—The cinchona alkaloids, and especially the sulphate or disulphate of quinia, are largely used in medicine. Their most striking and earliest discovered property is that of preventing an expected access of intermittent fever. For this purpose quinia should be administered in large doses. Two to 15 grains may be given at a time some hours before the expected chill, but not more than 30 or 40 grains should be given during the 12 hours preceding one. If administered sub-

cutaneously, a smaller quantity will suffice. It is also extensively used in other forms of malaria and diseases dependent thereon. For these uses, and also as a prophylactic (against malaria), quinia has been found almost as important to the traveller in malarial regions as a good supply of food. It has been said that the British rule in India is founded upon cinchona bark. A full dose of quinia reduces the pulse and the bodily temperature, and it has been applied in diseases not malarial, such as typhoid fever, erysipelas, pyemia, and rheumatism. It has until recently been difficult to explain the acknowledged therapeutic action of quinia by any well ascertained physiological action; but within a few years it has been discovered to possess certain properties which may serve as a clue to the method of its action in disease. It has been found that it is capable of arresting or delaying various kinds of fermentation, of killing the microscopic organisms accompanying putrefaction, of arresting the amoeboid movements of the white blood corpuscles, and of preventing the escape of these corpuscles from the mesenteric vessels of the frog, when prepared as in the well known experiment of Cohenheim. In animals poisoned by the injection of putrid fluids into the veins, it has been found that those to which quinia was administered lived longer than those without it. The other alkaloids probably have the same power, but in a less degree. Cinchonia is about one half less powerful than quinia. The amorphous residue left after the crystallization of quinia may be used for the same purposes, but is inconvenient from the circumstance of there being no satisfactory test for its strength and purity. Quinia and the other alkaloids give rise to certain nervous symptoms, of which the most prominent are headache, a feeling of fullness and tightness in the head, buzzing in the ears, and temporary deafness. Permanent deafness is a rare accident. Quinia or the other alkaloids may be administered in the form of pills or in solution. In the latter form the intense bitterness is a serious objection to their use. This may be partially disguised by sirups, aromatics, extracts of licorice, dandelion, &c. Tannin renders quinia less bitter because less soluble. Various combinations of quinia with iron, strychnia, phosphorus, &c., are in use. When a simple tonic effect is desired, the preparations of the bark itself may be advantageously used.

CINCINNATI, the chief city of Ohio, capital of Hamilton county, and in population the eighth city of the United States. It is situated in lat. $39^{\circ} 6' N.$, lon. $84^{\circ} 27' W.$, on the N. bank of the Ohio, 250 m. direct, or by the river 466 m., S. W. of its head at Pittsburgh, Penn.; 290 m. direct, or 500 m. by river, N. E. of its mouth at Cairo, Ill.; and 390 m. W. of Washington. Its site is peculiarly favorable to commerce, comfort, and health. The main city lies on a plateau, through which the Ohio passes from N. E. to S. W. This plain is nearly 12 m. in cir-

cumference, and is divided by the river into nearly equal parts. The city is surrounded by hills from 400 to 465 ft. in height, forming one of the most beautiful natural amphitheatres on the continent, from whose hilltops may be seen the splendid panorama of the cities below, and the winding Ohio. No other large city of the United States affords such a variety of position and scenery. Commencing on the east, the hills border the river within 500 yards of its bank for $4\frac{1}{2}$ m.; then recede, form an amphitheatre around the plateau on which the city was first laid out, and return with a bold promontory to the river 3 m. below; thence they follow its windings, within 300 yards of the shore, $1\frac{3}{4}$ m. further, to the western corporation line. By following ravines between the spurs, practicable roads have been constructed to the summits of these hills. The greater part of the city is built upon two terraces or plateaux, respectively 60 and 112 ft. above the river. The amphitheatre of hills enclosing these plateaux is cut by the ravine-like valley of Deer creek entering from the northeast, and by the broad plain of Mill creek valley, extending from the north through the W. extremity of the plateau portion of the city to the river. The former is a dry torrent bed; the latter a considerable stream, with low banks and a valley within the city from 1 to $1\frac{1}{2}$ m. wide. Through this valley the city has its greatest breadth, $5\frac{1}{2}$ m. The upper plateau, uniting with the higher grounds of Mill creek valley, extends many miles north with very little increase of elevation, thus affording space for future growth. The city stretches along the river about 10 m., from and including the village of Columbia on the east to that of Riverside on the southwest, with an average width of 3 m., and embracing an area of 24 sq. m. The main body of the city, including the business portion and the densest population, borders on the river between the mouth of Deer creek on the east and that of Mill creek on the west, a distance of $2\frac{1}{2}$ m. North of East Liberty street and Hamilton road, the hillsides from Deer creek to Mill creek are terraced with streets, and generally covered with dwellings to their summits. Mount Adams, overlooking the S. E. corner of the plateau, has streets thickly lined with dwellings on its summit and W. and S. sides. The remainder of the city, including the narrow valleys along the river, above and below the city proper, the village of Cumminsville next the northern corporation line in Mill creek valley, and the several tableland villages, from Woodburn on the east to Fairmount on the west, is irregularly built. In the N. W. part are native forests and cultivated farms. On the western hills are vineyards and gardens. Between Harrison avenue and the 25th ward (Cumminsville) are many vegetable gardens. The numerous villages annexed to the city since 1868 retain their former names. The most important of these,

enumerating from east to west, are Columbia, Walnut Hills, Mount Auburn, and Cummins-ville. The river at this point rises during floods from 50 to 55 ft. above low-water mark. In 1832 it rose to a height of 62½ ft., and 57 ft. in 1848. Nearly 1,200 acres of city land, chiefly in Mill creek valley, are subject to inundation by extreme high water; but many acres have been filled above high-water mark and built upon, and further improvement is in rapid progress. Cincinnati is noted for its picturesque surroundings and suburbs. On the opposite bank of the Ohio, on a plateau surrounded by an amphitheatre of hills, are Covington and Newport, Ky., separated by Licking river. The outer highland belt of the city commands distant views of hills in Kentucky and Ohio, and of the valleys of Mill creek, the Licking, and the Ohio. It is beautified by elegant residences in the midst of extensive high-

ly cultivated landscape lawns, whose shrubbery is often the native forest, and is traversed by winding avenues. From the eastern corporation line, through East Walnut Hills and Woodburn to West Walnut Hills, mansions occupy grounds of from 3 to 75 acres. Blue limestone is used in the construction of the finest buildings. West Walnut Hills and Mount Auburn, though in parts quite compactly built, abound in elegant and costly residences, each having from one to five acres of grounds. The highlands W. of the city, between Fairmount and the river, have beautiful scenery, but owing to difficulty of access they are but partially occupied. Outside the city, 3 m. from the post office, and overlooking Mill creek valley to the west, is the village of Clifton, comprising many beautiful groves and costly residences. Fences and hedges are almost entirely discarded, and the luxuriant

Cincinnati.

lawns extend to the roadside, covered with every variety of trees. Here the finest mansions are of blue limestone. The grounds around them range from 10 to 80 acres in extent. There are here fine specimens of the Anglo-Norman, Gothic, and modern Italian styles of architecture. Avondale lies E. of Clifton and N. of Mount Auburn and Walnut Hills, 3 m. N. E. of the custom house, and contains 800 acres. It has elegant residences with large grounds, and commands views of the surrounding hills; but it is shut out from river prospects. College Hill, the seat of Farmer's college and the Ohio female college, is situated W. of and overlooking Mill creek valley, 7 m. N. of the custom house, on the highest ground in Hamilton county. Cincinnati proper is rapidly surrendering its dwellings to business, while residences

multiply on the hills and in the suburbs. —The increase of the population of Cincinnati has been very rapid. In 1800 it was 750; in 1810, 2,540; 1820, 9,602; 1830, 24,831; 1840, 46,338; 1850, 115,436; 1860, 161,044; 1870, 216,239. Of the population in 1870, 136,627 were of native and 79,612 of foreign birth; 210,335 white, and 5,900 colored. The foreign population embraced 49,448 born in Germany, 18,624 in Ireland, 3,526 in England, 2,093 in France, 995 in Switzerland, 787 in Scotland, and 507 in Wales. There were 53,814 voters. The city contained 24,550 dwellings, with an average of 8.81 persons to each; and 42,937 families, with an average of 5.04 in each. The number of persons engaged in industrial occupations was 77,923, of whom 1,420 were employed in agriculture, 25,666 in professional and personal services, 16,865 in trade and

transportation, and 33,972 in manufactures and mining.—The city is regularly laid out, the streets crossing each other at right angles. They are generally from $1\frac{1}{4}$ to $2\frac{1}{4}$ m. long, with a width varying from 50 to 100 ft. West of Central avenue they run N. from the river and E. from Mill creek, while E. of that avenue their direction from the river is slightly W. of N. The streets and avenues are generally paved or macadamized, many of them being adorned with shade trees. The buildings are substantial, and chiefly of brick. A grayish buff freestone for fronts is almost universally used for large business houses and the finest residences in the city proper, though many of the residences on the hills are of wood. The prevailing height of business buildings is five stories, though many are six. Dwellings are generally high and narrow, and seldom have front yards. The chief mercantile quarter covers about 300 acres, and lies between Fifth street and the river, and Broadway and Smith street. Business is not concentrated as in most other cities. Manufactories are scattered through all parts of the city and its suburbs. Pearl street, which contains nearly all the wholesale boot and shoe and dry goods houses, is noted for its splendid row of lofty uniform stone fronts between Vine and Race streets. Fourth street, the fashionable promenade, and the most select retail business street, between Broadway and Central avenue, a mile in extent, is noted for its splendid stone front buildings. Third street, between Main and Vine, contains the banking, brokerage, and insurance establishments, and the attorneys' offices, and W. of Vine street the large clothing houses. Within a quarter of a mile of the custom house and post office are the chief theatres, newspaper offices, and libraries. In Pike street, in Fourth street from Pike to Broadway, and in Broadway between Third and Fifth streets, are the mansions of the "east end;" in Fourth street W. of Smith street, in Dayton street, and in Court street between Freeman and Baymiller streets, those of the "west end." The large district N. of the Miami canal, which enters the city from the N. W. and extends S. to Canal street, thence E. to the Ohio river, is known as "Over the Rhine." It is densely populated, almost exclusively by Germans, has numerous beer gardens, saloons, and concert halls, and is thoroughly German in its characteristics. In this vicinity are all the great breweries of Cincinnati. At the foot of Main, Sycamore, and Broadway, along Front street, is the public landing, an open area paved with bowlders, 1,000 ft. long, with a mean width of 425 ft. Above the public landing, for $1\frac{1}{2}$ m., are the marine, railway, and dry docks, and boat yards. Between Central avenue and the foot of Fifth street are situated the extensive coal wharves and elevators. In the vicinity of the city there are many beautiful drives; one of the most attractive is that from the Brighton house, at the junction of Central avenue and Freeman

street, to Spring Grove cemetery, and thence returning to the city by way of Clifton or Avondale.—Cincinnati is well provided with parks and public grounds. Chief among these is Eden park, on a hill in the eastern district, and commanding magnificent views of the city, the valley of the Ohio, and the surrounding country. It contains 216 acres. Lincoln, Washington, Hopkins, and the city parks are in central parts of the city, and contain an aggregate of about 25 acres. Burnet Woods, on the hill N. of the city, purchased in 1872, contains 170 acres, nearly all forest. Spring Grove, one of the most beautiful cemeteries in the west, lies 3 m. N. W. of the city, in the valley of Mill creek, and is approached by an attractive avenue 100 ft. wide. It contains 600 acres, comprising much picturesque wooded land tastefully laid out, and has about 100

Tyler Davidson Fountain.

monuments, costing from \$5,000 to \$15,000 each. The entrance buildings are in the Norman Gothic style, and cost more than \$50,000. The chief attractions are the Dexter mausoleum, representing a Gothic chapel, and the soldiers' monument, cast in Munich, and erected in 1864. It is a bronze statue, with granite pedestal, representing a soldier of the United States standing on guard. The most notable work of art in Cincinnati is the Tyler Davidson fountain, in Fifth street (140 ft. wide), between Vine and Walnut. It stands on a freestone esplanade 60 ft. wide by 400 ft. long. In the centre of a porphyry-rimmed basin 40 ft. in diameter is the quatrefoil Saxon porphyry base supporting the bronze work, whose base is 12 ft. square and 6 ft. high, with infant figures in niches at each corner representing the delights of children in water. Its faces are ornamented

with panels containing figures in low relief representing the various uses of water to mankind. From the upper part of the bronze base extend four great basins, one to each side, with perforated rims; two of the basins have jets. From the top of the base or socle rises a column up whose sides vines ascend and branch at the top in palm-like foliage. Around this column are groups of statuary; and on its summit stands a gigantic female figure with outstretched arms, the water raining down in fine spray from her fingers. Four bronze figures on pedestals around the rim of the basin serve as drinking fountains. There are in all 15 figures. The height of the topmost figure above the street is 45 ft. The work was cast in Munich at the royal bronze foundery, and cost nearly \$200,000. It was suggested by Mr. Tyler Davidson, and after his death completed and presented to the city by Mr. Henry Probasco. It was unveiled Oct. 6, 1871. It plays during warm days from morning till midnight. The suspension bridge from Cincinnati to Covington, designed by John A. Roebling, and constructed at a cost of \$1,800,000, extends 1,057 ft. between the towers, from centre to centre, and with the approaches is 2,252 ft. long. Two wire cables, each a foot in diameter, pass over stone towers 200 ft. high, each surmounted by two turrets of 30 ft., and sustain the bridge, all iron except the flooring, at a height of 103 ft. above low-water mark. It has a double wagon way between the cables, passing through an arched opening in each tower, and a foot way on the outer side of each cable. It was opened for use Jan. 1, 1867. About 3,000 ft. further up the river, a wrought-iron railroad pier bridge, 100 ft. above low water, with wagon and foot ways on its sides, crosses the Ohio from Cincinnati to Newport. It has 11 spans, the widest being 405 ft. The distance between the abutments is 1,780 ft. The railway track, with its approaches, is 3,090 ft. long, and the highway track 2,082 ft.—Cincinnati contains many public edifices distinguished for their size and architectural beauty. The United States government building, 150 ft. on Vine street by 80 ft. on Fourth street, is of sawed freestone, three stories high, in the Roman Corinthian style; in Fourth street it has a porch supported by six columns of freestone. It contains the post office, depository, custom house, United States court, and other government offices. The county court house, in Main street, facing Court street, is 175 ft. square and three stories high, nearly fire-proof, of iron, brick, and Dayton stone, in the Roman Corinthian style. The front in Main street has a porch with six Corinthian columns of stone. It contains all the courts, except the police and national, all the county offices, and the law library. It was built in 1853, at a cost of \$500,000. With the county jail, 150 ft. square, in its rear, it occupies an entire square. The city buildings, erected in 1853, are of brick, 205 ft. long by 52 ft. wide. The ground, in-

cluding the city park of $1\frac{1}{2}$ acre, cost \$60,000; the buildings about \$27,000. They contain the council chamber, police court, and all the city offices. The city workhouse, completed in 1868, is in Mill creek valley, $3\frac{1}{2}$ m. from the custom house. It is of brick, in Romanesque style, 515 by 55 ft.; cost of buildings, \$600,000; the grounds, 26 acres, cost \$50,000. It has cells for 700 prisoners. In its rear are workshops and grounds, enclosed by a high stone wall. Longview asylum for the insane, at Carthage, 10 m. from the city, is of brick, in the Italian style, 612 ft. long and three and four stories high. Its value, with 110 acres of grounds, is \$1,000,000. Cincinnati hospital, in Twelfth street, between Central avenue and Plum street, occupies a square of about four acres. It consists of eight distinct buildings, arranged around a central court and connected by corridors. In the centre, fronting Twelfth street, is the administrative block, four stories high; opposite it, in the rear, are the culinary and laundry buildings; flanking these are six pavilions, three on a side, arranged *en echelon* and three stories high, built of brick trimmed with freestone, in the modern French style, with Mansard roofs. The hospital was first occupied in January, 1869, and cost, with furnishing, \$703,572, exclusive of the ground, which is worth \$300,000. It has capacity for 700 patients. The public library building, between Sixth and Seventh streets, occupies a lot 80 ft. wide in Vine street, running back 190 ft. to College street. It comprises two distinct buildings, connected by a corridor two stories high, 33 ft. long by 44 ft. wide. The building fronting on Vine street is 80 by 45 ft., and four stories high; the one in the rear is 80 by 112 ft. An iron arch, 40 ft. wide and 90 ft. long, rests on the brick walls of the clear roof. These walls are supported by 16 wrought-iron columns, from which to the wall, 18 ft. above the ground floor, is the gallery. The buildings are of brick, in the Romanesque style, with a stone front in Vine street. The main hall will cost \$500,000; the entire buildings, with the grounds, about \$675,000. They are built from funds raised by taxation by the board of education. Masonic temple, on the N. E. corner of Third and Walnut streets, an imposing freestone front building in the Byzantine style, is 195 by 100 ft., four stories high, with two towers each 140 ft., and a spire 180 ft. high. The basement, ground, and second stories are used for offices and business purposes; the two upper stories for lodges, &c. It was commenced in 1859, and completed at a cost of about \$200,000. Pike's opera house, in Fourth street, between Vine and Walnut, is one of the most imposing structures of the kind in the United States. It is five stories high, with a front of 134 and a depth of 170 ft. The front is of fine sandstone, in the Elizabethan style. Mozart hall, corner of Vine and Longworth streets, is a massive stone building, with an auditorium which will seat 3,000 persons. St.

Xavier's college, a splendid building in the Romanesque style, on the corner of Seventh and Sycamore streets, is 70 by 125 ft., and four stories high. When extended it will be L-shaped. It is of brick, with profuse ornaments of stone, and a splendid double portico of the same material. It cost \$125,000. The Wesleyan female college, in Wesley avenue, between Court and Clark streets, erected in 1868, is built of white stone, in a highly attractive style of architecture, and is surrounded by ornamental grounds. It is 180 ft. long, 60 and 90 ft. deep, and four stories above the basement, with a Mansard roof. It has accommodations for 300 day and boarding pupils. The Hughes high school, in Fifth street, is an imposing edifice in the Gothic style, with octagon towers at the corners. The medical college of Ohio is a quaint-looking structure in Sixth street, W. of Vine. The finest church edifice in Cincinnati is St. Peter's (Roman Catholic) cathedral in Plum street. It is of Dayton limestone, in pure Grecian style, 200 ft. long and 80 ft. wide, with a stone spire 224 ft. high. Fronting Plum street it has a portico supported by ten sandstone columns, arranged by fours on three sides, which are approached by flights of full-length steps. The height of the interior, from floor to ceiling, is 55 ft.; 18 stone pillars, 9 on each side, separate the nave from the aisles. The altar, of Carrara marble, was made in Genoa. St. Paul's church (Methodist), in Seventh street, in the English transition style of the 13th century, is of blue limestone, cruciform, 130 by 85 ft. It has a finely finished interior, and a spire 200 ft. high. It cost (in 1871) \$175,000. St. John's (Episcopal) church, in Seventh and Plum streets, built in the Norman style, is of stone and stuccoed brick. It is cruciform, 90 by 105 ft. in extreme dimensions. Its most striking features are its unfinished square towers, rough ashlar gable, and deep and lofty Norman door, facing Seventh street. The first Presbyterian church, in Fourth street, is noted for its huge tower, surmounted by a spire 270 ft. high, terminating with a gilded hand, the finger pointing upward. The two Hebrew temples are fine and large structures. That in Plum street is of brick, profusely ornamented with stone, built in the Moorish style, 120 by 110 ft., and cost \$250,000. That in Mound street is also of brick trimmed with stone, Gothic in style, 135 by 60 ft., and gorgeously frescoed inside.—North of the Ohio, Cincinnati has only three natural avenues of approach by railroad: two between the base of the hills and the river E. and W. of the city, and one through Mill creek valley from the north. In 1873 these approaches were occupied by six railroads, three of which had double tracks for a distance of 15 to 25 m. from the city. These lines were used by the following companies: Atlantic and Great Western; Cincinnati, Hamilton, and Dayton; Cincinnati and Indiana; Cincinnati and Indianapolis Junction; Cincinnati, Rich-

mond, and Chicago; Cincinnati, Sandusky, and Cleveland; Cincinnati and Muskingum Valley; Cleveland, Columbus, Cincinnati, and Indianapolis; Dayton and Michigan; Harrison Branch; Little Miami; Marietta and Cincinnati; and Ohio and Mississippi. Terminating at Covington are the Kentucky Central, and the Louisville, Cincinnati, and Lexington railroads. The daily arrivals and departures on these roads are 124 passenger and 150 freight trains. These railroads enter four depots, all near the river, one in the eastern, one in the central, and two in the western part of the city proper. The eastern and western depots are connected by a track through the city for restricted use in the transfer of freight. The Miami canal connects with Toledo on Lake Erie. Telegraphic communication is afforded by the Western Union company, with 40 lines, the Pacific and Atlantic with six, and the Atlantic and Pacific with two. There are eight lines of river packets running regularly between Cincinnati and various points on the Ohio, Cumberland, Mississippi, Arkansas, White, and Red rivers. There are 14 lines of omnibuses and stages running from the city to distances of from 5 to 80 m. into the country; and 14 lines of street railroad, with 45 m. of track, traversing the city in various directions. An inclined railway for passengers by a plane about 800 ft. in length, operated by steam, makes an ascent of 275 ft. from the bottom to the top of one of the northern hills. Three other incline railways, to ascend the hills at other points, are projected. Besides the two bridges above mentioned, there is communication by 3 ferries with Kentucky.—The central position of Cincinnati in relation to extensive producing regions and to leading channels of commerce, by water and by rail, renders it one of the most important commercial centres of the west. The commercial growth of the city is exhibited in the following statement of the aggregate imports and exports for the years ending respectively Aug. 31:

YEARS.	Imports.	Exports.
1854-'55.....	\$67,501,341	\$38,777,394
1858-'59.....	94,213,247	66,007,707
1862-'63.....	144,189,213	102,397,171
1866-'67.....	333,961,233	192,929,317
1868-'69.....	283,927,293	163,054,358

The number and tonnage of steamers and barges plying between Cincinnati and other points, during the years specified, are as follows:

	No.	Tonnage.		No.	Tonnage.
1850.....	233	49,274	1870.....	327	78,109
1860.....	333	71,642	1871.....	325	81,801
1865.....	446	91,636	1872.....	354	83,721

The value of the chief articles represented in this trade, for the two years ending Aug. 31, was:

ARTICLES.	1870-'71.		1871-'72.	
	Imports.	Exports.	Imports.	Exports.
Ale, beer, porter	\$56,705	\$1,296,999	\$46,100	\$1,439,075
Boots and shoes	8,602,374	3,995,122	8,690,168	3,442,672
Butter	1,711,775	22,576	1,673,952	83,138

Whiskey	16,592,816	18,750,450	18,962,460	19,788,200

About three fourths of the transportation of exports from Cincinnati is by railroads and canals, one twelfth by river up the Ohio, and one sixth by river down the Ohio and Mississippi and on their tributaries. Boats in 1873 averaged 330 tons capacity, against 250 tons in 1855. Vessels carrying 1,500 tons run to this port. The employment of tow boats, with barges for carrying all classes of merchandise, is extensive and daily increasing. Such a boat of 350 tons capacity will take 1,200 tons of freight in barges up stream, or 3,000 tons down. The completion of the canal around the falls of the Ohio, at Louisville, enabling boats 300 ft. long and 80 ft. wide to pass through nearly the whole year, has had an important effect upon the river trade of Cincinnati. Since the opening of this great work in 1872, large Mississippi river steamers have been enabled to come up to the city. Boat-building constitutes an important industry. In 1872, 20 steamboats and barges of 7,761 tons

were built, and in 1871, 25 of 12,758 tons. By the act of congress, July 14, 1870, Cincinnati was made a port of entry. Direct foreign importations since then have been, in import value, as follows: 1870, \$1,058,226; 1871, \$1,326,868; 1872, \$1,463,984. The chief articles of import are tea, coffee, and textile fabrics. In 1871 Cincinnati merchants withdrew from the original port of entry \$52,000,000 worth of imported goods.—The central situation of the city with reference to extensive iron and coal producing regions has given it great advantages as a manufacturing centre. The following is a summary of the manufactures of Cincinnati in 1872 (to Dec. 31), compared with 1860:

CLASSIFICATION.	HANDS.		VALUE OF PRODUCTS.	
	1860.	1872.	1860.	1872.
Iron	8,535	10,237	\$5,305,606	\$25,725,431
Other metals	770	1,573	1,464,738	4,344,650
Wood	4,842	8,234	5,896,138	15,281,039
Leather	2,258	5,209	2,829,234	7,966,514
Food	787	2,621	7,423,580	17,729,944

Totals	30,268	58,508	46,995,062	143,486,675

There were 3,971 establishments in 1872, occupying \$45,164,954 worth of real estate, and employing \$55,265,129 cash capital. The leading interests for the year ending Jan. 1, 1873, were:

CLASS.	No. of Establishments.	No. of Hands.	Cash Capital.	Value of Real Estate Occupied.	Value of Products.
Book and newspaper publishing	62	1,326	\$1,808,000	\$2,500,000	\$2,813,500
Boots and shoes	514	3,554	1,545,093	917,000	3,737,000
Packing boxes	7	146	277,562	47,800	307,575
Bakery products	207	1,232	313,200	437,000	1,623,500

Starch	3	206	310,000	320,000	770,000

Perhaps the most prominent industry is the slaughtering of swine and the packing of pork. Formerly Cincinnati enjoyed a supremacy in this branch, which is now held by Chicago, 1,225,236 swine having been packed in the latter city in 1871-'2, and 917,197 in the preceding year. There are 51 houses in the city that cut and pack pork, besides a large number which purchase green meats for packing or pack elsewhere. The union stock yards, in Spring Grove avenue (nearly completed), occupy 60 acres, 30 of which are covered with houses and pens. The regular packing season extends from Nov. 1 to March 1; but recently summer packing has been carried on extensively. The extent of this industry for 1870-'71 and 1871-'72 was as follows:

WINTER PACKING.

	1870-'71.	1871-'72.
Whole number of hogs packed....	481,560	630,301
Average gross weight, lbs.....	298 84	280
Aggregate gross weight, lbs.....	143,909,390	182,283,061
Average yield per head of lard, lbs.	42 62	41 02
Total yield of lard, lbs.....	20,524,087	25,857,468
Average price paid, gross.....	\$6 65	\$4 86
Aggregate cost.....	\$9,574,004	\$7,956,385
Pork packed, bbls.....		65,777

The whole number packed between March 1 and Nov. 1, 1871, was 87,515, making an aggregate of 717,816 for the season of 1872. In 1872 were manufactured from the product (other than provisions) of hogs slaughtered \$8,436,039 worth of candles, soaps, and oils, \$250,000 worth of bristles and curled hair, about \$100,000 worth of grease and \$125,000 worth of artificial guano; total \$8,911,039. The exports of the product of the hog for the year ending Aug. 31, 1872, were: pork and bacon, \$12,981,151; lard, \$3,531,327; lard oil, \$2,838,810; candles, \$1,799,633; soap, \$494,790; total, \$21,645,717. During the winter season of 1872-'3 the number of hogs packed was 626,305; cost, \$7,492,030; total net weight, 152,766,653 lbs; yield of lard and trimmings, 28,604,877 lbs. The manufacture of iron in all its branches has grown with great rapidity, and promises to take the leading rank in the industrial products of the city. The manufacture of furniture is also increasing rapidly. In 1872, 13,530,973 gallons of lager beer were made from 1,209,249 bushels of barley and 991,235 lbs. of hops; \$4,500,000 capital was invested in this business, and 1,306 hands were employed, at an annual cost of \$1,200,000. Large shipments of this beverage are made to the southern states, the West Indies, and Mexico. The number of gallons of liquor distilled in 1869 was 4,707,440; in 1870, 5,951,120; in 1871, 7,488,796. The number of gallons rectified in 1869 was 9,949,632; in 1871, 13,233,634. In 1873 there were 7 state and national banks, with an aggregate capital of \$4,800,000; 15 private banks, with \$2,300,000 capital; and 2 savings banks with deposits of \$540,000 from 5,522 depositors. There were

24 fire and marine insurance companies, with \$5,000,000 capital, and \$3,360,000 income (1872) from premiums; two life insurance companies, with \$200,000 capital, and \$384,298 income from premiums; one mutual health insurance company, with \$30,175 income from premiums, and \$16,480 losses on risks.—The government of Cincinnati is vested in a mayor elected for two years, with a salary of \$4,000, a board of 25 aldermen, one for each ward, and a board of 50 councilmen, or two for each ward. The board of education consists of 48 members, elected by the people. The courts are: common pleas, of 5 judges; superior, with civil jurisdiction in city cases, of 3 judges; probate, of 1 judge; police court, 1 judge; 10 magistrates' courts; and a district court, with a state supreme judge. The United States circuit and district courts for the southern district of Ohio are held in Cincinnati. The fire department is under the control of five commissioners, who are appointed by the mayor. It is a paid department, employing 158 men, 19 steam fire engines, 1 hand engine, 1 hose carriage, 4 hook and ladder carriages, and 86 horses. There are 228 miles of fire alarm telegraphic lines and 170 signal boxes. The police are under the control of the mayor and 4 commissioners, and their number is limited to 12 captains, 20 other officers, and 300 patrolmen. The city is divided into 10 police districts, each with a station house. In 1872, 12,500 arrests were made. The police telegraph has 20 m. of wire. Water is obtained from the Ohio river. The water works, in East Front street, are of great magnitude. There are four powerful pumping engines, with an average daily capacity of 19,000,000 gallons. The reservoir contains 4,500,000 gallons, and the average daily consumption of the city is about 17,000,000. Two reservoirs, with a capacity of 100,000,000 gallons each, are in process of construction in Eden park. The value of the entire works is \$4,247,557. The total receipts in 1872 were \$610,961. The sewerage of the city was much neglected until about 1870. In 1873 about 30 m. of sewers had been built, some of which were 14 ft. in diameter. The cost of the city government in 1872 was \$4,220,403. Its revenues were \$4,976,544, of which \$3,297,518 was from taxation. The chief expenditures were: for schools, \$717,969; police, \$367,041; redeeming bonds, \$105,760; fire department, \$287,343; street improvements, \$435,484. The bonded debt, April 1, 1873, was \$6,001,500. The tax levy for city purposes for 1869 was \$2 80 on each \$100 of the tax duplicate, producing a revenue of \$3,150,243; 1870, rate \$2 39½, revenue \$3,259,768; 1871, rate \$1 68, revenue \$3,039,100; 1872, rate \$1 51, revenue \$2,643,772. Property in churches, &c., exempted by law from taxation, amounted in 1872 to \$5,029,690, and the value of city property not taxed was \$15,237,194. The increase in the value of property, the rate of tax, and the amount of tax revenue (including

both city and county taxes) are shown in the following statement :

YEARS.	Real Estate.	Personal.	Rate of Tax.	Amount of Revenue.
1880.....	\$3,157,675	\$1,048,529	1-20	\$51,435 00
1840.....	4,731,390	1,440,108	2-45	151,201 00
1850.....	34,194,430	8,668,298	-70	728,666 00
1855.....	60,335,932	24,994,948	1-48	1,262,897 00
1860.....	61,428,917	30,532,458	1-745	1,666,231 00

1870.....	78,736,482	57,370,754	3-16	4,362,197 16
1871.....	123,427,888	56,934,044	2-22	4,004,034 00
1872.....	119,621,886	55,462,410	2-01	3,589,885 40

—The charitable institutions of the city are numerous and very efficient. The Cincinnati hospital, occupying the square bounded by Twelfth street, Central avenue, Ann and Plum streets, is supported by taxation, and has an unpaid medical staff of 14, 6 resident undergraduates, and 68 other employees. In 1872, 3,720 patients were treated, of whom 467 paid for treatment. The daily average of patients was 249. The cost of maintenance was \$90,114 20. From paying patients was received \$12,070. The Good Samaritan hospital, in Locke street (capacity 250 patients), and St. Mary's hospital in Betts street, are private institutions managed by Roman Catholic sisters. The Jewish hospital, in Baum street, cost \$40,000, and is maintained at a cost of \$8,000 annually by the Jewish hospital association. Longview asylum for the insane in 1872 had 818 patients under treatment, with a daily average of 585, all of whom except 14 were treated without charge. A principal and two assistant physicians and 33 nurses were employed. The expenses for the year were \$103,487. It is said to be the best finished and best appointed asylum in the United States. Its grounds are laid out in lawns, walks, and parks, with greenhouses. There are no bars to the windows, and everything prison-like is avoided. The asylum is supported by Hamilton county, which is set off by the state as a district. The city infirmary in 1872 maintained 635 indoor paupers, at a cost of \$35,197; of outdoor poor it relieved 3,674 with provisions and 5,246 with coal, and furnished coffins and interment to 228, at a cost of \$19,923 39. The Cincinnati orphan asylum, maintained by private charity, with accommodations for 300, cared for 102 children, the German Protestant orphan asylum for 108 children. The colored people sustain an asylum with 40 orphans at Avondale. The Roman Catholics sustain two large orphan asylums, under charge of the sisters of charity, and a protectory, where boys are taught trades, under the Dominican brothers. The widows' home, Mount Auburn, receives indigent women not under 60 years old, and in 1873 had 46 inmates; it has property worth \$55,000, and

\$85,500 endowment and trust funds. The Protestant home of the friendless, and the Roman Catholic house of the guardian angel and convent of the Good Shepherd, are female guardian societies, and, except the last-named, afford temporary protection. In 1872 the home of the friendless received 498 inmates, 57 being infants. The house of the guardian angel is a branch of the convent of the Good Shepherd; it boards about 60 girls, and teaches them trades. Both are under the charge of sisters of the Good Shepherd. The children's home in 1872 cared for 274 neglected children. The house of refuge in Mill creek valley, for children under 16 convicted of minor offences, in 1873 had 228 inmates; it is supported by the city, and managed by a board of directors, at an annual cost of about \$50,000. The city workhouse receives adult criminals convicted of minor offences. It is managed by an unpaid board appointed by the mayor and council. In 1872, 4,011 prisoners were committed, of whom all but 317 were discharged; the average number of prisoners per day was 301; the expenses were \$65,732; the services of prisoners let to contractors yielded \$11,118 50. Secret and mutual benevolent societies are very numerous, especially among the German population. The public schools are under the control of a board of 50 members, elected two from each ward in alternate years, and comprise 25 district, 4 intermediate, and 2 high schools, besides a normal school for females, and evening schools. In addition to the ordinary branches, German, music, drawing, and gymnastics are taught in the day schools. According to the report of the superintendent for the year ending June 30, 1872, of the 120,578 persons between 5 and 21 years of age, 27,617 were registered in the public schools; the average daily attendance was 20,048. The total number of teachers was 510, of whom 406 were females. In the 10 night schools there were 55 teachers and 2,952 pupils enrolled, with an average attendance of 1,410. The expenditures for school purposes for the year ending June 30, 1872, amounted to \$746,027, including \$421,241 for teachers' wages, and \$29,457 for night schools. From an average daily attendance of 18,973 for that year, 11,273 were studying German. The two high schools, known as the Woodward and the Hughes high schools, have a wide reputation for efficiency and a high standard of instruction; in 1873 they had 22 teachers and 805 pupils. The tax for schools in 1872 was 2-75 mills city and 1 mill state levy. Of the \$181,000 raised by the state levy, the city received \$169,000, or \$12,000 less than it paid. There are 106 Roman Catholic parochial schools, with an average attendance of 16,165 pupils. The establishment of a free university, to afford liberal and technical training, is in progress, through the bequest of Charles McMicken, estimated at from \$500,000 to \$750,000. A board of 18 trustees has been organized, under whose auspices the McMicken school of design was

opened in 1869, and in 1873 had 5 instructors and 300 pupils. The telescope and property of the Cincinnati observatory, on Mount Adams, had been transferred to the university, and a site of four acres for a new observatory has been donated at Mount Lookout, near Linwood, 6 m. from the city. The Cincinnati Wesleyan college for females, established in 1842, has preparatory, academic, and collegiate departments, and a department of music and of art. In 1872 there were 17 instructors, of whom 11 were females, and 200 pupils. St. Xavier college, conducted by Jesuits, in 1872 had 317 pupils, of whom 145 were in the academic department, 69 in the collegiate, 69 in the commercial, and 34 in the preparatory; 18 instructors, and a library of 12,000 volumes. The college possesses valuable chemical and philosophical apparatus, a museum, and a large mineralogical and geological collection. The Chickering classical and scientific institute, in George street, between Smith and John, one of the largest private schools for boys in the west, has a classical and a scientific course, each of five years, with 14 instructors and 201 pupils. Lane theological seminary (Presbyterian), occupying a site of seven acres on Walnut Hills, was organized in 1829, and had an endowment fund of \$200,000, and a library of 12,000 volumes. In 1873 there were 5 professors and 38 students in the three classes. The medical college of Ohio, founded in 1819, in 1872 had 10 instructors, 226 pupils, and nearly 2,000 alumni. Cincinnati college has been suspended since 1845, excepting its law school, which, with 5 professors, graduates about 30 students annually. Chief among other institutions are the theological seminary of Mount St. Mary's of the West (Roman Catholic), Mount Auburn, young ladies' institute, Cincinnati college of medicine and surgery, Ohio college of dental surgery, Eclectic medical institute, Miami medical college, organized in 1852, and Pulte medical college (homoeopathic), founded in 1872. There are four commercial colleges and two conservatories of music. Cincinnati has 11 public libraries, the most important of which is the so-called public library, occupying an imposing structure in Vine street. It is under the control of a board of seven managers, chosen by the board of education, and is maintained by taxation for the free use of all citizens. The total number of volumes June 30, 1873, was 59,695, the increase during the previous year having been 10,059; 239,487 volumes were taken out by 19,636 persons; average daily circulation, 765. Two large reading rooms on the lower floor are open 14 hours every day in the year, and are supplied with 310 periodicals, including 138 American, 96 English, 60 German, 12 French, 3 Dutch, and 1 Welsh. The reading room, in the third story, is supplied with 42 medical periodicals, and files of 37 current religious newspapers; making, with duplicates, the total number of periodicals received 404, besides 37 newspapers.

The reading rooms were first opened on Sunday from 8 A. M. to 10 P. M., March 12, 1871. The number of Sunday issues for the year ending June 30, 1872, was 19,917. The young men's mercantile library association, founded in 1835, in 1872 had 34,362 volumes and 2,833 members. The increase for the year was 1,282 volumes and 95 active members. The total circulation of books was 59,024. In the reading room may be found 264 magazines and newspapers, of which 45 magazines and 30 newspapers are foreign. The library is open on Sunday. The law library, founded in 1847, contains 7,600 volumes. The mechanics' institute library has 6,500 volumes, and a reading room. The Ohio philosophical and historical society has a library of 4,500 bound volumes, and 12,000 pamphlets and unbound volumes. There are six large musical associations, seven dramatic and reading clubs, and one literary club. The natural history society, recently organized, has a fine cabinet, and the nucleus of a library and a building fund. The historical and philosophical society, organized Dec. 31, 1831, has apartments in College building. Its object is to collect and preserve materials for American history, and it has 87 members. The chamber of commerce, merchants' exchange, an influential and powerful commercial organization, of 1,200 members, meets daily; the board of trade, 850 members, composed of manufacturers; the mechanics' institute, composed largely of machinists, and the pork packers' association, are important organizations. Besides these, nearly every considerable branch of business has its own organization. Under the management of a board appointed by the chamber of commerce, board of trade, and mechanics' institute, three successive industrial expositions have been held yearly, the last in September, 1873. The buildings cover $3\frac{1}{2}$ acres of ground in the heart of the city, and have 7 acres of space for exhibiting. The young men's Christian association occupies a building in Vine street, containing free reading, conversation, and amusement rooms. Daily religious services are held here, and free lectures and concerts are given. Here also are a free employment agency, and a boarding-house directory. In 1872 the total attendance was 63,539. The chief places of public amusement are Pike's opera house, Mozart hall, Robinson's opera house, Hopkins music hall, National theatre, and Wood's theatre. There were 75 newspapers and periodicals published in Cincinnati in 1873, as follows: 9 daily, of which 3 were in German; 1 semi-weekly; 42 weekly, including 4 German; 21 monthly, including 1 German, and 1 quarterly. There are 160 church edifices in the city, distributed as follows: Baptist, 14; Christian, 2; Congregational, 4; Disciples of Christ, 4; Friends, 2; German Evangelical Union, 4; German Reformed, 3; Independent Methodist, 1; Hebrew, 5; Lutheran, 4; Methodist Episcopal, 26; Methodist Protestant, 3; Calvinistic Methodist, 1;

African Methodist, 1; New Jerusalem, 1; Presbyterian, 16; United Presbyterian, 3; Reformed Presbyterian, 3; Protestant Episcopal, 11; Roman Catholic, 32, and 12 chapels; United Brethren in Christ, 3; Universalist, 1; Unitarian, 3; Union Bethel, 1.—Cincinnati was first settled in 1788, by emigrants from New Jersey, on land purchased from the United States government by John Cleves Symmes. Fort Washington was soon built on the crest of the second plateau, between the present Lawrence and Ludlow, and Pearl and Fourth streets. The village was laid out early in 1789 by Col. Israel Ludlow, and was mainly built below the fort, on the river bank. For many years it was composed of frame and log houses. It is said that the name was suggested by Gen. St. Clair, in honor of the Cincinnati society of officers of the revolutionary war, of which he was a member. In 1790 Hamilton county was organized by Gen. St. Clair, with Cincinnati as the county seat. After the victory over the Indians by Gen. Wayne, at the battle of Fallen Timbers, in 1795, which gave peace to the Miami country, immigration rapidly increased, and the growth of the village was steady. Emigrants descended the Ohio river from Fort Duquesne (now Pittsburgh) in flat boats or arks, the journey being attended with great peril from hostile Indians on either shore. In 1794 a line of two keel boats pushed by poles, with bullet-proof covers and port holes, provided with cannon and small arms, was established between Cincinnati and Pittsburgh, making the trip once in four weeks. The keel boat was the best and most comfortable boat for navigation on the Ohio, and this and the flat boat were the sole means of conveyance on the waters of the Ohio and Mississippi. In 1811 the first steamboat was launched in the west, and in 1816 the first steamboat was built in Cincinnati. The steamboat changed the whole kind and character of navigation on the Ohio. Cincinnati at once began to build steamboats, and to trade with the most distant parts of the Mississippi valley. It was incorporated as a city in 1814, and became the mart of a vast commerce, and the point for the receipt, distribution, and transshipment of the immense surplus products of the great region to which she was a centre. Since 1816 the building of river boats has been extensively carried on. During the 25 years ending with December, 1872, 655 steamboats and barges were built, with an aggregate burden of 223,477 tons. The Miami canal was built in 1830, and in 1840 the Little Miami railroad was constructed. In September, 1862, martial law was for a brief period declared in the city, when an attack by confederate troops was expected. The territorial extent of the city, which was formerly about 7 sq. m., has been recently much increased by the following annexations: Feb. 24, 1870, Storrs township, 3 sq. m.; Mount Auburn and Corryville, 1 sq. m.; and Walnut Hills, $\frac{3}{4}$ sq. m.; May 9, Lick Run and Camp

Washington, 5 sq. m.; Pendleton and Spencer township, $2\frac{1}{2}$ sq. m.; Feb. 1, 1873, Columbia village 1 sq. m.; March 18, 1873, Cummins-ville, $2\frac{1}{4}$ sq. m.; March 28, Woodburn, 1 sq. m.

CINCINNATI, Society of the, an association founded by the officers of the American revolutionary army after the peace of 1783. Its object was to commemorate the success of the revolution, and to perpetuate sentiments of patriotism, benevolence, and brotherly love, and the memory of hardships experienced in common. The original draft of its constitution was made by Gen. Knox, and is still extant. The meeting for the organization of the society, held at the quarters of Baron Steuben in New York, on the Hudson river, was composed of the general officers in camp and regimental delegates from the respective lines, the baron presiding as senior officer. Appropriate badges and ornaments were devised, including the eagle and uniting the colors blue and white in compliment to the combined arms through which the revolution had been achieved. The honors of life membership were conferred upon a number of French officers. A fund was formed by the contribution of one month's pay for the relief of members in needy circumstances. The constitution adopted in 1783 declared that the "officers of the American army" associated "themselves into one society of friends, to endure as long as they

Badge of the Society of the Cincinnati.

shall endure, or any of their eldest male posterity; and in failure thereof, the collateral branches who may be judged worthy of becoming its supporters and members." Jealousy arose against the society, which was supposed thus to be establishing a military order, with the absolute right of inheritance on the principle of the laws of primogeniture. At the first general meeting of the society, held in Philadelphia in May, 1784, a proposition was made to amend the constitution, abolishing all succession of membership, and confining the society to those who had served during the war of the revolution. The amendments then proposed were submitted to the several state societies, but failed to receive their assent, and the constitution as originally adopted remains in force. The right of succession is not absolute, but subject to the judgment of the society that the son, or next in order of descent to a deceased member, is "worthy of becoming a supporter and member;" so that the

law of inheritance confers only the right to be voted for, and the society admits or declines to admit according to its estimate of the character of the eldest male descendant. If he be deemed not worthy, the right is held in abeyance. The impression prevailed in the public at large that the germ of an hereditary aristocracy was concealed within the society, and in some of the states charters were for that reason refused to the branch societies. At the second general meeting, held in 1787, Washington was elected president-general, and was reelected triennially during his life. He was succeeded by Hamilton and the Pinckneys, and the society was in all its vigor during the visit to the United States in 1824-'5 of Lafayette, who was its only surviving major general. The societies of Pennsylvania and Massachusetts had acts of incorporation. The Connecticut society was dissolved in 1804, after a patriotic valedictory by Col. Humphreys. The Delaware society was dissolved about the same time, the more attached of the members carrying their share of the funds into the Pennsylvania society. The New Hampshire, Rhode Island, and Virginia societies continued to exist nearly as long, the first, upon its discontinuance, depositing its records in the state historical society, and the last named appropriating its funds toward the endowment of Washington college. The Georgia society also was discontinued, bequeathing its funds to the parent society. Robert Burnet of New York, who died in 1854, was the last survivor of the original members of the association. It has at present six state branches, which hold annual meetings on the 4th of July, viz., Massachusetts, Maryland, New York, New Jersey, Pennsylvania, and South Carolina. The general society meets triennially, and its conventions have been held successively at Philadelphia, New York, Baltimore, Charleston, Trenton, and Boston. Among the earlier honorary members of the Cincinnati of Pennsylvania were Benjamin Franklin, Sharp Delany, and Robert Morris; among those of New Jersey were Elias Boudinot, William Livingston, and Frederick Frelinghuysen; among those in New York were Chancellor Livingston, Gouverneur Morris, Rufus King, Stephen Van Rensselaer, the naval commanders Bainbridge, Biddle, Stewart, Hull, and Perry, and Generals Jackson, Scott, Brown, Cadwallader, Taylor, Worth, Wool, Grant, and others. The best accounts of the society are in the "North American Review" for October, 1853, and in the "Memoirs of the Pennsylvania Historical Society," vol. vi.

CINCINNATUS, Lucius Quintus, a Roman senator, born about 519 B. C., died after 439. He was a rich patrician, and was occupied with the cultivation of his estates at the time when Terentius Arsa commenced his demands for the enactment of written laws which should be binding upon the patricians and plebeians alike (462). These demands gave rise to great disturbances, and Cæso, son of Cincinnatus,

took an active part in them on the side of the patricians. One Marcus Volscius, a plebeian, testified that Cæso knocked down his brother while he was feeble from sickness, and injured him in such a manner that he died. Upon this evidence Cæso was convicted, and according to Livy Cincinnatus was compelled to pay such a heavy fine on his account that he was ruined. The resistance to the passage of the Terentilian law was kept up by the patricians, and in the course of it Herdonius (460) took possession of the capitol with a band of outlaws and slaves. The citizens attempted to recover possession of it, and in the conflict that resulted the consul, Publius Valerius Publicola, and Cæso were killed. Cincinnatus was appointed consul in the place of Publicola. He was embittered by the loss of his son, and opposed with great violence the enactment of the Terentilian law. When his consulship expired he retired to a small estate beyond the Tiber which belonged to him, and devoted himself to its cultivation. In 459, the patricians then being in the ascendancy, Marcus Volscius was accused of having borne false witness upon the trial of Cæso. In 458 the Æqui and Volsci resumed war against the Romans. Lucius Minucius, the Roman consul, with all his army, was shut up in a defile and hemmed in by the enemy on all sides. Five horsemen broke through, and brought news of what had happened to Rome. It was resolved that Cincinnatus should be created dictator. Messengers were sent by the senate to inform him of his appointment. They found him at work in his field, clad in his tunic. He called his wife, Racilia, and bade her bring him his toga, in order that he might receive the message of the senate clothed in the garb of a Roman citizen. He accepted the office, and made Lucius Tarquitius, a patrician, master of the horse. He raised an army by making a general levy of all the citizens, and marched to the relief of the consul. He surrounded the enemy in turn, so that they were in a ring between the consul's army and his own, and were compelled to capitulate. In this manner Cincinnatus saved the state within 24 hours. Such is the account given by Livy; but Niebuhr and other modern historians have shown that the legend is destitute of truth. While Cincinnatus was dictator, the trial of Marcus Volscius for bearing false witness came on for hearing at the comitia, and Cincinnatus presided over it. Marcus Volscius was compelled to go into exile. In 439 L. Minucius Augurinus, *præfectus annonæ*, charged Spurius Mælius, a rich plebeian knight, with seeking to make himself king. Thereupon Cincinnatus, then 80 years of age, was again appointed dictator. Caius Ahala was appointed master of the horse. The capitol and other strong places were garrisoned by the patricians. Ahala sent an officer to bring Mælius before the dictator, but Mælius kept the officer at bay with a butcher's knife, and took refuge in the crowd. Ahala, at the head

of a band of patricians, rushed into the crowd and killed him. Though the dictator himself had not power to put Mælius to death, but only to bring him before the *comitia centuriata* for trial, Cincinnatus and all the patricians approved of the act. Ahala was however afterward brought to trial, and only escaped condemnation by voluntary exile. At the end of 21 days Cincinnatus retired from the dictatorship and returned to his farm.

CINEAS, a Thessalian, the minister of Pyrrhus, king of Epirus. He possessed great oratorical powers, and Pyrrhus said that his eloquence had won him more cities than his own arms. The most remarkable episode of his life was his being despatched by Pyrrhus to Rome after the battle of Heraclea (280 B. C.), to offer the Romans peace. His wonderful memory enabled him to address all the Roman senators by name; and although the terms which he offered were hard, his persuasive power was so great that he would perhaps have succeeded had he not been defeated by the eloquence of old Appius Claudius the Blind. On his return he told Pyrrhus that the city of Rome was like a temple, the Roman senate an assembly of kings, and that to fight with the Roman people was to fight with the Hydra. In 278 he was again sent to Rome with an offer of more favorable terms, and was successful. He then went as ambassador to Sicily, and is supposed to have died there.

CINGALESE LANGUAGE (more correctly *Sinhalese*), a language spoken in the interior of Ceylon and on its southern coast. The name is derived from *Sinhabahu* (lion-son) a king of Ladha on the Ganges, whose son Vijaya (Victory) founded the kingdom of Ceylon in the 6th century B. C. This was called *Sinhadvipa* (lion isle), and by the Chinese *Sze-tse-kwō* (lion kingdom). The language is a modification of the aboriginal Elu by the Sanskrit, with a slight tinge of Malay, and has many dialects. The language of religion and of learning is the Pali. Deveni Paetissa, the ninth king, becoming a Buddhist, introduced writing in the beginning of the 4th century B. C., and Pali books were brought in under Manamraja, the fifth king of the *Sūryya-vansa* (Sun dynasty, 5th century A. D.), or earlier. The Cingalese has degenerated so much that there is now a material difference between the vernacular and the written language. The latter is copious, has a regular grammar, and is capable of elegant style, although its pundits disagree in orthography. The graphic system of the Cingalese is the Devanāgarī, but the figures of the letters are serpentine and slender, resembling the Pali. The 50 letters (8 vowels, 8 diphthongs, and 34 consonants) represent only 30 sounds (7 vowels and 23 consonants), because some only occur in Sanskrit words, and some cannot be distinguished by the ear. Our transcription is Italian as to vowels, and English as to consonants, excepting *g*, which is always hard.—There are three genders: mascu-

line nouns end mostly in *a*, plural *o*, *an*, *aru*; feminine in *i*, plural *u*, *varu*; neuter in *a*, *u*, plural adding *val* or dropping the final syllable (thus: *nuvaraval*, cities; *kadu*, swords, from *kaduva*). The principal masculine and feminine case endings are: genitive, *gē*, *nē*; dative, *ta*, *da*; accusative, *va*; ablative, *gen*, *nen*; there is no *gē*, *gen* in the plural, but only the other terminations. Neuter endings of both numbers are: *ē*, *ata*, *ava*, and *en*, of the above named four cases respectively. Examples: *manuspayā*, homo; *gūnī*, mulier; *oluva*, caput; genitive, *manuspayāgē*, hominis; *gūnīgē*, mulieris; *oluvaē*, capitis; dative, *manuspayāta*, homini, &c.; accusative, *gūniva*, mulierem, &c.; ablative, *oluwen*, capite, &c., as above detailed; plural, *manuspayo*, homines; *gūnivu*, mulieres; *olu*, capita; *manuspayinnē*, hominum, &c., respectively, as pointed out. Adjectives are indeclinable and precede the substantives; thus: *sonda pīrimiyā*, bonus vir. Comparative particles are: *bohoma*, much; *vadā*, more; *atī*, most; thus: *vāda naraka*, worse; *atī sudu*, wisest; *sarīrayata vadā sonda prānaya* (body-than more-good soul), corpore melior anima (est). Numerals: *ekay*, 1; *de kay*, 2; *tunay*, 3; *hatary*, 4; *payhay*, 5; *hayay*, 6; *hatay*, 7; *atay*, 8; *nevayay*, 9; *dahayay*, 10; *vissay*, 20; *tihay*, 30, &c.; *siayay*, 100; *dahay*, 1,000. Ordinals: *palamu-veni*, 1st; *de-veni*, 2d; *tun-veni*, 3d, &c., suffixing *veni* to the cardinals, with some alterations. Pronouns personal: *mama*, ego; *mangē*, mei; *mata*, mihi; *māva*, me; *mangen*, a me; *api*, nos; *apagē*, nostri; *apata*, nobis; *apava*, nos; *apagen*, nobis. There are 14 terms in addressing the second person, regulated by the rank both of the speaker and of the person addressed, according to strictest etiquette; for instance, a person of the lowest caste is *to*, masc., *ti*, fem. (thou, you); a son or pupil is *umba*; an equal is *tamunnuku*, and somewhat respectfully *tamunsē*; a superior is *tamunvahanṣē*; the highest person is addressed by *etanavahanṣē*; with other varieties, all equivalent to thou and you, but modified by case and number. The third person is spoken of or pointed out with fewer variations. The verbs are very peculiar; those of the Elu being radical and simple, but those derived from Sanskrit being nouns verbified by certain auxiliaries. Prepositions and postpositions, conjunctions and adverbs are numerous. Nouns and infinitives of verbs are often joined, both receiving a final *i*, thus: *gandat*, *dendat*, in order to take and to give; or *ut* after consonants, thus: *vachanavalut kriyāvalut*, to become and to act.—The Cingalese literature, being chiefly Buddhistic, has suffered very much from the intolerance of the Brahmans, who speak Tamulic and are Malabars. King Parakramabahu restored the sacred books in 1195, partly by the memory of priests, partly by new composition. Besides their own books, they also translated some scientific Sanskrit Brahmanic works, which they call *Sanna*. There are also versions into Elu

from the Pali, for instance the *Elu Atuvāvas*, or comments on Buddha's life and doctrines. The *Bana* are sermons of Buddha. There are very many books on botanical medicine, many on astronomy, some of a rhetorical and poetical character, a few historical and lexicological. The *Rājāvali* (*rājā*, king, and *āvali*, line), a history of the kings of Ceylon, translated by Albert Johnston, Joinville, Davis, and Mahony, and the *Amaracōsha* (*amara*, immortal, and *kōsha*, issue, bud, &c.), or in Cingalese *Amarasinha* (the author's name), a dictionary, with a copious Cingalese commentary, are Sanskrit works. See also *Singalsche Taal Konst* (Grammar), by J. Ruell, Amsterdam, 1708; a short grammar by David Wilkins (in the preface to Chamberlayne), who obtained the pronunciation from Pieter Croenenburg; "Dictionary of English-Cingalese and Cingalese-English," by the Rev. B. Clough (2 vols., Colombo, 1821-'30); *Mahāvānsa*, an epos in Pali, translated by Turnour; *Essai sur le Pali, la langue sacrée de la presqu'île du Gange*, by E. Burnouf and Christian Lassen (Paris, 1826).

CINNA, Lucius Cornelius, a Roman consul, killed at Brundisium in 84 B. C. He was the son of Lucius Cornelius Cinna, who was consul in 127. Although a patrician by birth, he belonged to the party of Marius and the plebeians. When the election for consuls came on at Rome in 88, the power of Sulla was in the ascendancy, and he favored the election of Nonius and Servius Sulpicius. The people nevertheless elected Cinna and Cneius Octavius. One of Cinna's first acts after entering into office was to induce the tribune M. Virgilius to prefer charges against Sulla. But Sulla disregarded them, and went on with his preparations for the Mithridatic war. Before setting out for it he obtained from Cinna a promise that he would not during his absence attempt any change in the constitution. No sooner had Sulla departed, however, than Cinna endeavored to obtain the passage of the Sulpician law for the incorporation among the 35 tribes of those of the allies who had been made Roman citizens. This was a measure which if adopted would have strengthened the power of the plebeians. The consuls resorted to force for the purpose of carrying it through; but they were resisted by Octavius, and after a severe conflict in the forum they were defeated and driven out of the city. The senate passed a decree depriving Cinna of his citizenship and of his office as consul. Cinna appealed to the new citizens of Italy, and organized an army. Marius received intelligence of what had taken place and returned from Africa. Cinna and Marius together prosecuted the war with great energy. The corn ships were captured and the supplies of food destined for Rome were cut off. The senate was obliged to yield, and sent a deputation to Cinna and Marius, inviting them into Rome. Cinna received the deputation with courtesy, sitting in his chair of office, Marius standing by in ominous silence. They after-

ward entered the city with their guards. Marius showed much greater resentment than Cinna. His guards killed every one they met whom Marius did not salute. Great numbers of the patricians were slain. Marius and Cinna proclaimed themselves consuls for the following year, 86. Eighteen days after the commencement of their term Marius suddenly died of pleurisy, and Cinna chose Lucius Valerius Flaccus as his colleague. Flaccus was sent into Asia to oppose Sulla, and was murdered there. For the year 85 Cinna selected for his colleague Cneius Papirius Carbo. Cinna and Carbo called on the new citizens throughout Italy for men, money, and provisions with which to carry on the war against Sulla. The senate endeavored to stop these proceedings, but though Cinna and Carbo professed to be willing to obey the senate, they in fact went on with their preparations for war, and proclaimed themselves consuls for another year. They resolved to transport an army into Greece and encounter Sulla there, and had embarked one detachment when the soldiers mutinied and Cinna was killed. Cinna at the time had every reason to anticipate success, as he and his colleague were supported by the new citizens, and they had an army very much larger than that with which Sulla a short time afterward landed at Brundisium.

CINNABAR. According to Pliny, this is an Indian name given to a mixture of the blood of the dragon and elephant, and to other substances which produce a similar color. It was afterward applied to the common ore of mercury, the sulphuret, on account of its blood-red color. The ancient Romans were probably acquainted with this ore of mercury, for the mines of Almaden, near Cordova in Spain, which still produce it, are known to have been worked nearly 3,000 years ago; and both Pliny and Vitruvius refer to the ore of mercury in amalgamating gold. The name is also given to an artificial preparation, identical in composition with the ore. Cinnabar consists of 1 atom of mercury, the chemical equivalent of which is 200, and 1 atom of sulphur, 32; or per cent., 86.2 of mercury and 13.8 of sulphur. It forms beds and veins in the upper secondary and older stratified rocks, and is also met with in granite and porphyry. The strata near the veins often contain the ore disseminated through them. It crystallizes in rhombohedral forms, possesses an adamantine lustre, and a brilliant red color, passing from cochineal to ruby red. Its hardness is from 2 to 2.5; its specific gravity is 8.998. It sublimes at a red heat, and without decomposition if protected from the air; and when mixed with iron or lime in retorts, the sulphur is retained and the mercury volatilized. When finely ground, it becomes of a very lively red, and in this condition is known as vermilion. The most important mines of native cinnabar are those of Almaden, already referred to, of New Almaden in California, of Idria in Austria, and of Huanca Velica in Peru.

In Hungary, Bohemia, Bavaria, China, Japan, and Brazil, the ore is also worked.—Artificial cinnabar, from which the greater part of the vermilion used in the arts is prepared, is made by subliming an intimate mixture of 5 or 6 parts of mercury and 1 of sulphur. The mercury is introduced and stirred into melted sulphur. When the mixture becomes thick, combination suddenly takes place, attended with violent crackling and movement of the mass, and evolution of light and heat. The blackish red product is pounded to powder and mixed with a little sulphur. A glass flask half filled with it, and loosely closed with a charcoal stopper, is partially buried in a sand bath, and kept at a red heat for some hours. The excess of sulphur passes out of the flask, and the cinnabar sublimes and condenses in its upper part, leaving the fixed impurities in the bottom. It is then broken up and ground with pure water as finely as possible, and finally dried. The finer the powder is made, the more beautiful is the color. In Idria the process is somewhat different, mercury being thoroughly intermixed with powdered sulphur by placing them together in casks, which are made to revolve. In a few hours a brown powder is produced, which is heated and sublimed in cast-iron vessels. The Chinese have still another process; and their cinnabar is said to incline to a carmine color, while all the European has a yellow tinge. These processes are all in the dry way; but the substance is also prepared in the wet way by the action of the alkaline hydrosulphites upon the black sulphuret of mercury, which is obtained by passing sulphuretted hydrogen through a solution of some mercurial salt. The finest artificial product is obtained by Brunner's process. Mercury, 100 parts, is triturated with 38 parts of sulphur, till the whole is converted into Æthiops mineral (a black compound of the two substances). This is placed in a solution consisting of hydrate of potash in 6 parts of water, and kept at a temperature varying little from 45° C., with constant stirring at first. As the water evaporates it is replaced. The reddening usually begins in about 8 hours. The heat must not then rise above 45° C. When the color is the brightest it is allowed to cool slowly. It is then washed and freed from the metallic mercury. From 109 to 110 parts of cinnabar to 100 of mercury is the product. Vermilion is adulterated with brick dust, oxide of iron, red lead, and dragon's blood. The last is detected by its empyreumatic odor on applying heat; the others by their remaining behind when the pigment is ignited.

CINNAMON, the inner bark of the cinnamon tree (*Laurus cinnamomum*), which appears to have been known at a very early period. The spice obtained from it was used by the Hebrews in their religious ceremonies (Exod. xxx. 23). The Arabian merchants trading between the Red sea and the East are supposed to have carried supplies of it within the range of Phœnician and Grecian commerce. The

tree is a native of Ceylon, where it grows to the height of 20 or 30 ft. It grows also in China and South America. The bark was originally collected from the tree in a natural state, as the Cingalese gave no attention to its cultivation and improvement. Not much was done toward its cultivation until the Dutch came into possession of the island, when, by clearing off the underbrush and weeds and thoroughly draining the lands, a finer quality of bark was produced. The cinnamon gardens, as they are called, cover an extent of 12,000 acres, the yield ranging between 50 and 500 lbs. per acre. For a long time the Dutch government monopolized the trade in this spice, in which period it was greatly extended. Amsterdam being the sole mart for the product, the supplies sold in that city were immense, averaging from 1692 to 1792 about 320,000 lbs. per annum. After the British came into possession of Ceylon, the cinnamon trade fell

Cinnamon.

into the hands of the East India company, by whom it was monopolized until the year 1833. It was then thrown open, but heavy duties were levied on the exportation. Cinnamon from Java a few years later, as also the cassia from China, coming into competition with the Ceylon spice, the duties have been much reduced, though the last named is superior to any other variety. The soil of Ceylon, being light and sandy, is particularly adapted to this culture. The trees are raised from the seed, and will in six or seven years afford shoots fit for peeling. There are two harvesting seasons in the course of the year: the first and principal crop is procured in May and June, the second in November. Trees two centuries old continue to bear abundantly. The "peelers," as they are called, belong entirely to the Chalia caste, and become by practice very skillful. The bark, after being taken in strips about 40 inches in length from the trees, is collected in bundles for the purpose of fermentation, the

epidermis being easily removed. It is then slowly dried, rolling up in the form of a quill. It is assorted according to its quality into three varieties; the inferior kinds not worth exporting are used in preparing the oil of cinnamon, which is obtained by distillation. The best stick cinnamon is almost as thin as paper, of a light yellowish brown color, and of a sweet aromatic taste. That most esteemed is produced from the late government gardens in Ceylon, which since 1840 have been sold to private capitalists. That least valued comes from the forests.—Cinnamon is used medicinally as an aromatic and moderate astringent. It contains a small quantity of tannin, upon which its astringency depends. Though seldom prescribed alone, it enters into many official preparations. The oil is used in perfumery, pharmacy, and sometimes instead of the spice. Ground cinnamon is frequently adulterated with cassia (which is often substituted for it), and with baked wheat flour, sago meal, or East India arrowroot. The adulteration is not difficult of detection. The Chinese cinnamon, which is the product of the *cinnamomum cassia*, is properly called cassia; but it is often designated by the name of the superior article, and sold as cinnamon. Sometimes it is found little inferior to the real cinnamon.—The imports of cinnamon into Great Britain for 1870 amounted to 2,215,434 lbs., valued at \$1,264,375; for 1871, to 1,584,638 lbs., valued at \$720,730. Of the imports for 1871, 18,512 lbs. were from Egypt, 75,413 from China, 1,430,518 from Ceylon, and 60,195 from other countries. Nearly the entire export from Ceylon is to Great Britain.

CINNAMON STONE, a variety of garnet of a cinnamon brown shade. It is found at numerous localities in the metamorphic rocks in this and other countries. That brought from Ceylon is used in jewelry. (See GARNET.)

CINO DA PISTOJA, an Italian poet and jurist, whose real name was GUIRONCINO or GUITONE, born at Pistoja in 1270, died there, Dec. 24, 1336. He belonged to the noble Sinibaldi family, and became a judge at Pistoja, whence he fled in 1307, during the conflict between the parties of the white and the black. He was a prominent Guelph, and a friend of Petrarch and of Dante, who often makes complimentary allusions to him. He employed his exile in missions for his party in Lombardy and France, went with the army of the emperor Henry VII. to Rome, and subsequently held an office in Naples. Still later he taught jurisprudence at Treviso, Perugia, and Florence. His first innamorata, Sebraggia, who died soon after he married her, became the theme of his poetry, which ranks next to that of Petrarch. Subsequently he celebrated in song the marchioness Malaspina, whose family is often gratefully referred to by Dante. The most complete collection of the *Rime di Messer Cino*, or *Poesie* (Rome, 1559), was published by Campi in Pisa (1813; new ed., 1826), and the most recent is

by Carducci (Florence, 1864). His commentary on Roman law, *Lectura Cini de Pistoria super Codice* (Pavia, 1483, and Lyons, 1526), passed through many editions.

CINQ-MARS, **Henri Coiffier de Ruzé**, marquis, a favorite of King Louis XIII. of France, born in 1620, beheaded at Lyons, Sept. 12, 1642. His father, the marquis of Effiat, was indebted for his fortune to Cardinal Richelieu, who also chose the son as a companion for the king. The young man ingratiated himself so much into the affections of his sovereign, that he was appointed grand master of the wardrobe and of the horse. He aspired not only to have a share in the government, but also to the hand of the beautiful Maria de Gonzaga, princess of Mantua, who afterward became queen of Poland. The cardinal made light of his pretensions, but Cinq-Mars took offence at this contemptuous treatment and resolved to resent it. In conjunction with several discontented noblemen, he opened negotiations with Spain; but Richelieu succeeded in procuring a copy of their agreement, brought it to the knowledge of the king, and obtained an order for the arrest of his favorite. Cinq-Mars was thrown into prison in company with his youthful friend De Thou, a councillor of the parliament of Paris, and both were sentenced to death, and beheaded at Lyons.

CINQUE PORTS, the five English channel ports of Hastings, Romney, Hythe, Dover, and Sandwich, on the S. E. coast of England, to which were afterward added the towns of Winchelsea and Rye. These ports, lying opposite to France, received peculiar privileges in the early days of English history, on condition of providing in time of war a certain number of ships at their own expense. According to Camden, the first warden was appointed by William the Conqueror; but their charters are traced to the times of Edward the Confessor. They are governed by an officer called the lord warden of the cinque ports. Formerly each of them sent two members to parliament, under the title of barons of the cinque ports; but since 1831 this privilege has been restricted to Hastings, Dover, and Sandwich. The duke of Wellington was lord warden of the cinque ports, and died at the official residence, Walmer castle.

CINTRA, a town of Portugal, in the province of Estremadura, on the edge of a granitic sierra, which forms a continuation of the Estrella range, 15 m. W. N. W. of Lisbon; pop. about 3,000. It is a place of resort for the wealthy inhabitants of the capital, and for English and other foreigners, whose villas are scattered over the neighboring slopes, and stud the beautiful valley of Collares, west of the town. Fruits of every description abound in the surrounding country; the climate is mild and pleasant; and the scenery, though perhaps surpassed in other parts of Portugal, has been made famous by Byron's glowing description of it in "Childe Harold." The kings of Por-

tugal have a palace here, which was formerly the residence of the Moorish monarchs. In it Alfonso V. was born and died, and Alfonso VI. was confined during the last eight years of his life. On the summit of one of the highest peaks of the sierra is the Penha convent, built by Emanuel the Great, and restored and beautified for use as a palace by the ex-king Ferdinand. There is another convent built for the reformed Franciscans by De Castro, and called the "convent of cork," from the circumstance of the cells being lined with that substance. It is partly hollowed out of the rock. The residence of De Castro, and a chapel built by him after his return from India in 1542, are shown to visitors. In the vicinity of the town are quarries of beautiful marble. On Aug. 30, 1808, a convention was concluded here by the English commander, Sir Hugh Dalrymple, with Gen. Junot, after the defeat of the French at

as the initials of a name engraved upon carriages, furniture, plate, seals, or tombs, which it was formerly the custom of tradesmen and citizens to display, much as a coat of arms was displayed by the nobility; also to the monogram or conventional figure by which some artists have designated their names upon their works.—It is also the name of any disguised method of writing, designed to be understood only by the persons who have especially agreed upon the significance of the characters employed. The oldest example of this is the Spartan *scytale*. When the general of the army departed on any expedition, he took a round wooden staff, called a *scytale*, with him, leaving another exactly like it with the ephors. When the latter had any communication to make to him, they wound a slip of parchment around the staff, and on this wrote the message. Being unrolled, only detached and fragmentary

The Penha Convent.

Vimieiro, under which they were not only permitted to leave Portugal, but were conveyed to France with their arms and property.

CIONE, Andrea di. See ORCAGNA.

CIOTAT, La, a seaport town of France, in the department of Bouche-du-Rhône, on the railway from Marseilles to Toulon, 14 m. S. E. of Marseilles; pop. in 1866, 10,017. The port is accessible to vessels of 300 tons. It has a large parish church, a fine public promenade, a steam engine factory, considerable ship building, and an extensive coasting trade.

CIPHER (Arab. *sifr*, empty), one of the ten characters used in the notation of numbers by the Arabic system. When it stands by itself it signifies zero. Each cipher placed at the right of a significant figure representing a whole number increases its value tenfold. In decimal fractions every cipher that is placed before a significant figure reduces it to one tenth its previous value.—The term is also used for an enigmatical intertexture of letters,

letters appeared; but when sent to the general he was able to put it in position upon his staff and read it. The art of secret writing in modern times was long regarded as a branch of magic. When the abbot Trithemius published a treatise on it about 1500, the elector palatine caused a copy of it to be burned, as containing diabolic mysteries. More recent writers on the subject are Giambattista Porta, Vigenère, J. P. Niceron, Kluber (Tübingen, 1809), and Martens (Leipsic, 1851). The chief use of cipher writing since the time of Richelieu has been in

diplomatic correspondence, employing various methods, by figures, letters, and catchwords. The introduction of the electric telegraph in recent times has also given occasion for the use of commercial ciphers, by which merchants and bankers transact distant affairs without betraying their secrets.

CIRCARS, Northern, an old division of the presidency of Madras, British India, on the E. coast of the peninsula, between lat. 15° 40' and 20° 17' N., and lon. 79° 12' and 85° 20' E., bounded N. and W. by Orissa, S. by the Carnatic, and E. by the bay of Bengal; area, 23,750 sq. m.; pop. about 3,000,000. The division formerly comprised five districts, called circars, viz.: Cicacole, Rajahmundry, Ellore, Condapilly, and Guntoor, the territory embraced in which was afterward distributed among the British districts of Guntoor, Masulipatam, Rajahmundry, Vizagapatam, and Ganjam. A range of mountains runs along the W. frontier, supporting a growth of valuable

teak and other timber, and leaving between their base and the coast a fertile tract of 30 or 40 m. average breadth, in which grain and a superior kind of tobacco are produced abundantly. Sugar, ginger, turmeric, and cotton are also cultivated; but fruits and green esculents are scarce. Sheep and the larger species of horned cattle are the principal quadrupeds. Ship building is carried on in the Godavery river; the coasting trade with Madras and other ports employs a large number of native vessels; cotton stuffs, chintzes, carpets, punjum cloths, muslin, silks, and indigo are manufactured; and fine cotton fabrics are exported to England. The native inhabitants are almost without exception Hindoos, and as a class are thought to be superior to the Bengalese. Their villages are little better than collections of large mud huts. Four of the Circars were acquired from the emperor Shah Alum, who bestowed them upon the East India company as a free gift in 1765; Guntoor, the fifth, passed into British hands in 1788.

CIRCASSIA (properly **TCHERKESSIA**; called by the Circassians the land of the Adighei), a mountainous region of European Russia, forming a part of the Kuban district, between lat. $42^{\circ} 40'$ and $45^{\circ} 20'$ N., and lon. $37^{\circ} 30'$ and $42^{\circ} 30'$ E.; area, about 20,000 sq. m.; pop. about 300,000. It is situated on the N. E. part of the Black sea to about lon. $42^{\circ} 30'$ E. On the N. it is separated from the territory of the Black sea Cossacks by the river Kuban, and on the N. E. by its affluent, the Laba, from the Nogai lowlands; on the S. E. it borders on the Greater Kabarda; and on the S. and S. W. it is separated from Imerethia, Mingrelia, and Abkhasia by the highest chain of the Caucasus. The whole of this country, with the exception of the low lands on the Kuban, is rugged and mountainous, embracing the Elburz and other peaks of the Caucasus, and is everywhere broken into deep valleys and intersected by streams. Toward the N. W. the mountains gradually decrease in elevation, and the range of the Black mountains (anc. *Coraxici Montes*), between the Black sea and the Kuban, consists of a number of rounded hills of moderate height. From the contiguity of the mountains to the sea the watercourses are generally of small importance, most of the rivers being but shallow streams, which in summer stagnate on the low grounds and produce miasma. In the more elevated portions the atmosphere is colder and the climate is more salubrious. The hydrography is of two systems, the waters of the S. E. district being conveyed by the Terek to the Caspian sea, and those of all other parts by the Kuban or directly to the Black sea. Some of the direct affluents of the Black sea are of sufficient depth at their mouths for navigation. For the prevention of smuggling and of the traffic in slaves, the Russians have built a number of forts on the coast. On the Kuban is also a line of forts to keep the tribes in subjection. The passes leading through the

mountains are narrow defiles, which can be traversed only in single file. The villages are generally situated in the valleys which are most difficult of access.—The name Tcherkesses, “cutters of roads,” a term equivalent to cutpurses or highway robbers, was given by the Tartars; the Circassians call themselves Adighei, “the noble.” They are essentially a pastoral as well as a warlike people, averse to labor, and addicted to robbery and bloodshed. They are of middle stature, with broad shoulders, but otherwise slender, having small hands and feet, and keen eyes. Their bearing is courteous and dignified. Their wealth consists in flocks, herds, horses, and arms. Money as a circulating medium is almost unknown. According to their eulogists, the Circassians are the handsomest, bravest, and noblest of mankind; but their detractors represent them as a semi-barbarous horde of marauders. They do not

Circassians.

even constitute one people, but are composed of clans, subdivided into families more or less powerful, under their hereditary heads, who in turn are feudatory to the princes or greater chiefs, also hereditary, but liable to be deposed for misconduct. Circassian pride of birth is excessive, and causes society to be divided into classes as strictly defined as in the most aristocratic countries. With all this they have a theory of republicanism, every free Circassian having a right to make his voice heard in the public assemblies. The social grades are: 1, princes or chiefs, called *pshehs*, *khanuks*, *khans*; 2, nobles; 3, middle class; 4, retainers; 5, serfs, employed either in cultivation of the soil or in menial service. The princes and nobles are the owners of the soil, from whom their tenantry hold the land which they cultivate. The noble lives in his village, surrounded by his people, and exercises a patri-

archal jurisdiction, regulating even their marriages and the education of their children. Having no written laws, the administration of justice was formerly regulated by custom and tradition, and ordinary affairs were administered by a council of the oldest and most respected of the villagers, whose award was final. All ranks associate, and are clothed, fed, and housed alike, the only difference being in their warlike equipment, wherein the rich men display great extravagance; the array of a chief consists of a coat and helmet of mail, sword, javelin, rifle, pistols, poniard, and frequently bow and arrows. The chiefs alone are entitled to the privilege of wearing red. Like most oriental nations, they shave the head, and never remove the head covering. The ordinary costume consists of a tunic descending to the knee, secured around the waist by a leather belt, and having on both sides of the breast from 12 to 20 small pockets in which cartridges are carried, a round fur cap, and cloth trousers of eastern pattern. On a journey a goat's-hair cloak with a hood is added. Their habitations are log huts, put together slightly, so as to be abandoned at short notice. Around these cabins they cultivate millet, barley, and vegetables for their own food, permitting their flocks to pasture among the hills. The Circassian national dish is millet porridge; they also distil a kind of whiskey from millet. Bees are reared on most farms, and mead is a favorite beverage. Great attention is paid to the breeding of horses. Oxen are employed in agriculture. Mules and asses are the beasts of burden, the horse being considered too noble an animal for labor. There is no regular taxation, the lower orders being required to supply what the nobles want; but the vassal who finds the exactions of his lord too severe can transfer his allegiance to another. Some of their domestic customs are curious. A bridegroom makes a show of carrying off his bride by force from her father's house. The Circassian husband has unlimited power over the lives of his wife and children. The wife hides herself from strangers, and the children must stand in his presence. Polygamy is allowed, but custom limits men to one or at most two wives. The women have fine forms and complexion, both of which are carefully preserved by exemption from labor and by attention to diet and cosmetics. The household work is done by the married women. The traffic in their daughters has been the greatest reproach against the Circassians. About 1,000 girls were formerly exported annually. The Russians stopped the trade, but by treaty in 1845 its renewal was permitted. Lady Sheil, in her "Glimpses of Life and Manners in Persia" (London, 1856), gives an interesting account of the slave trade as she saw it in 1849. Dealers from Constantinople and Egypt made voyages to Circassia, taking with them silk and cotton cloths, chintzes, shawls, colored leather, gunpowder, and salt, which they exchanged for females and youths. Ugly and old females were taken for

menial service, and the handsome girls for the harems. Men could not sell their daughters against their consent, but it was the great ambition of a Circassian girl to become an inmate of the harem of a wealthy Turk. Sometimes a man induced his friend to sell him, then took flight, and the amount of the purchase was divided between them. The price of males varied from \$50 to \$400, that of females from \$50 to \$700, according to age and beauty. The traffic was again suppressed in 1855 by the firman of Abdul-Medjid, which prohibited the sale of white persons as slaves. Notwithstanding the prohibition, however, there was in 1856 an absolute glut in the Circassian slave market at Constantinople, and a Circassian girl, formerly thought very cheap at \$500, might then have been had for \$25. The Circassians are fond of music; their instruments are chiefly a shepherd's flute and one resembling a violin, with but two strings. There are wandering poets, and every chief has his own bard. The sexes do not dance together; the young men form a circle, into which one steps and goes through a round of comic leaps and gestures, the others keeping time by clapping their hands. The dance of the girls is similar, but performed with more grace. The Circassians unite into brotherhoods, consisting of 20 or more families, who bind themselves to assist each other in cases of need, and a widow of one is provided for by the whole brotherhood. The religion is a mixture of Mohammedanism, Christianity, and paganism. Nominally they follow the precepts of the Koran, but pay a superstitious reverence to the sign of the cross, while the bulk of the people believe in a good spirit called Merem, and an evil, Tchible, the god of thunder; also Tleps, the god of fire, and Sesserer, of water and winds, and protector of cattle. They have no mosque, but there are sacred groves and mountains where they resort for prayer. Their mollahs or priests are much revered.—The different tribes have a striking similarity in habits and customs, but differ widely in language. Within a narrow space it is said that no fewer than 72 dialects have been counted, and one particular region was named by Abulfeda *Jebel el-Utsun*, the mountain of languages. The language is harsh, abounding in gutturals, and bears little resemblance to any other, except that there are a few words resembling those of the Finnish. Nouns have seven cases, but no gender; the plural is formed by the addition of *khe* or *her*. An *r* affixed to a word serves as an article. The comparative is formed by *nakhai* placed before the adjective, and the superlative by the affix *ded*, or the prefixes *kodo*, *bo*, *bodedo*. The numerals are: *tze*, 1; *tuu*, 2; *sshe*, 3; *pléa*, 4; *tfö*, 5; *kkkhö*, 6; *ble*, 7; *iyé*, 8; *vgu*, 9; *pse*, 10. The personal pronouns are: *serö*, I; *vuore*, thou; *vé*, *ar*, he; *teré*, we; *suoré*, you; *a*, *arikh*, they. Five conjugations have been distinguished in the verb, and the different tenses and moods are expressed by the ter-

minations, as *sé slauguo*, I see; *s'slaugue*, I saw; *s'slauguaga*, I have seen; *s'slauguno sé shite*, I shall see; *slauguner*, to see.—The early history of Circassia is little known, especially that of the eastern part. The people appear in history under different names, as the Zyges of Strabo, the Zuchi of Adrian, the Cercetæ of Pliny, and the Siraks in the middle ages. Conquered by Mithridates, the country passed on his overthrow into the hands of the Romans, under the name of Zichia; but the sovereignty of the emperors was merely nominal. In the 5th century it was subjugated by the Huns, and later by the Khazars. In the 9th century the Circassians made a fruitless effort to regain their independence; after which they separated into two bands, one going to the south of the Caucasus, near Persia, then occupied by the Arabs; the other to the lower Don, whence they subsequently returned. After the overthrow of the empire of the Khazars, Circassia became subject first to the Seljuks, and then to Georgia, whose queen, Tamar, is said to have introduced Christianity. In the early part of the 13th century it was conquered by the Mongols under Batu Khan; and at the end of the 14th it was devastated by Tamerlane, who compelled the people to embrace Islamism. In the 16th century the khans of the Crimea, as successors of the Mongol emperors, claimed the sovereignty over Circassia; but in 1560 the czar Ivan Vasilevitch, who had married the daughter of a Circassian prince, sent an army to the assistance of his father-in-law. After Ivan's death the Circassians submitted to the khans of the Crimea; but in consequence of the exactions and outrages of the Tartar officials, they revolted about 1705, massacred the tax collectors, defeated a Tartar army sent against them, and made an alliance with the Turkish sultan. By the peace of Belgrade (1739) the Circassians were declared independent. In 1781 Russia acquired the Kuban border, and in 1784 the Turks built the fortress of Anapa, and thence stirred up the Circassians against Russia. Anapa was captured by the Russians in 1807, but was restored to the Turks at the peace of Bucharest in 1812. The Turks availed themselves of the quiet which followed to convert the Circassians to Islamism. In 1829 Anapa again fell into the hands of Russia, which by the treaty of Adrianople, of the same year, also acquired all the Turkish possessions on the coast. The Circassians refused to recognize the cession of their country by the Turks, and began the obstinate struggle for independence which made their name famous, and in which they were joined by the Lesghians, Tchetchentches, and others, succumbing, however, in the end. In 1856 a Circassian deputation was sent to Constantinople to implore Turkish protection. In 1862 a deputation arrived at London, and presented to the queen a memorial protesting against the action of Russia and the authority of Turkey to cede their country. During a visit of the

emperor Alexander II. to the Caucasus in 1863, he was waited upon by a delegation of Circassians, who asked to be left in possession of their territory, promising to live on terms of peace and amity with the Russians. The emperor refused to accede to their request, and offered them the alternative between emigration beyond the Kuban and a continuation of hostilities. They chose the latter; but being unable to resist the superior strength and discipline of the Russians, in the following year there was a great emigration of about 200,000 persons into Turkey. The Russian government sent vessels to transport them, and furnished them with provisions as long as they were on the Russian shore. (See CAUCASUS.)

CIRCE, in Greek mythology, a sorceress, daughter of Helios and Perse, and married to a prince of Colchis, whom she murdered. Expelled by his subjects, she was transported by her father to the island of *Ææa*, off the coast of Italy, where she was sojourning when Ulysses touched there. While the hero continued in his ship, he sent some of his followers to pay their respects to the sovereign of *Ææa*, and to solicit refreshments for himself and his crew. Circe received them with apparent hospitality, causing food and wine to be set before them. All ate and drank freely save Eurylochus, and all save he were presently metamorphosed into swine. Eurylochus returned to the ship, and reported to Ulysses what had befallen his companions. Ulysses, who had been rendered proof against enchantment by an herb which he had received from Mercury, hastened to the palace of Circe sword in hand, and compelled the sorceress to restore his followers to their former state. She fell in love with Ulysses, who lived one whole year with her, and she bore him two sons. Before Ulysses left her, Circe recommended him to descend into Hades and consult Tiresias, the seer, in regard to the future. Upon his return from his visit to Tiresias, Circe received him and his followers kindly, explained to them how to avoid the dangers that were before them, and then dismissed them.

CIRCEII, an ancient city of Latium, situated at the N. foot of Mons Circeius (now the mountain promontory Circello), near the sea, 55 m. S. E. of Rome. It was colonized by the Romans in the reign of Tarquin the Proud, who deemed its situation advantageous for commerce, and also wished to make it a bulwark against the Volscians. It is mentioned among the conquests of Coriolanus, and soon after fell into the hands of the Volscians, but was reconquered by the Romans. Circeii subsequently revolted from Rome, joined the Volscians, succeeded in establishing its independence, appeared as one of the cities of the Latin league at the outbreak of the great Latin war in 340 B. C., and furnished one of the two prætors who commanded the whole nation. It appears again among the 30 Latin colonies in the second Punic war, but from

this time seems to have declined, and to have become gradually insignificant. It was subsequently, under the later republic and the empire, a favorite place of retirement for wealthy Romans, having a peculiar attraction in the abundance and excellence of its oysters. It was sometimes selected as a place of exile, and the triumvir Lepidus was banished hither. Its ruins are still to be seen on the Monte della Cittadella, about 2 m. from the sea. The remains of its walls, constructed of polygonal blocks, show a massive style of architecture.

CIRCENSIAN GAMES, the various combats and contests exhibited in the Roman circus, said to have been first instituted by Romulus for the purpose of attracting the Sabines to his new town. A part of them were abolished by Constantine, others by the Goths; but the chariot races continued at Constantinople till the siege of that city by the Venetians in 1204.

CIRCLE, a plane figure bounded by a line every part of which is equally distant from its centre. This line is called the circumference, and in popular language the word circle is sometimes used for circumference. The diameter of a circle is a straight line which passes through its centre and is terminated at both ends by the circumference. The ratio of the diameter to the circumference was shown by Archimedes to be about as 7 to 22, and by Metius as still more nearly 113 to 355, which, though slightly too small, is as accurate as is needed for practical use. The exact ratio cannot be expressed in numbers, although many algebraic expressions can be obtained for it, of which we will give but one. If the number 4 be divided by 1, 5, 9, 13, and every 4th number in succession, and afterward by 3, 7, 11, and every 4th number in succession, the difference between the sum of the first set of quotients and that of the second set will be equal to this ratio; or approximately in decimals, 3·14159265. The ratio of 7 to 22, decimally expressed, is 3·14285714; that of 113 to 355 is 3·14159292.

CIRCLEVILLE, a city, capital of Pickaway co., Ohio, on the left bank of the Scioto river, and on the Ohio canal, which here crosses the river by a handsome aqueduct, 25 m. S. of Columbus; pop. in 1870, 5,407. It occupies the site of an aboriginal fortification of circular form, from which its name is derived. The surrounding country is rich and highly cultivated. The Cincinnati and Muskingum Valley railroad passes through it. It contains numerous mills and factories, and three weekly newspapers. There are 18 schools, of which 2 are high schools, 19 teachers, and 728 male and 688 female pupils in attendance.

CIRCUITS (Lat. *circuitus*, from *circumire*, to go around), the periodical progress of the several judges of the superior courts of the common law in England and Wales through the several counties for the purpose of administering justice. The term is also applied to the several divisions of the kingdom which are made for

the purposes of these visits, and through each of which one of the judges will go in order to hold courts twice or more each year in every county. The United States is also divided into circuits similarly, and the justices of the supreme court and circuit judges go upon the circuits periodically in like manner. There are like divisions of the several states for judicial purposes, and in some these are called circuits, in others not. (See COURT.)

CIRCULAR MEASURE, a measure of angles produced by dividing the circumference of a circle, with its centre at the vertex of the angle, into 360 equal parts called degrees. Each degree is also divided into 60 minutes, and each minute into 60 seconds. Circular minutes and seconds are marked by accents (' and ''), while measures of time of the same name are marked *m.* and *s.*

CIRCULATING MEDIUM. See MONEY.

CIRCULATION. Under this title we shall examine only the circulation of blood in the animal economy, omitting all that relates to the circulation of lymph and chyle, and to the circulation of the nutritive fluids in plants. Before stating by what decisive experiments and reasonings the eminent William Harvey (1619, 1628) proved the circulation of the blood, we must remind the reader of some points in the anatomy of man and of the higher animals which are essential to the understanding of our subject. The heart, which is at least one of the principal organs that circulate the blood, is a complicated muscular apparatus, composed of walls separating four cavities, two on the left and two on the right of the organ. Although there is only a muscular wall between these two sets of cavities, and although they belong to one single organ or apparatus, the two sides of the heart, in which are these two sets of cavities, are sometimes called, for the sake of brevity, the right heart and the left heart. Of the four cavities of the heart and of their walls, two, the upper ones, are called the auricles, while the two lower ones are called the ventricles; so that there is a left auricle and a left ventricle, constituting the left heart, and a right auricle and a right ventricle, constituting the right heart. The circulation of the blood takes place in the following way: From all the parts of the body black blood, called also venous blood because it comes by the veins, reaches the right auricle, which propels it into the right ventricle, from which it is sent to the organs of respiration, *i. e.*, the lungs. The blood vessel that brings the blood from the right ventricle into the lungs is the pulmonary artery. The lungs send back this blood to the heart through blood vessels which, on account of their structural resemblance to veins, although they do not carry black or venous blood, are called pulmonary veins. In the lungs the blood by the influence of respiration becomes red, and in consequence the heart receives red blood from the pulmonary veins. The left auricle is the place of reception for

this blood, which is thence carried into the left ventricle. By a large blood vessel called the aorta the blood expelled from the left ventricle passes into the arterial system, and is thence distributed to all the parts of the body. So that, as may be now easily understood, there is apparently a double circulation, one through the whole body, and one through the lungs and the heart. The blood from all parts of the body comes to the heart through the veins; it passes from the trunks of these vessels, the *venæ cavæ*, into the right auricle, thence into the right ventricle, which sends it to the lungs through the pulmonary artery; thence it returns to the heart by the pulmonary veins, and enters the left auricle, which impels it into the left ventricle, from which it goes to the whole body through the aorta and its ramifications, the various arteries; finally, from the arteries it passes into the veins through the very minute blood vessels called capillaries. In writing the names of the parts through which the blood circulates, we may begin with either, as these parts form a circuit; thus:

	10. General capillaries.	
1. Veins.	9. Aorta and arteries.	
Right heart. } 2. Right auricle.	8. Left ventricle.	} Left heart.
3. Right ventricle.	7. Left auricle.	} heart.
4. Pulmonary artery.	6. Pulmonary veins.	
	5. Capillaries of the lungs.	

If, instead of beginning with number 1, we begin with number 7, the blood then passes from 7 to 8, to 9, to 10, to 1, to 2, to 3, to 4, to 5, to 6, and thence reaches again number 7. The principal facts discovered or clearly proved for the first time by Harvey are: 1, that the movements of the heart are similar to those of the muscles of the limbs, &c., as regards the parts which produce them; 2, that the arteries become full at the time the ventricles of the heart expel the blood they contain; 3, that the pulmonary artery receives blood at the same time the aorta and other arteries receive it, and therefore that the two ventricles contract and expel the blood at the same time; 4, that the two auricles contract simultaneously, and that their contraction precedes that of the two ventricles; 5, that after a ligature has been applied on an artery this vessel becomes quite distended with blood between the ligature and the heart, and empty in the other parts, showing that the blood comes from the heart into the arteries; 6, that after the application of a ligature on a vein the blood disappears above the ligature, *i. e.*, in the direction toward the heart, while it accumulates in the vein below the ligature, *i. e.*, in the part which seems to be separated from the heart; 7, that the valves in the veins prevent the blood from going in a wrong direction. From these facts and the natural conclusions that may be drawn from them, and also from many other facts and reasonings, Harvey deduced the theory of the circulation of the blood, which we have stated, and which is now universally admitted. Harvey, in giving

VOL. IV.—39

this complete demonstration of the circulation of the blood, achieved the most important discovery yet made in physiology.—We pass now to the examination of the most interesting questions concerning the circulation of the blood, omitting all those relating to the frequency, strength, and causes of the movements of the heart, for which see HEART and PULSE. There are four principal members or parts of the circulatory apparatus, each of which has a special office to perform in the function as a whole. These are: 1, the heart; 2, the arteries; 3, the capillaries; and 4, the veins. We shall describe the action of these different organs or groups of organs in succession.—The heart is the main cause of the movement of the blood in the circulation. It is, as Harvey first demonstrated, a muscular organ, which contracts upon the blood contained in its cavities and drives it out into the arterial trunks, exactly like an animated force pump. The left ventricle, which is by far the thickest and strongest of all the chambers of the heart, nearly empties itself at each contraction, and the blood, being prevented from regurgitating into the auricle by the shutting back of the ventricular valves, is forced onward by a vigorous impulse into the aorta. The elastic resistance of the arterial system, being inferior in force to the muscular contraction of the heart, yields before it, and the blood which previously filled the left ventricle is thus suddenly transferred to the cavity of the aorta. The contraction of the heart is then at once followed by a condition of relaxation, and the ventricle begins to be again passively filled by the blood flowing into it from behind, from the veins and through the auricle. Thus the circulation through the heart is intermittent. The blood is at one instant driven out of the ventricle in a powerful stream, and is then temporarily arrested until another muscular contraction takes place, to repeat the same phenomenon.—*Movement of the blood in the arteries.* The most marked physical property of the arteries, as a whole, is their elasticity. In this respect they are like a series of India-rubber tubes, owing to the abundant development of elastic fibres in their middle coat. Accordingly they are distensible, but offer nevertheless a certain amount of resistance to any distending force. This resistance, as we have remarked above, being less than the impulse with which the blood is injected into them from the heart, the arteries expand at the instant of the heart's contraction, and are thus made to contain a larger quantity of blood than before. This expansion of the arteries under the heart's action, which is nearly simultaneous all over the body, can easily be perceived by the finger placed above an artery of moderate size, and is known as the arterial pulse. As each stroke of the pulse is caused by and is synchronous with a cardiac pulsation, its frequency becomes a valuable and convenient means by which the

physician estimates the rapidity of the heart's action. As soon, however, as the cardiac contraction which caused the dilatation of the arteries comes to an end and is followed by relaxation, then the elastic reaction of the arteries themselves, compressing the blood, drives it onward toward their terminal ramifications and into the capillary system. Under these circumstances the blood would be partly forced backward into the relaxed ventricle, were it not for three thin but strong membranous valves which guard the orifice of the aorta at its junction with the heart, and which shut backward at the instant of the heart's relaxation, and thus prevent any backward regurgitation. Thus the blood, forced into the arteries by the muscular power of the heart, is driven onward to the capillaries by the elastic force of the arteries themselves. Nevertheless the heart is the essential cause even of the arterial circulation; for the elasticity of the arteries, which is a passive physical property, like that of India rubber, is called into exercise only by the distention of these vessels under the cardiac impulse; and the blood would soon cease flowing were it not, at each successive contraction of the ventricles, thrown into the arterial system in superabundant quantity. The arterial circulation, carried on under the combined influence of the two forces just described, presents certain peculiarities which are worthy of notice. First, its rapidity varies at different periods during a single pulsation. At the instant of the heart's contraction the blood moves with a maximum velocity; in the intervals of the heart's action, when it is compressed by the arterial elasticity alone, its velocity is diminished. Consequently, if an artery of medium size be wounded, the blood escapes from it in jets. At each cardiac pulsation the stream of blood rises and flows more rapidly; at each relaxation it falls to a lower level and runs more slowly. The stream is never entirely interrupted. On the contrary, it flows always with a considerable degree of force; but its increased velocity at each period of the heart's action is abundantly visible. It is this pulsatile character of the hæmorrhage from arteries, as well as the florid color of the arterial blood, which enables us at once to distinguish it from hæmorrhage which takes place from veins or capillaries. Chauveau has succeeded in measuring these variations of rapidity in the arterial circulation, by an ingenious instrument adapted to the carotid artery of the horse. He finds that at the instant of the heart's contraction the blood is suddenly put in motion with a comparatively high degree of rapidity, amounting on the average to 20 inches per second; the movement of the blood is then diminished or brought to a standstill immediately before the closure of the aortic valves; on the closure of the valves the blood again moves forward with a velocity of about $8\frac{1}{2}$ inches per second; and it then diminishes gradually, falling to a

little less than 6 inches per second by the end of the period of relaxation. Secondly, the difference between the two conditions of distention and collapse of the artery diminishes from the heart outward; for at a distance from the heart the force of the cardiac pulsation has been partly expended in distending the larger vessels in its neighborhood, and consequently the distention of the remote artery is less; and at the time of cardiac relaxation the smaller artery is still kept partly distended by the elastic reaction of the larger ones behind. Thus, as in the case of water driven by the strokes of a force pump through an elastic air chamber, the intermittent action of the heart upon the blood becomes more and more equalized, from the centre of the circulation outward; and in the smallest arterial ramifications the pulsating character of the flow is hardly visible to the naked eye, though still perceptible under the microscope. The pressure exerted upon the blood in the arterial system may be measured by attaching the carotid artery of the living animal to a reservoir of mercury provided with an upright open tube or pressure gauge. When the cavity of the artery is allowed to communicate freely with the interior of the reservoir, the mercury, under the pressure of the blood, rises in the upright tube, and the height of the mercurial column thus becomes an indication of the pressure to which the blood itself is subjected within the artery. The arterial pressure, measured by this test, is found to equal on the average a column of mercury 150 millimetres (6 inches) in height. Various oscillations of the level of the mercury show the variations in pressure upon the blood during the different periods of a pulsation; but in the healthy condition it seldom or never falls below 130 millimetres.—*Movement of the blood in the capillaries.* In the capillary vessels the movement of the blood at once loses all trace of the pulsating character which it presented in the arteries, and becomes perfectly steady and uniform. This is because, on leaving the arteries and passing into the minute and excessively abundant capillary vessels, the same quantity of blood at once becomes subjected to the influence of a much greater extent of elastic surface; for the walls of the capillaries are themselves elastic, and the substance of the organs in which they ramify has also to a greater or less degree the same property. The effect of this increased elasticity of the surrounding parts upon a given quantity of blood is to equalize its rate of movement, and convert it into that of a completely uniform current. Nevertheless, the physical cause of the passage of the blood through the capillary vessels is simply the pressure from behind to which it is subjected in the arterial system. This is fully evident from the following considerations: If the nozzle of an injection pipe be placed in the femoral artery of a recently killed animal, and liquid blood be forced by it through the terminal ramifications of the artery and the capillary

vessels of the limb, so as to return in a full stream by the femoral vein, it is found that the force requisite to accomplish this result, as measured by a pressure gauge connected with the syringe, is from 120 to 130 millimetres of mercury. Prof. Sharpey of London found that an injection might be made to pass in this way from the mesenteric artery through both the two successive capillary systems of the intestine and the liver, and return in a full stream by the vena cava, under the pressure of a column of mercury 130 millimetres in height. But we have already shown that the blood is habitually subjected in the arteries of the living animal to an average pressure of 150 millimetres. This force accordingly is amply sufficient to account for the movement of the blood through the capillaries generally, from the arteries to the veins. The rapidity of movement of the blood in the capillaries is much less than in the arteries. This is due to the fact that the extent of vascular surface with which the blood comes in contact on entering the capillary system is vastly increased owing to the small size and great number of the vascular canals through which it now flows; and consequently the mechanical resistance to its passage is increased in corresponding ratio. It is estimated, from data derived from microscopic inspection of the capillary circulation in transparent tissues, that the rate of movement of the blood in these vessels is about $\frac{1}{3}$ of an inch per second. It must be remembered, however, that while the capillary vessels are excessively numerous, and their united calibre therefore very large, their length, on the other hand, is very small. The effect of this anatomical arrangement accordingly is to disseminate a comparatively small quantity of blood, while it is contained in the capillary vessels, over a very large space; so that the physiological and chemical reactions taking place between the blood and the substance of the tissues are accomplished almost instantaneously. Furthermore, although the rate of movement of the blood in these vessels is very slow, yet as the distance to be passed over between the arteries and the veins is very small, the blood requires but a few seconds to traverse the capillary system, and to commence its returning passage by the veins.—*Movement of the blood in the veins.* In the veins the blood is gradually collected from the peripheral parts of the circulatory system and returned to the right side of the heart. Beginning by small rootlets directly connected with the capillaries, the veins constantly unite with each other into larger branches and trunks, converging in this way toward the centre of the circulation, until they terminate in the right auricle of the heart by two great canals, one coming from the upper and one from the lower parts of the body, and named accordingly the *vena cava superior* and the *vena cava inferior*. The walls of the veins are thinner than those of the arteries, and are less distensible and less

elastic; but they have great strength owing to the large proportion of white fibrous tissue in their structure, and are able to resist without laceration an equal or even greater pressure than the arteries of corresponding size. They are provided at various intervals with membranous semi-lunar valves, which open toward the heart and shut backward in the opposite direction. The main cause of the movement of the blood in the veins is the pressure from behind exerted by the blood as it is carried through the capillary circulation. It thus fills the rootlets and smaller branches of the veins with a constantly increasing supply, and urges the blood which they already contained onward to the heart. If this were the only force at work, the venous system would after a time become so filled with blood that its resistance would counterbalance the pressure of blood from the arteries, and the circulation would come to an end by simple engorgement of the veins. But in point of fact the right ventricle of the heart at each pulsation discharges into the pulmonary artery, and, as it were, lifts away from the venous system a portion of the blood which had accumulated in it. Thus the veins are protected from engorgement, and their backward resistance is kept always inferior to the pressure by which the blood enters them from the capillaries. The venous circulation is also much facilitated by the alternate contraction and relaxation of the voluntary muscles. When any one of these muscles contracts, it increases in thickness exactly in proportion as it diminishes in length. The effect of this lateral swelling of the muscles in activity is to compress the veins situated between them, and the blood is thus forced out of the compressed portion. The valves of the veins, already mentioned, prevent the blood from regurgitating toward the extremities, and it is consequently driven onward toward the heart, in which direction alone the passage for it is clear. When the muscles relax, the corresponding portion of the vein is again rapidly filled with blood coming from the extremities, and the circulation goes on with increased facility from the circumference toward the centre.—*Variations of the circulation in different parts.* We know that the capillary circulation in various parts of the body is subject to marked variations, dependent on external or internal causes. Thus a mustard poultice, or a sponge moistened with water of ammonia, applied to the skin, will cause a local and circumscribed redness, due to an increased capillary circulation in the part. The face will become flushed or pallid under the influence of mental emotion, and cold or hot applications will cause a similar change of color in those parts of the skin with which they are brought in contact. Even the internal organs exhibit fluctuations of the circulation of the same kind, to a marked degree. When a glandular organ is about to enter into active secretion, it is the seat of a kind of

physiological congestion. Its capillary blood vessels enlarge in diameter, and admit a greater quantity of blood than before. The rapidity of the capillary circulation is at the same time increased, so that a larger quantity of blood than usual passes in a given time through the vessels of the part. When the period of functional activity comes to an end, the capillary vessels return to their original diameter, admit a smaller quantity of blood, and the color of the organ resumes its ordinary pallid state. These variations in the capillary circulation are due to the action of the smaller arteries. The arteries generally, as we have already shown, are characterized mainly by their passive physical property of elasticity. But the medium-sized and especially the smaller arteries are provided also with minute muscular fibres, running round them in a circular or transverse direction, and forming part of their middle coats. By the greater or less degree of contraction of these muscular fibres, the calibre of the arterial twig is enlarged or diminished, and consequently the quantity of blood admitted by it to the capillary vessels varies in a corresponding degree. Thus, although the circulation everywhere is kept up by the central force of the heart's action, yet its influence on particular parts is modified in degree by the contracted or relaxed condition of the smaller arteries.—*General rapidity of the circulation.* The time required for the blood to traverse the entire round of the double circulation, that is, through the lungs and the general capillary system, returning again to the right side of the heart, has been found by experiment to be very much shorter than was formerly supposed. The observations of Hering, Poisseuille, Blake, and Matteucci on this subject were made, for the most part, by injecting into the jugular vein of one side upon the living animal some substance, like ferrocyanide of potassium, which could readily be recognized by its chemical reactions. Blood was at the same time drawn from the jugular vein of the opposite side; and the interval which elapsed before the appearance of the foreign salt in the blood drawn from this second opening indicated the time required for the blood to pass from the point of injection through the vena cava to the heart, from the right side of the heart through the lungs to the left cavities, from the left ventricle through the carotid arteries and the capillary vessels of the head, and thence downward to the jugular vein on the opposite side. The average results obtained from these experiments were as follows:

TIME REQUISITE FOR THE COMPLETE CIRCULATION OF THE BLOOD.

In the horse.....	28 seconds.
“ dog.....	15 “
“ goat.....	13 “
“ fox.....	12½ “
“ rabbit.....	7 “

In man the complete double circulation probably requires from 15 to 25 seconds.

CIRCUMCELLIONES, fanatics who, about the year 317, in the war of the Donatists in Africa, occasioned by the election of the Carthaginian bishop Cæcilianus, espoused the cause of the Numidians or Donatists, and went about as marauders to intimidate the Carthaginian party, and to commit excesses in which the Donatists rejoiced, but for which they were unwilling to be responsible. They had a strong desire for the honor of martyrdom, and sought it at the hands of the dominant party by violence upon the prevalent social institutions and the civil rights of the citizens. Thus they threw themselves between the debtor and creditor, and demanded the discharge of the claim by the creditor on pain of death. Whenever they met a master and a slave, they manumitted the slave, and compelled the master to take his place. Constantine treated these excesses with forbearance; but Constans, his successor, deprived the Donatists of their churches, and attempted to bring them to peace. This kindled the fanaticism of the Circumcelliones anew. Headed by Fasir and Axid, they committed new depredations, styling themselves Agonistici, and their leaders, “leaders of the sons of the Holy One.” Their frenzy increased so furiously that they committed suicide in great numbers, and the Donatist bishops were obliged to apply to the civil power to restrain them.

CIRCUMCISION (Lat. *circumcisio*, a cutting around), a practice of eastern nations, consisting in cutting off the prepuce or foreskin in males and the internal labia in females. Among the Jews it is a strictly religious rite, and is used only on males. In ancient times it was not only obligatory on all males born of Jewish parents, but also on all proselytes, and on all the slaves of Jewish masters. The rite originated, according to the book of Genesis, in the command of God to Abraham, and was nationalized by Moses. It was thenceforth practised by the Jews, except during the journey through the wilderness. Circumcision among the Jews is performed on the eighth day after birth. From the fact that this rite was required by religious ordinance, the term “uncircumcised” became a term of national reproach, and is analogous to the word “heathen” as used by Christian writers. The Egyptians, according to Herodotus, practised circumcision. It is certain that at a later period in Egyptian history, under Persian and Greek influence, circumcision was confined to the priests and sages, but Herodotus makes no limitation in his statement. On the other hand, he states that the tonsure was confined to the priests. He also says that the Colchians (an Egyptian colony, as he believed) practised circumcision. The same authority tells us that the Ethiopians practised it; and to this day the Coptic and Abyssinian Christian churches observe the custom. The Abyssinian church imposes the rite on both sexes. The Epistle of Barnabas testifies to the fact of Egyptian circumcision, and declares also that the cere-

mony was observed by the Arabians and Syrians. Jerome says that in his day the majority of Egyptians, Idumæans, Ammonites, Moabites, and Ishmaelites were circumcised. The Mohammedans also practise it; and although the Koran does not enjoin it, it has extended itself wherever the Mohammedan religion has been adopted. In Arabia the rite is performed on both sexes. The Arabians have a tradition that Mohammed said that circumcision was honorable in women. Pythagoras is said to have submitted to circumcision in order to obtain instruction from the Egyptian priests in their sacred doctrines. A portion of the Phœnician nations practised the rite, but the Philistines did not. The aboriginal Mexicans were found to observe this custom. The Friendly Islanders, the inhabitants of the Indian archipelago, those on the west coast of Africa, those of Madagascar and the Philippine islands, and even the Hottentots, have a custom regarded as a remnant of the same observance.

CIRCUMNAVIGATION. Any voyage around the world is properly so called; but as modern commerce encircles every sea, the term is confined to continuous voyages around the globe for some specific purpose, as for survey, discovery, or other scientific object. The following list comprises the principal circumnavigators, with the date of the commencement of each voyage: Magalhaens, 1519; Mendana, 1567; Drake, 1577; Cavendish, 1586 and 1591; Queiros, 1605; Le Maire, 1615; Tasman, 1642; Dampier, 1679; Roger and Cooke, 1708; Roggeween, 1721; Anson, 1740; Byron, 1764; Wallis and Carteret, 1766; Bougainville, 1766; James Cook, 1768, 1772, and 1776; Krusenstern, 1803; Kotzebue, 1823; King and Fitzroy, 1826; Belcher, 1836; Dumont d'Urville, 1837; Wilkes, 1838. Travellers and tourists at the present day very frequently make entire circumnavigations of the globe, starting from any point in Europe or America, and availing themselves of the various established lines of communication.

CIRCUS, in ancient Rome, a place reserved for public games, races, and shows of different kinds. The *circus maximus*, in the valley now called Via de' Cerchi, was founded by Tarquin the Elder. It gradually became one of the most magnificent structures of Rome. The original temporary platforms erected at private expense, by patricians and equites, who alone witnessed the shows, were replaced by three galleries or tiers of seats, running in an elliptical form around the arena. Iron railings 12 to 14 ft. high, and a ditch 10 ft. broad and 10 ft. deep, a work of Cæsar, separated the seats from and defended them against the furious beasts of the arena. Through its middle length ran a low wall called *spina*, at each end of which were erected three wooden (afterward gilt) cylinders of conical shape, forming the goals of races. The *spina* was adorned with gilt statues, images of deities, reliefs, altars, and chapels, and at its middle with an obelisk 132 ft. high,

brought by Augustus from Egypt. There were also two platforms, on one of which reposed the images of seven dolphins, on the other the seven *ova*, imitations of eggs, which marked the numbers of the rounds done by the racers, one of the eggs being taken off after each. At one of the narrow sides of the circus the galleries were wanting, and replaced by the stores for chariots and horses. The length of the circus was in the time of Julius Cæsar more than 3 stadia, its breadth 400 ft., its circumference 8 stadia. Destroyed by fire under Nero, and rebuilt by Trajan, it was made by this emperor capable of containing 500,000 spectators, and completed under Constantine, who adorned it with another obelisk. The circus Flaminius or Apollinaris, erected probably by Caius Flaminius, in the Prata Flaminia, out of the city, and which in a show under Augustus was filled with water and became the scene where 36 crocodiles were killed; the circus of Sallust, near his gardens, destined for shows of sea fights; the Vaticanus, commenced by Caligula, completed by Nero; the Agonalis, erected by Alexander Severus; those of Flora and Hadrian; and the circus maximus, were all destroyed. A circus attributed by antiquaries to Caracalla, near the Appian way, about two miles from the city, is the only one that remains in good preservation at Rome. More or less remarkable ruins of similar structures, erected in the ancient provinces of the Roman empire, are still visible in Alexandria, Rhodes, Athens, Gaza, Jerusalem, Nîmes, Narbonne, &c.—In modern times the name is applied to a building or enclosure within which is contained a circular space designed for the exhibition of feats of horsemanship. The most celebrated amphitheatre in London used for this purpose is Astley's. The present edifice is the fourth which has been erected upon the same spot, the three previous ones having been destroyed by fire. In Paris and Madrid there are several circuses, the finest of which in the latter city, the *Circo de Prie*, is one of the largest and handsomest amphitheatres in Europe. In the United States equestrian performances are exhibited by companies which travel through the country during the summer months. The exhibitions are given in large tents. The wagons used for the transportation of these tents and the performers, with the exhibition horses, form a large train, and enter the towns and villages on their route in grand procession. The capital invested in each enterprise of this kind is very great, and the number of companies engaged in the business is considerable.

CIRENCESTER (colloquially called *CICETER*), a market town and parliamentary borough of Gloucestershire, England, on the river Churn, and on the Cheltenham branch of the Great Western railway, 15 m. E. S. E. of Gloucester, and 95 m. by rail N. W. of London; pop. in 1871, 7,681. It is one of the greatest marts in England for wool. It has a fine old church,

which has been restored at a cost of £12,000, and a free grammar school founded under Henry VII. Near the town is a noted agricultural college. It occupies the site of a Roman station called by Ptolemy Corinium, by Richard of Cirencester Corinum, and by Antoninus Durocornovium.

CIRILLO, Domenico, an Italian republican and naturalist, born in 1734, died on the scaffold at Naples in 1799. He officiated in early life as professor of botany, afterward accompanied Lady Walpole to France and England, became a fellow of the royal society of London, a friend of Buffon, D'Alembert, and Diderot, and on his return to Naples was appointed physician of the court. After the proclamation of the republic by the French, he was chosen representative of the Neapolitan people, and member of the legislative commission (1799); and on the reestablishment of royalty he suffered death on the scaffold, rather than take the oath of allegiance or ask a pardon from King Ferdinand. His chief writings are *Fundamenta Botanica* (2 vols. 8vo, 1787), and *Entomologia Neapolitanæ Specimen* (folio, 1787).

CIRRIPEDES, or **Cirrhopoda** (Lat. *cirrus*, curly, and *pes*, a foot), a group of articulated animals, long regarded as belonging to the *mollusca*, but

Specimens of the Group of Cirripedes. 1 and 2. Coronula diadema (sessile). 3. Conchoderma aurita (pedunculated).

really to the class of crustaceans, and to the order of entomostracans. The barnacles and acorn shells formerly described among the multivalves are included in this class. Their bodies are soft and protected by the shelly covering secreted from their surface. But the anatomical structure of the cirripedes (of the nervous system particularly) connects them with the articulata, and so also their development from the egg and subsequent transformation. (See BARNACLE.) A peculiar feature is the prolongation of the body and its division into several branches, each of which is furnished with a pair of curled arms filled with cilia or hair-like filaments resembling feathers, and which are constantly moving in the water

for the purpose of collecting food. The class is divided into two principal groups, the pedunculated and the sessile; the former, like *anatifæ*, having a long peduncle, or footstalk, by which the animal fastens itself to rocks or wood; and the latter, like the barnacle, being deficient in this, the shell consequently lying close to the substance to which the animal adheres. Several genera of each group are described, all marine.

CIRTA, the capital of the ancient Massylii, in Numidia, on the site of the modern city of Constantine, Algeria. It was built by architects from Carthage, and its name in Phœnician signified city. It had great natural strength, standing upon a steep rock, almost surrounded by a tributary of the Ampsaga (now the Rumel). The palace of the Massylian kings was one of its ornaments. In the second Punic war it was in league with Carthage during the reign of King Gala; but his son and successor Masinissa joined the Romans in 206 B. C., and contributed to their success, but was himself forced to fly before the Carthaginians and their ally Syphax, until toward the close of the war the Romans restored him. His successor Micipsa enlarged and beautified Cirta, settling Greek colonists in it, and in his time it maintained an army of 10,000 cavalry and 20,000 infantry. After his death, when the Romans divided the kingdom between Adherbal, the legitimate heir, and Jugurtha, the former held the capital. He was besieged there by Jugurtha, and forced to surrender. This act brought on the Jugurthine war, and after the defeat and death of Jugurtha Cirta passed with the rest of Numidia under the Romans, who established there a colony, called Colonia Sittianorum, from the chief Sittius to whom it was granted by Julius Cæsar. It retained this name until the time of Constantine, who restored it from the ruin into which it had fallen, and called it Constantina. It was the central point for all the Roman roads in Numidia. Its ruins are more extended than the modern city. Among them are the bridge across the Rumel, adorned with bass reliefs, and still in good repair, and four gates with Roman sculptures. A triumphal arch has been removed to Paris.

CISALPINE REPUBLIC, a commonwealth founded by Bonaparte in Italy in 1797, consisting of the Cispadane and Transpadane republics, which he had previously established. It embraced Austrian Lombardy, including Mantua, the Venetian districts of Bergamo, Brescia, and Cremona, Verona and Rovigo, the duchy of Modena, the principalities of Massa and Carrara, with the three legations of Bologna, Ferrara, and Ravenna, besides a part of the Grisons. It was divided into ten departments, with Milan as the capital. Austria acknowledged its existence by the treaty of Campo Formio. It followed the destinies of the French in Italy. On their defeat in 1798 the republic was abolished, and reestablished in 1800, after

the victory of Marengo. Austria was again forced to acknowledge this independent state on the conclusion of the peace of Lunéville (1801). Instead of Cisalpine, it was called (1802) the Italian republic, and under the empire it became the kingdom of Italy.

CISLEITHANIA, or **Cisleithan Austria**, a name which since 1867 is frequently (but not officially) applied to that part of the Austro-Hungarian monarchy which is represented in the Reichsrath of Vienna. It embraces the crownlands formerly belonging to the German confederation, Dalmatia, Galicia, and Bukowina. The name is derived from the little river Leitha, which separates Lower Austria from Hungary, and thus forms part of the frontier. It contains a little less than one half the area and about four sevenths of the population of the monarchy.

CISPADANE REPUBLIC, a republican state organized in Italy by Bonaparte after the battle of Lodi, in 1796. It consisted of Modena, Reggio, Ferrara, and Bologna, being separated from the Transpadane republic by the Po (Padus), from which it derived its name. In 1797 the Cispadane was merged in the Cisalpine republic.

CISSEY, Ernest Louis Octave Courtot de, a French soldier, born in Paris in 1812. He belongs to a noble family of Burgundy, and was educated at Saint Cyr and at the school for staff officers. In 1835 he became aide-de-camp of Gen. Trézel, and served with distinction in Algeria till 1852, and in 1854 in the Crimea, reaching the rank of brigadier general after the battle of Inkerman. He was commanding general of the 11th division at Rennes from 1863 till the outbreak of the Franco-German war in 1870, when he led the first division of the fourth corps under Ladmirault in a number of engagements near Metz. He disapproved (Oct. 22) of Bazaine's determination to capitulate, urging in vain a renewed attempt to break through the German lines. Bazaine sent him to the headquarters of the chief of staff of the German army, to arrange the terms of capitulation in such a manner as to include in them only the city and citadel of Metz, and not the French army; but he accomplished nothing, and became for a short time a prisoner of war in Germany. In February, 1871, he was elected to the national assembly for the department of Ile-et-Vilaine, and joining the army at Versailles in March, he operated at the head of the second corps against the commune, entered Paris May 22, and succeeded in gaining control of the entire left bank of the Seine. He was appointed minister of war June 5, and continues (1873) to hold that office.

CISTERCIANS, a widely extended branch of the Benedictine order, founded in the 11th century by St. Robert, a French nobleman by birth, and a Benedictine abbot, who, being very zealous for the strict observance of the Benedictine rule, and unsuccessful in his efforts to enforce it in his abbey, placed himself at the head of some hermits and settled with them at Mo-

lesme. Some difficulties arising in this new community, he left it in company with several others, and made a new settlement at Cîteaux (Lat. *Cistercium*), near Dijon, in the diocese of Châlons-sur-Marne (1098). After enduring great poverty and hardships for some time, the infant community was taken under the protection of Eudes, duke of Burgundy, and the bishop of Châlons; the latter of whom erected it into an abbey, and appointed St. Robert abbot. The latter was recalled after a time to Molesme, and left Cîteaux under the direction of St. Alberic, after whose death, in 1109, St. Stephen Harding, an Englishman, became abbot. The austerities practised in this community were so great that many of the members died, and no person dared to enter the order, which was threatened with extinction. The accession of St. Bernard, with 30 young men, mostly of noble

A Cistercian Monk.

birth, saved it from destruction, and infused into it new life. It soon began to flourish and extend itself, so that in 1151 the number of abbeys had increased to 500, and in 1251 to 1,800. The order became so powerful that several popes were indebted to its recognition and support during the confusion of the 12th century for the maintenance of their authority. Cardinals, archbishops, and bishops often assisted at the general chapter of abbots. Two popes (Eugenius III. and Benedict XII.), 40 cardinals, and a great number of bishops were elected from the order, and several kings and princes assumed its habit. St. Bernard implanted a taste for literature and science in the order in its infancy, and took measures to have every monastery furnished with an excellent library. The especial branch of the Cistercians was music. The golden age of the order continued until the relaxation of discipline, and

the foundation of the Dominicans and Franciscans, caused it to begin to decline. Extraordinary and oft-repeated efforts were made to bring it back to its pristine state, but they proved only partially successful. The spirit of reform produced several new congregations under the Cistercian rule, the principal of which are the Bernardines and Feuillants. The number of convents of the Cistercian order at present existing is small. There are some in Austria, Switzerland, Poland, and Belgium. There is also one in Leicestershire, England, called Mt. St. Bernard. In Italy they have been suppressed, with the exception of one house in Rome. An order of Cistercian nuns was founded in 1120 by Abbot Stephen of Cîteaux. They were at first subject to the authority of the abbot general, subsequently to that of the diocesan bishops. They increased so rapidly that at one time they had 6,000 convents. In Germany some of the abbesses had till 1803 the dignity of princesses of the empire. The most celebrated convent of the order was that of Port Royal in France. At present (1873) only a few convents are left in Switzerland, Germany, and France.

CÎTEAUX, a hamlet of France, in the department of Côte d'Or, on the Vouge, 14 m. N. E. of Beaune, once celebrated on account of its abbey, the chief house of the Cistercian order. The abbey buildings, a great part of which still exist, were magnificent. They have been converted into a reformatory, religious, and industrial penitentiary for juvenile offenders, which is under the care of priests, sisters of charity, and lay brothers. An agricultural college is connected with it, and the institution produces excellent butter and other articles of trade, and is nearly self-supporting. The surrounding country, mostly belonging to the convent, was greatly indebted to the management of the abbots for the superiority of its wines. The vineyard in which the celebrated Clos-Vougeot is raised was formerly part of the property belonging to the abbey.

CITHÆRON (now *Elatia*), a range of mountains in Greece, separating Bœotia from Megaris and Attica. It is said to have derived its name from an early king of Platea, who was an adviser of Jupiter in one of his angry dissensions with Juno. Hence the summit was sacred to Jupiter, and the festival of the Dædala, in honor of his reconciliation with his spouse, was celebrated upon it. Cithæron was also sacred to Bacchus, and the scene of his mystic rites. It was here that Actæon was changed into a stag and chased by his own hounds, that Pentheus was torn to pieces by the Bacchantes upon whose orgies he was stealing a look, and that the infant Œdipus suffered his exposure. Cithæron was covered with a forest which abounded in game. The Cithæronian lion, slain by Alcathous, was famed in mythology.

CITIZEN (Fr. *citoyen*), a member of a free commonwealth. Aristotle defines a citizen to be one who participates in the legislative and

judicial authority of the state. But in every state there are two classes of citizens, those who are permitted to participate in the government, and those who are not. All persons born within the state, irrespective of age, sex, or condition, are presumptively citizens: others may be admitted to citizenship either by special legislative enactment, or by some form of naturalization under general laws. The children of citizens born while their parents are abroad temporarily or on the public service are also citizens. But those only exercise the right of suffrage who in addition to citizenship have such other qualifications as the law may have prescribed. In the United States, by the 14th amendment to the constitution, all persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the state wherein they reside. This amendment put at rest the disputed question whether the freedmen and other blacks were citizens; but it does not embrace Indians who still retain their tribal relations, and who are therefore only in a much qualified sense subject to the jurisdiction of the United States. Sec. 2, art. 4 of the constitution, construed in *Ward v. Maryland*, 12 Wallace, 418, provides that "the citizens of each state shall be entitled to all privileges and immunities of citizens in the several states;" and the 14th amendment prohibits the states from abridging the privileges and immunities of citizens of the United States. This amendment was construed in the New Orleans slaughter house case, decided by the supreme court of the United States in April, 1873, in which it was shown that the privileges and immunities which belong to one as a citizen of a state, and those which pertain to a citizen of the United States, are not the same, and that the latter only are protected by the 14th amendment.—See Story's "Commentary on the Constitution," 4th ed., chap. 47, and appendix to vol. ii.

CITRIC ACID, the acid which gives to the fruits of the citron family their peculiar sour taste. It may be extracted from many fruits and vegetables, as oranges, currants, gooseberries, strawberries, raspberries, whortleberries, tamarinds, onions, and potatoes. The red elder berry contains so much of it that it has been proposed to substitute it in part for limes and lemons, from which the acid is now wholly prepared. The manufacture of citric acid is conducted at but few large establishments; but on a small scale it may be prepared by the same process that is adopted in the large way. Lemon juice is imported in a concentrated state, produced by evaporation at a gentle heat. It consists of citric acid 6 to 7 per cent., alcohol 5 to 6, and the remainder water, inorganic salts, &c. By some it is allowed to partially ferment, for the purpose of evaporating the clear liquor from the mucilage; or it is clarified in the usual method by the use of albumen in the form of the white of egg. Carbonate of lime in fine powder is then gradually added, and stirred in

so long as the effervescence continues. Citrate of lime (an insoluble powder) forms, and after being separated by drawing off the watery liquor is well washed with warm water. This salt is then intimately mixed with strong sulphuric acid diluted with six parts of water. After some hours the citrate is decomposed, the sulphuric acid having taken up the lime and formed an insoluble sulphate, setting the citric acid free. This, separated by decanting and filtering, is evaporated in leaden pans till it attains the specific gravity 1.13. The evaporation is afterward continued by a water or steam bath till the liquor begins to be sirupy, or to be covered with a thin pellicle. It is then instantly removed from the fire, and put aside to crystallize, the mother liquor after a few days being evaporated as above, and again set to crystallize, and so on as long as clean crystals are obtained. To obtain pure citric acid, all the crystals should be redissolved and recrystallized, it may be several times, and the solution digested with bone black. A gallon of lemon juice should make about eight ounces of crystals; more than this is sometimes obtained. Attempts have been made to prepare the citrate of lime for exportation instead of the lemon juice, to reduce the cost of transportation; but its liability to ferment, which destroys the citric acid by converting it into acetic and butyric acids, prevents this method from being employed. Citric acid was first obtained by Scheele in 1784. The crystals are transparent, in the form of rhombic prisms, with summits of four trapezoidal faces. The salt is soluble in water, warm or cold, as also in alcohol, but not in ether. Its specific gravity is 1.6. Its taste is intensely acid, and almost caustic, but still agreeable. It is distinguished from other vegetable acids by its depositing an insoluble citrate when heated with lime water, by the form of its crystals, and also by forming a deliquescent salt with potassa. The crystals are combinations of 1 equivalent of citric acid with either 3, 4, or 5 of water, according to the method and temperature by which they have been obtained. The anhydrous acid, as it exists in the citrate of silver, is represented by the formula $C_6H_8O_7$; but it has never been isolated.—Citric acid is much used at sea as an antiscorbutic, but the raw lemon juice is thought to be more efficient. English vessels are all required by law to carry a certain quantity of the latter for each man employed. It goes to the manufacture of citric acid, as already stated, in a concentrated form; but that intended for the use of ships is protected from fermentation by the addition of some spirit. Citric acid is largely adulterated, sometimes to an almost incredible percentage, with tartaric acid. Acetate of potassa, added to its solution in cold water, will, if tartaric acid be present, throw down a white crystalline precipitate of bitartrate of potassa (cream of tartar). It sometimes also retains some sulphuric acid. Besides its use as an antiscorbutic, citric acid

is employed instead of lemon juice for the preparation of refreshing drinks, and in the arts it is of value to calico printers.

CITRON, the fruit of a low, evergreen tree (*Citrus medica*, Linn.), which belongs to the same genus as the lime, lemon, shaddock, and orange trees, attains in its wild state a height of about 8 ft., and is erect and prickly, with long reclining branches. Its leaves are alternate, oblong-acute, subserrate, and pale green; its petioles are naked, and its flowers 40-androus and externally purple; and its fruit is ovate, about 6 inches long, furrowed, with a protuberance at the tip, and with two rinds, the outer thin, greenish yellow, with numberless miliary glands, full of a most fragrant oil, and the inner thick, fungous, and white. The trees of this genus are among the most brilliant of fruit-bearing trees, are indigenous in the East, and are supposed to be alluded to in the golden apples which the Greeks attributed to the gar-

Citrus medica.

dens of the Hesperides. There is, however, no evidence that any of them were cultivated either by the Greeks or earlier Romans. The citron tree, the most beautiful of them, and the first introduced into Europe, was obtained from Media and perhaps Assyria, and was first cultivated in Italy by Palladius in the 2d century. In the East it is constantly in blossom, flowers and fruit always hanging upon the tree together; at Nice, Genoa, and Naples, and also in the West Indies, it endures the open air, but at Florence and Milan it requires protection in the winter, and in more northern climates it is cultivated in conservatories. In China there is a splendid variety, with large and solid fruit, divided at the end into five distinct lobes, whence it is called by the Chinese the fingered citron. It is kept for its agreeable fragrance on fine porcelain dishes in sitting rooms. The citron is a somewhat acid fruit, rarely eaten raw, and highly valued for its very fragrant rind, which by being preserved in sugar be-

comes a delicate sweetmeat. From the outside of the fruit and the leaves the oil of citron is prepared; the pulp furnishes citric acid; the seeds are very bitter and tonic; and the bark of the root is a febrifuge. There are 12 well known varieties of citron raised in Italy, and about 20 in French and 6 in English nurseries. There are 17 varieties described and figured, and the methods of their culture minutely given, in Risso's *Histoire naturelle des orangers* (Paris, 1818).

CITTÀ VECCHIA, or *Città Notabile*, a city of Malta, situated on high ground almost in the centre of the island, 6 m. W. of Valetta; pop. about 7,000. It contains a fine Roman Catholic cathedral and other churches, vast catacombs, several convents, an episcopal seminary, and an ancient palace of the grand masters of the order of St. John. Previous to the foundation of Valetta, in the latter part of the 16th century, it was the capital of Malta, under its old Arabic name of Medina (the city), and it continues to be the seat of a Roman Catholic bishop. It has lost all strategical importance, though it is walled. Some authorities regard it as identical with the town of Melita mentioned by ancient geographers. Others state that St. Paul, after having been shipwrecked on his journey to Rome, took refuge during three months in a grotto underneath the ancient church, on the site of the present cathedral.

CIUDAD REAL, Mexico. See SAN CRISTÓBAL.

CIUDAD REAL. I. A S. province of Spain, comprising the greater part of the old province of La Mancha, and a portion of New Castile proper; area, 7,837 sq. m.; pop. in 1867, 264,908. It consists mainly of barren plains skirted N. and S. by lofty sierras, some of which are clad with forests, and enclose many deep valleys. They give rise to several rivers, most of them affluents of the Guadiana, which impart fertility to the land in their immediate vicinity. The Guadiana itself, which rises near the border of the province, traverses it from E. to W. Wheat, rye, barley, maize, oats, beans, peas, hemp, flax, aniseed, and esparto are cultivated, and horned cattle, horses, mules, asses, sheep, goats, and pigs are reared. The mountains contain iron, silver, copper, lead, antimony, cinnabar, coal, marble, granite, quartzite, jasper, &c. In the S. W. corner of the province is the famous quicksilver mine of Almaden. Hot and cold mineral springs are abundant. The manufactures include woollens, linen, cotton, silk, hardware, earthenware, saltpetre, soap, wine, oil, and brandy, and the exports consist of these articles, with many of the natural products. The imports are lace, perfumery, sugar, coffee, and rice. Manzanares, Almodovar, Calatrava, and Valdepeñas are among the more important places. II. The capital of the province, situated in a low plain about 5 m. from the Guadiana and 100 m. S. S. W. of Madrid; pop. about 10,000. Built after the expulsion of the Moors from La Mancha to serve as a check upon the

remnant of that people who still maintained themselves in the Sierra Morena, it was originally a place of strength, and yet retains a portion of its ancient defences, which, with its solid-looking houses and rich surrounding vegetation, convey on a distant view a pleasing impression. A closer inspection shows the walls to be ruinous, the town dull and half deserted. The streets, however, are wide, level, and regular; most of the houses have iron railings and balconies, and those facing the principal public square are lined with arcades. The handsomest building is the church of Santa Maria, consisting only of a Gothic nave of magnificent proportions, with a high stone tower. There are several other churches, six monasteries, three nunneries, hospitals, a secondary college, a superior school, a house of refuge for juvenile vagrants, and fine barracks. It is the seat of a bishopric. The manufactures consist chiefly of coarse strong woollens, linens, table cloths, and watches. Trade is confined principally to grain, potatoes, wine, fruits, and mules. The railway from Madrid to Badajoz passes through it. Before the final conquest of Granada this was a frontier city and seat of the court of chancery for the south. It was the headquarters of the *Hermadad*, or holy brotherhood, founded in 1249, for the suppression of highway robbery. A battle was fought in the vicinity, March 27, 1809, in which Gen. Sébastiani, with 12,000 men, gained an easy victory over 19,000 Spaniards commanded by Urbino, count of Cartoajal. The Spaniards lost 1,000 killed, 3,000 prisoners, and a quantity of arms and provisions.

CIUDAD RODRIGO, a town of Spain, in the province and 44 m. S. W. of Salamanca, situated on the right bank of the Agueda, 15 m. from the Portuguese boundary; pop. about 6,500. It occupies one of the most important positions on the frontiers of Spain, and is fortified by walls, a ditch, a castle, and other works, ranking as a fortress of the second class. It derives its name from its founder, Count Rodrigo Gonzales Giron, who lived about the middle of the 12th century. It is indifferently built, but has a few interesting structures, including the cathedral, a cruciform edifice which has suffered somewhat from sieges, the chapel of Cerralbo, still beautiful despite its dilapidation, an Augustinian convent and church, and a handsome bridge of seven arches across the Agueda, connecting the city with its suburbs. In the market place are three Roman columns with inscriptions, brought from ancient Malabriga, and borne by the city for its arms. It occupies a prominent place in the early annals of Spain, but its present historical importance depends mainly upon the events of the peninsular war. In 1810 it was invested by the French under Masséna, was gallantly defended by the Spanish garrison, and after a siege of about 40 days was forced to capitulate. On Jan. 8, 1812, Wellington suddenly crossed the Agueda, carried one of the advanced redoubts

by assault, established his batteries, and on the 14th commenced a furious bombardment. On the 19th two breaches were declared practicable, and on that night the town was stormed in the face of a murderous fire. By this exploit the British captured 150 guns and a vast amount of stores, but lost 1,300 men. The French lost 300 killed and 1,500 prisoners. Wellington was created duke of Ciudad Rodrigo by Spain, marquis of Torres Vedras by Portugal, and raised from viscount to earl by his own government.

CIVET (*viverra civetta*, Linn.), a digitigrade carnivorous mammal, belonging to the family *viverrida*, inhabiting northern Africa. The dentition is less carnivorous than that of the cats, there being three false molars above and

Civet (*Viverra civetta*).

four below, the anterior of which occasionally drops out; two tuberculous, tolerably large above, and one only below; the lower carnivorous tooth has even two projecting tubercles on the inner side in front, and the whole of it is more or less tuberculous. The tongue is rough, the claws are partly straightened in walking, and between the anus and the genital opening is a sac, divided into two parts, lined with glands which secrete an unctuous substance of a strong musk-like odor. The civet is about 2½ ft. long from the nose to the end of the tail, the latter being more than a foot of this length; and the height is about 15 inches. The general color is an iron gray, with transverse black bands, narrow and parallel on the shoulders, wider on the body and thighs, and sometimes forming curved eye-like spots; the tail has four or five blackish rings, and the last six inches entirely black; the neck is whitish, with three black bands; the muzzle is black, except the upper lip, which is white, and there is no spot under the eye as in the zibeth; the limbs are black; along the back is a strong, stiff, erectile mane; the fore part of the ears is grayish white and the hind part black; the under parts are white, the hairs being dark at the base. These colors vary somewhat in different specimens. According to Cuvier, the cavities which contain the scent have their internal surface slightly covered with fine hair and pierced with many holes, the openings of superficial oval follicles, whose cavities receive

the odorous substance and discharge it into the main bag in a vermicelli-like form; the follicles as well as the bag may be compressed by muscular action at the will of the animal. Besides this, the civet secretes a dark-colored fetid liquid, which issues from an opening on each side of the anus. In Abyssinia and some parts of Asia the civet is kept in considerable numbers in a state of domestication for the sake of its musky secretion. In confinement it is a very sleepy animal, doing nothing but eat and sleep. When irritated, the musky odor becomes stronger. When the bag becomes filled with the hardened secretion, it falls out in pieces about the size of an almond. When first secreted it is semi-liquid and yellowish in color, becoming harder and brown on exposure to the air; the taste is bitter and the odor less agreeable than musk. It is insoluble in water, slightly soluble in ether and cold alcohol, and almost entirely so in hot alcohol. It contains a volatile oil and free ammonia. Formerly it was highly esteemed as a stimulant and antispasmodic medicine, but castor and musk, also animal secretions, have taken its place, and its use is now confined to the manufacture of perfumery. In its wild state the civet is a nocturnal animal, preying upon the smaller mammals, birds, and reptiles, and occasionally eating fruits; in confinement its food is more varied.—The zibeth and the rasse (*V. zibetta*, Linn., and *V. rasse*, Horsf.), the former inhabiting the Asiatic continent and the latter the islands of the Indian archipelago, especially Java, both secrete an odorous substance like civet, a favorite perfume in the East; it is now less esteemed in Europe than musk.—This family is represented in America by the civet cat, or *cacomixl* of the Mexicans (*bassaris astuta*, Licht.), about as large as a cat, but more slender. It is brownish yellow above, mixed with

Civet Cat (*Bassaris astuta*).

gray below, the tail white with six to eight black rings, rather full. It is an arboreal animal, and is easily tamed.

CIVIALE, Jean, a French surgeon, the originator of the modern operation of lithotripsy, born near Thiézac, Auvergne, in 1792, died in Paris, June 13, 1867. At a very early age,

while a pupil of Dupuytren at the Hôtel Dieu hospital in Paris, his attention is said to have been attracted to the subject of his future discovery; and after many years of perseverance he succeeded, not without encountering opposition and even ridicule, in perfecting his ideas, and introducing to the profession his new operation of lithotrity, *i. e.*, crushing stone in the bladder and removing it by the natural passages. Before that time the only means of extracting from the bladder a calculus of considerable size, was the serious and often dangerous operation of lithotomy. (See STONE.) He was the teacher of several generations of lithotritists, both of his own and other countries, and became a member of the medical academy, an associate member of the institute, and an officer of the legion of honor. His principal publications are: *De la lithotritie, ou broiement de la pierre* (Paris, 1827); *Lettres sur la lithotritie, &c.* (1827); *Traité pratique et historique de la lithotritie* (1847); *Résultats cliniques de la lithotritie pendant les années 1860-64* (1865). At the time of his death he had nearly finished *Guide pratique pour les opérations de la taille et de la lithotritie*, since published under the direction of M. Guardia, the deputy librarian of the academy of medicine, with a biographical sketch, and *L'Histoire de la lithotritie, d'après des documents inédits*.

CIVIL LAW, the positive municipal law of the Roman empire, as comprised in the collections made by order of the emperor Justinian (530-33) and published by his authority. These collections were the Institutes, the Digest (Pandects), the Code, and the Novellæ, which, comprised in one work, are called the *Corpus Juris Civilis*, by way of distinction from the canon law. The Roman law in general comprehends all the laws which prevailed among the ancient Romans, without regard to the time of their origin. The Roman jurists used the term civil law, *jus civile*, to designate the law applicable to Roman citizens only, in contradistinction to the law applicable to aliens, which was called *jus gentium*, the laws of other nations. With regard to its object, the Romans divided the law (*jus*) into public and private. The public law comprehended those rules of law which relate to the constitution and government of the state, and the relations of the people to the government. The private law comprehended those rules which pertained to the judicial relations of citizens among themselves. The private law was again divided into *jus naturale*, *jus gentium*, and *jus civile* (natural law, the laws of other nations, and civil law). *Jus naturale* was the name given to that law which is derived from the animal nature of man, and from those instincts which he has in common with the brute creation. *Jus gentium* denoted that law which is founded upon the rational nature of man, and which on this account was recognized by all the civilized nations of the time. By *jus civile* they under-

stood that part of the private law which was established by the state, and the enactments of which, according to Ulpian, neither totally deviate from the *jus naturale* and *jus gentium*, nor entirely follow them; but which sometimes add to and sometimes subtract from them. Hence, in the *jus naturale* man is regarded as an animal, in the *jus gentium* as a rational being, and in the *jus civile* as a member of an individual community or body politic. The civil law was subdivided into written and unwritten. By the term written law was understood that which was actually committed to writing, whether it had originated by enactment or by custom, in contradistinction to such parts of the law of custom as were not committed to writing. Hence among the Romans the prætorian edicts (*edicta prætorum*) and the legal opinions of jurists (*responsa prudentum*) belonged to the written law. The law introduced by the prætors and ædiles, through their edicts, was denominated *jus honorarium* (honorary law), called so no doubt from the public offices with which the prætors and ædiles were invested, and from which that law issued; and hence signifying law delivered by the magistrates, as contradistinguished from the strict civil law of the twelve tables and the law of custom. In order to obtain a full insight into the Roman law, and the civil law as preserved in the collections of Justinian, it is necessary to consider its origin, its history, and its gradual development.—The history of the Roman law may be divided into four periods, as first distinguished by Gibbon in his "History of the Decline and Fall of the Roman Empire." The first period extends from the foundation of Rome to the adoption of the twelve tables, A. U. C. 1 to about 300; the second thence to Cicero, about A. U. C. 650; the third, from Cicero to Alexander Severus, about A. U. C. 1000; the fourth, from Alexander Severus to Justinian, about A. U. C. 1300.—*First Period*, A. U. C. 1-300. During four fifths of this time the form of government was a monarchy. A king elected for life was the head of the state, and joined to him was a senate, consisting of patricians only. The legislative power remained with the people, and was exercised by them in their national assemblies (*comitia*). The king and senate were each entitled to propose laws, which were then discussed and voted upon in the meetings of the people, at first by *curiæ*, which were formed solely by the patricians; in later times by *centuriæ*, of which the plebeians also were members, whereby they first obtained some political importance and share in legislation. The laws proposed, if adopted in these meetings of the people, obtained legal force, and were known as *leges curiatae* or *centuriatae*. The ancient *leges curiatae* are said to have been collected in the time of Tarquin the Proud, the last of the kings, by a pontifex maximus named Sextus or Publius Papirius. The existing fragments

of this collection are few and of very doubtful character. After the kings were expelled, A. U. C. 244, Rome became a republic, and two consuls elected annually were substituted for the king. The adoption of laws and the election of magistrates now took place in the *comitia centuriata*, in which the patricians by their rank and wealth overbalanced the plebeians. Therefore the tribunes of the plebs (A. U. C. 260) were established, chosen from the plebeians to protect their rights. They had at first only the right to protest against the decrees of the consuls and the senate, and to render them ineffective by their veto; but they soon after acquired also the right, as chiefs of the plebeians, to propose laws to them in the *comitia tributa*, which were only subjected to the discussion and suffrage of the plebeians. These laws were called *plebiscita*. Besides the tribunes, two other magistrates of their own, called *ædiles*, were at the same time granted to the plebeians. Their duty was to take charge of the police, and attend to the public welfare in respect of certain edifices and archives. From all other higher offices the plebeians continued to be excluded, and it was not till the second period that the dignities of consul, *ædilis*, *curulis*, dictator, censor, prætor, and at last even that of pontifex, became accessible to them. About A. U. C. 300 the celebrated law of the twelve tables was enacted. This law bears the character not of a new civil code, but rather of a constitution, being, as it were, an act of capitulation of each class to the other. Its main purpose was to establish by law the equality of the patricians and plebeians; to define the limits of the judicial power, then in the hands of the consuls; and to regulate judicial proceedings. Moreover, a large part of the private law, as it had existed for a long time previous, was now committed to writing; and thus the twelve tables formed a compilation in writing of the customary law existing at that time. Generally speaking, details were omitted and principles only were embodied; but in some instances, as for example the rules for observance of funeral services, the laws and obligations between neighbors, and the conduct of the creditor toward his debtors, they descend into minute details. At the same time the old laws peculiar to the different tribes were merged in one national system. This law of the twelve tables, adopted in the *comitia centuriata*, acquired great authority, and constituted the foundation of all the public and private law of the Romans subsequently, until the time of Justinian. By way of distinction it is sometimes called *lex*, law, or *lex decemviris*, law of the ten commissioners. The twelve tables were originally engraved upon wood or ivory, and publicly exposed before the rostra that they might be read by every one. After the devastation of Rome by the Gauls (A. U. C. 364), they were engraved on brass, and were found thus exposed in the 3d century of the Christian era. But we have now only frag-

ments of them, collected from the commentaries of Gaius, contained in the Pandects, from Ulpian's fragments, and from Festus *De Verborum Significatione*. The Institutes of Gaius (discovered A. D. 1816) and the Vatican Fragments (1823) have also supplied some genuine passages previously unknown.—*Second Period*, A. U. C. 300–650. The sources from which the law of the twelve tables and the unwritten law were supplied and developed were principally two, the written law and the unwritten law, that is, the law established by custom. The improvement of the law was effected by the judges and lawyers. The written law comprised the law decreed by the people (*leges*), the *plebiscita*, and the decrees of the senate (*senatus consulta*). The decrees of the Roman people were laws proposed by a magistrate presiding in the senate, and adopted by the people in the *comitia centuriata*. These related principally to the public law. The *plebiscita* were laws proposed by one of the tribunes, and passed by the plebeians alone, in the *comitia tributa*, independently of the patricians. They were at first binding only on the plebeians, until in A. U. C. 305 a law was passed that they should be binding on the whole people. The *plebiscita* related more to private law. The decrees of the senate had generally reference to public laws. The tribunes had the right to protest against them. The law of custom related to private law. The kinds of this law were, the manners and customs of their ancestors, and transmitted to their descendants (*mores majorum*); the law which originated from the opinions and usages of the people (*consuetudo*); and the law formed by uniform judicial decisions in similar cases, and which the French call *la jurisprudence des arrêts*, and the Germans call *Praktik*, or judicial usage (*usus fori*), and which is in England and the United States the common law, as declared and established by the decisions of the highest tribunals. The greatest influence upon the development of the law was exercised by the prætors and other higher magistrates through their edicts, and by the lawyers through their commentaries on them, and their practical application of them to cases. The supreme judicial power was originally vested in the kings, and afterward in the consuls, who exercised it personally. After A. U. C. 387, a new magistrate for the administration of civil justice was established at Rome, under the title of city prætor (*prætor urbanus*). This word is derived from *præire*, to go before, and was in use in Latium to designate the chief magistrate of a city. His jurisdiction was at first restricted to cases in which both parties were Roman citizens; but the continual increase of strangers residing at Rome led to the appointment of another prætor about A. U. C. 508, to decide in cases of lawsuits of the non-Romans among themselves, or with Romans, and who was called *prætor peregrinus* (the prætor for strangers). The Roman law proper was applicable

to Roman citizens only. The system of general law principles acknowledged by the civilized nations of that time was called the *jus gentium* (law of other nations), and this law was applied to the non-Romans. It may be called a universal natural law, based on reason only. The use was soon extended to the Romans also, and the strict Roman civil law was modified by it. This change was effected chiefly by the edicts of the prætors. From the earliest periods the consuls, and later the prætors, the curule ædiles, the censors, and even the plebeian tribunes, had the right of publishing orders and notices connected with their respective functions; this right was styled the right to publish or declare (*edicere*). The use of this expression, however, more particularly belonged to those magistrates who had a certain jurisdiction; *e. g.*, the prætors and the two ædiles, and in the provinces the governor. Their jurisdiction consisted in the general capacity to declare the law. The prætors, when entering on their office, published an edict whereby they made known those legal principles on which they would administer law and justice, and the mode of proceeding which they would observe during the year of their office. By these edicts they seldom introduced new principles of law, but generally confirmed those which were established by usage and public opinion. Where they found deficiencies in the existing law, or deemed it no longer applicable to the times, they established the rules which they would follow in their decisions. They softened the rigor of the strict civil law, so that it might harmonize with equity. This edict which the prætor published on entering upon his office was called the perpetual edict, because it was not made for a particular case, but, although annual, was for the perpetual jurisdiction in all cases that might come before him during his year of office. Those decisions which had been established by custom, and transmitted from edict to edict, formed what was called the honorary law (*jus honorarium*). This is the origin of that prætorian law which advanced parallel with the Roman civil law; it was grounded on equity and natural justice. It was a work of science, of philosophy, and of progress, and supplanted the primitive Quiritarian law. The care of the police was intrusted to the magistrates called *ædiles*, as before stated. They, like the prætors, published their edict on entering upon their office. The law introduced by them, together with that of the prætors, belonged to the honorary law above alluded to. The lawyers assisted in developing the law by interpretation and legal opinions, called *responsa*. The law thus introduced by jurists was called *authoritas prudentum* or *jus receptum*. There are few traces of legal works of a scientific character to be found in this period. At first only the patricians and pontifices had an intimate acquaintance with the existing law, and especially with the system of actions, the forms

of proceeding, and the times at which the courts were held (*dies fasti et nefasti*). Cn. Flavius, a clerk of the lawyer Appius Claudius (A. U. C. 450), published a book in which Claudius had composed and arranged the law actions; this book was called *Jus Flavianum*. The elder Cato wrote commentaries on the civil law and legal opinions. Among other distinguished lawyers were his son Cato Licinianus, Marcus Junius Brutus, and Manilius.—*Third Period*, A. U. C. 650–1000. After the battle of Actium (31 B. C.) Octavius Cæsar became, as *princeps reipublicæ*, under the surname of Augustus, the sovereign of the state, by uniting in his person the most important of the old republican offices. He still observed the old forms; but under his successors even these forms gradually disappeared; the power of the *principes* or emperors grew more and more absolute, and finally became despotism. The right of legislation was transferred by degrees from the people to the emperor, whose *constitutiones* soon began to supply the public as well as private law. The sources of law during this period were: 1, the decrees of the people; 2, those of the senate; 3, the constitutions of the emperors; 4, the prætorian edict; 5, the legal opinions of jurists; 6, the writings of the law commentators. 1. The decrees of the people, which still continued to be either *leges* or *plebiscita*, were never made in greater numbers than in the beginning, during the civil wars. Many among them were and continued to be important to the private law, *e. g.*, the *lex Julia et Papia Poppæa*, made under Augustus. But they became fewer as the supreme power of the emperors increased; and toward the end of this period they cease to be mentioned. 2. The decrees of the senate increased in number as those of the people decreased, and acquired a much greater importance than ever before. They now began to be named after either the consul who had proposed them, or the emperor himself, who made the motion in writing or orally, and sometimes after the person who had occasioned them; for instance, *senatus consultum Silanianum*, under Augustus; *senatus consultum Trebellianum*, under Nero. 3. When the Roman state had ceased to be a republic in fact, and several of the highest offices were united in the person of the emperor for his lifetime, he began, in imitation of the ancient republican magistrates, to issue ordinances and regulations by virtue of the power conferred on him. Such ordinances were called *placita* or constitutions of the emperor. When appeals from the ordinary courts came to be made to the emperors directly, they were soon induced to appoint a body composed of the higher state officers and jurists, to which they transferred the cases and questions presented to them for decision or opinion. This was called *auditorium principis*, and it soon became the supreme court for the whole empire. Its sentences and decisions, issued in the name of the emperor, were called *decreta*; and its legal

opinions, given either to private persons or officers, *rescripta*. There were four classes of constitutions: orations (addressed to the senate and requiring it to issue *senatus consulta*), edicts, mandates, rescripts, and decrees. The decrees and rescripts were generally made known through the *acta diurna* or daily papers, and may be compared to the *arrêts* of the kings of France. 4. The prætors and ædiles of Rome, as well as the proconsuls and prætors in the provinces, continued during this period to publish edicts on entering upon their offices. As many of them, however, probably took the liberty to deviate from them during their term of office, the tribune Cornelius (A. U. C. 687) procured the passage of a law prescribing that they should administer the law in accordance with their edicts. However, the importance of their edicts as a source of private law was much reduced. The prætorian edict formed for a long time a chief source of the private law, and became therefore a subject of literary disquisition and instruction. The want of uniformity in its plan, and the disregard of coherence shown in its gradual alteration and enlargement, rendered it necessary to reduce it to something like a system. The first who undertook this labor was Ofilius, a friend of Julius Cæsar; but this being the work of a private jurist, it was without legal authority. A revision of such a work was needed, but was not effected until the time of Hadrian (A. D. 117-138), when it was undertaken by Salvius Julianus, a distinguished jurist, who was also prætor, by order of that emperor. He was authorized to omit, to amend, and to add. The edict of the ædiles, which related chiefly to the police, was retained separately in an appendix. Hadrian caused this new revision to be confirmed by a special decree of the senate (131). From that time the edict remained substantially the same, and became a principal subject of legal instruction. Julian himself wrote commentaries upon it; and after him many others, among whom Ulpian deserves special mention. Only fragments of the edict are left. 5. From the earliest times it was a custom among the Romans, in doubtful cases, for private individuals as well as the magistrates themselves to apply to the jurists and request their legal opinions, called *responsa*. Before the time of Augustus, the responses thus given were merely lawyers' opinions, and had no legal authority. Augustus first allowed several distinguished jurists, by special grant, to respond in his name; and naturally the opinions given by them acquired a greater authority. Hadrian afterward ordered that the unanimous opinion of the jurists especially authorized to respond should have the force of law, and should be followed by the judges; but that in case their opinions disagreed, the judge should follow that opinion which he himself considered the most just. 6. In the scientific treatment and illustration of the law, this period surpassed all others both for the variety

and profoundness of its works. It is distinguished by the most eminent jurists that ever existed among the Romans, and they advanced the science of the law to a high degree of perfection, and are therefore usually called the classical jurists. Their writings contained excellent explanations and exhibitions of the law sources, and soon obtained a decisive authority in the courts, because the assistance of learned interpreters of the law was indispensable in applying the twelve tables and the edict to practice. The Pandects of Justinian were compiled from the writings of these jurists. The most distinguished jurists before Augustus were Q. Mucius Sævola, Aquilius Gallus, M. Tullius Cicero, Sextus Papirius, Ofilius, Trebatius Testa, and others. After the time of Augustus the Roman jurists specially authorized to respond on the law seem to have divided themselves into certain schools or legal sects. These schools, however, appear to have been only separate academies or offices (*stationes*) for giving legal opinions. The professors and chiefs of these differed in their elementary views, and were followed therein by their scholars for several generations. Many controversies arose therefrom, which were subsequently settled by imperial constitutions or by judicial decisions. The most eminent founders and adherents of these sects were Antistius Labeo, Proculus, Juventius Celsus, and Salvius Julianus. The most distinguished jurists after the time of Hadrian were Papirius Justus, Terentius Clemens, Ulpian Marcellus, and most particularly Gaius Æmilius Papinianus, Domitius Ulpianus, Julius Paulus, and Modestinus. Jurists of less celebrity, although their writings have been compiled from, are Tertulianus, Licinius Rufinus, Rutilius Maximus, and others. The Institutes of Gaius are his most important work to us, because they formed the foundation of the Institutes of Justinian. They were discovered in 1816 by Niebuhr in a *codex rescriptus* at Verona. Most of the writings of Ulpian have been quoted in the Pandects; other parts are to be found in the *Fragmenta Vaticana*.—*Fourth Period*, A. U. C. 1000-1300. After the death of Alexander Severus (235) the Roman empire hastened rapidly to its complete fall. The confusion reached its greatest height when under Valerian (253-260) the Alemanni, the Franks, the Goths, and the Heruli invaded the Roman provinces. Constantine (306-337) founded on the shores of the Bosphorus a new seat of empire, where he then took up his abode. From this time the Christian religion became predominant, and the Latin language was gradually displaced by the Greek. Such important changes could not take place without great influence upon the Roman laws. The empire was divided anew under the sons of Constantine, and again (395) under the sons of Theodosius, of whom Arcadius obtained the East and Honorius the West. In the commencement of the 5th century Alaric, king of the Visigoths, made an attack upon Italy, and

plundered Rome; the Alans, Vandals, and Suevi advanced through Gaul to the Pyrenean peninsula, and thence to Africa; the Franks, Burgundians, and Ostrogoths took possession of Gaul, Helvetia, and the country bordering on the Rhine; while Britain became occupied by the Saxons, and Attila (about 450) invaded Gaul with his Huns, who everywhere carried destruction in their path. The Western empire was at last completely terminated by Odoacer (476). The power of the Romans was now limited to the empire of the East, which continued to the year 1453, when it was destroyed by the Turks. In this period the alterations of the law were almost exclusively effected by imperial ordinances and by customs. Most of them related to the administration of government, especially the finances, the war department, and the provinces; and the few relating to private law were usually only an application of the existing law to particular cases and persons. They were either general ordinances relating to the whole people, namely, edicts or personal constitutions, establishing provisions for single persons, as for instance privileges or mandates, imperial orders and directions for the officers of state, and decisions in judicial cases (*decreta*) which had been brought by way of appeal before the imperial council (*auditorium principis*), or answers and directions of the emperors (*rescripta*) upon applications or questions in doubtful cases, which were given, on the opinion of the imperial council, in conformity with the existing law. Before Constantine, most of the imperial ordinances were merely decrees and rescripts; but subsequently the edicts became very frequent, for the prevalence of Christianity had changed many of the former opinions of the nation, and the manners and language of the East, where the metropolis was placed, differed widely from those of the West. At the commencement of the 5th century the sources of law were at least theoretically as follows: 1, the ancient decrees of the people; 2, the decrees of the senate; 3, the edicts of the Roman magistrates; 4, the ordinances of the emperors; 5, the unwritten customs. The law of the twelve tables still formed the basis of the whole, and all the laws of later times had to them the relation of additions and modifications. But in practice only the writings of the classical jurists and the constitutions of the emperors were used as sources. Constantine determined by special ordinances what writings of the old jurists should have particular authority, and what should not be regarded. He prohibited reference to the notes of Ulpian and Paulus on Papinian. A century later (426) Theodosius II. issued a similar and yet more extensive ordinance, which was intended for the Eastern empire, but soon after obtained legal force also in the Western. This ordinance (which is often erroneously attributed to Valentinian III., and hence called Valentinian's law of quotation) provided that all the writ-

tings of Papinian, Paulus, Gaius, Ulpian, and Modestinus should have the force of legal authority. The same authority was extended to all those older jurists whose opinions and treatises were incorporated into and explained by the writings of the five abovenamed, with the exception only of the notes of Ulpian and Paulus on Papinian. In case of the disagreement of those authorities, the majority were to decide; where the opinions were equally divided, that of Papinian was to have the preference; but where he was silent, the judge was to follow his own opinion.—The constitutions of the emperors were very numerous. Two jurists, Gregorius and Hermogenes, or according to others Gregorianus and Hermogenianus, in the early part of the 4th century, undertook two collections (*codices*) of imperial constitutions. Both collections, however, were almost exclusively composed of rescripts. The *Codex Gregorianus* contained the constitutions from Hadrian down to Constantine. The *Codex Hermogenianus* was only a supplement to the former, containing the constitutions of Diocletian and Maximinian. Only a few fragments are left of these collections. The *Codex Theodosianus* was of greater importance than either of the foregoing. By an ordinance of the emperor Theodosius the Younger, a committee of 16 jurists, of whom the ex-consul and ex-prefectus prætorio Antiochus was the chief, made a collection of the edicts of the emperors, including however many of the rescripts. This collection was published in 438, as a code for the Eastern empire. Theodosius sent this new code to his son-in-law Valentinian III., who confirmed it in the same year for the Western empire, and presented it to the senate at Rome, who received it with acclamation. It consisted of 16 books. The work has been recovered almost entire. After the completion of the *Codex Theodosianus*, the emperors Theodosius II., Valentinian III., and their successors, continued to issue new ordinances, which are termed *novellæ*, i. e., *novæ constitutiones* (new constitutions). These have been embodied in later times in the *Codex Theodosianus*, under the head of *Novellæ Constitutiones Imperatorum, Justiniano anteriorum, Theodosii, Valentiniani, &c.* From the time of Alexander Severus to Justinian there were hardly any writers on law of any importance. The literary productions were confined to collecting imperial constitutions, and compiling from the works of the old jurists.—After the fall of the Roman empire several new German states were formed in the West, in which the immigrated Germans and the conquered Romans lived together under the same government. The former had separate laws and customs of their own, which they preserved in their new settlements; while the subdued Romans, living among them, continued to use their own, and were judged according to them. The Germans committed to writing their primitive national laws, and the Romans did the same with their laws then in force. The most

important of those new Roman law collections among the German nations are: 1. The edict of Theodoric, king of the Ostrogoths, which he issued in Rome in 500, intended not only for the conquered Romans, but also for the Ostrogoths. This edict is derived entirely from the Roman law, and especially from the *Codex Theodosianus*, the later novels, and *Pauli Sententiæ receptæ*. But these sources were used so arbitrarily, that the character of the Roman law can scarcely be traced in them. 2. The *Breviarium Alaricianum* among the Visigoths. Alaric II., king of the Visigoths, published in 506 a code of laws affecting only the Romans living in his kingdom, which had been collected under his order by a committee of 16 Roman lawyers, from the *Codices Gregorianus*, *Hermogenianus*, and *Theodosianus*, as well as from some of the later novels, and from the writings of Gaius, Paulus, and Papinianus. Most of the passages are accompanied by a paraphrase (interpretation), in very bad Latin, but which was then intelligible. This Visigothic collection is now called *Breviarium Alaricianum* or *Brevarium Aniani*, from Anian, the private secretary of Alaric, who was ordered to authenticate by his signature the copies of the *Breviarium* sent to the magistrates of the counties. In the middle ages it is commonly referred to under the titles *Corpus Theodosianum*, *Lex Theodosiana*, *Liber Legum*, or *Lex Romana*. 3. Between the years 517 and 534 a *Lex Romana* was also published among the Burgundians, intended for the Roman subjects in the Burgundian empire, and which is known by the name of *Papiani Liber Responsorum*, or *Papiani Responsum*. The greater part of this collection is derived immediately from the pure sources of Roman law. After the time of Theodosius II. nothing was done in the East to facilitate the administration and study of the law until Justinian became emperor in 527. During the 38 years of his government (527-565) he made legislation and the promotion of the study of the law the principal objects of his attention; and fortunately he found jurists possessed of the knowledge and abilities requisite for his purpose. They made by his order those collections of law which continue in legal force in many countries to the present day. Justinian was the first after Theodosius who undertook a new collection of the imperial constitutions, which was intended to form a substitute for all previous collections. He appointed a committee of ten lawyers with very extensive powers. At their head was the ex-quæstor of the palace Johannes, and among them the well known lawyer Tribonian. His instructions were to select in the briefest manner all that was still of value in the existing collections, as well as in the later constitutions; to omit all obsolete matter; to introduce such alterations as were required by the times; and to divide the whole into appropriate titles. Within 14 months the committee had finished their labors. Justinian confirmed

this new code, which consisted of 12 books, by a special ordinance, and prohibited the use of the older collections of rescripts and edicts. This first code of Justinian, which is now called *Codex Vetus*, has been entirely lost.—*The Pandects*. After the above mentioned code was completed, Justinian ordered Tribonian (530), who was now quæstor, and 16 other jurists, to select all the most valuable passages from the writings of the old jurists which were considered as authoritative, and to arrange them according to their subjects under suitable heads. In regard to the writings from which they should extract, they were exempted from the Theodosian law of citation, and were not confined to the letter of the writings selected, but were allowed at their discretion to abbreviate, to add, and to make such alterations as they considered adapted to the times; and they were especially ordered to remove all contradictions of the old jurists, to avoid all repetitions, and to omit all that had become entirely obsolete. The consequence of this was, that the extracts did not everywhere truly represent the original, but were often interpolated and amended in conformity to the existing law. Alterations, modifications, and additions of this kind are now usually called *emblemata Triboniani*. This great work was completed by the commissioners in three years. They had extracted from the writings of no fewer than 39 jurists all that they considered valuable for the purpose of this compilation. Over every extract, which regularly consists of a *principium* and one or more paragraphs, a heading (*inscriptio*) was placed, containing the name of the work from which it was derived. The whole compilation, consisting of 50 books, was entitled "Digest or Pandects of the Eliminated Law, collected from all the ancient Law." The word Pandects is derived from the Greek πᾶν, all, and δέχομαι, to receive, because all that was valuable was to be comprised in them. This work was intended for practical use. The arrangement of the titles follows as closely as possible the order of the edict. Justinian divided the whole work into seven parts. The editors of the Pandects divided into three classes all the books from which extracts were to be made, and formed themselves into three sections. The first section read and extracted from the books on the civil law, to which belonged the books on Sabinus; the second section extracted from the books on the prætorian edict, especially from Ulpian on edicts; and the third section, from practical and casuistical writings, especially from *Papiniani Responsa* and Paulus's legal questions. Three branches of extracts were thus formed, the Sabinus branch, the edict branch, and the Papinian branch. From these three branches the single titles of the Pandects were composed. The foundation of each title was generally formed by that branch which furnished the most numerous and important fragments. The Pan-

dicts were published by Justinian Dec. 16, 533; but they were not to have legal authority till Dec. 30. At the same time Justinian prohibited all further reference to the older jurists, forbade the writing of any commentaries upon the new compilation, and only permitted the making of literal translations into Greek, and the publication of parallel passages, with a summary table of their contents. In preparing the Pandects the compilers met very frequently with controversies in the writings of the jurists. Where they themselves did not venture to determine the questions in controversy, they presented them to Justinian for his special decision. Such questions, to the number of 34, had been already determined by Justinian before the commencement of the collection of the Pandects; and before its completion the decisions of this kind were increased to 50. These were embodied in the code. For the purpose of providing a more compendious book for beginners in the study of the law, Justinian ordered Tribonian, with the assistance of Theophilus and Dorotheus, to prepare a brief system of law, under the title of Institutes, which should contain the elements of legal science. They were charged to make the law then applicable their principal object; but they were also to pay some attention to the older laws. This work was founded on the Institutes of Gaius, from which all that was entirely obsolete was omitted, and the new constitutions of Justinian, as far as they had been issued at the time, were referred to. Justinian published the Institutes Nov. 21, 533, and they obtained legal force at the same time with the Pandects, Dec. 30, 533. After the publication of the Pandects and the Institutes, Justinian undertook a revision of the code which had been published in 529, because he had issued since that time a great number of new constitutions, and especially the 50 decisions, which were not comprised in the old code, and by which the law contained in the Pandects had been augmented, altered, or defined. He therefore in 534 ordered Tribonian, with the assistance of Dorotheus, Menna, Constantinus, and Johannes, to revise the old code, and to add the new constitutions. This revision was completed in the same year, and the new edition of the code (*Codez repetita Prælectionis*) was confirmed Nov. 16, 534, and the old code abolished. This new code contains only imperial constitutions, which from the time of Hadrian up to Constantine consist almost exclusively of rescripts, but from Constantine to Justinian are chiefly edicts or general laws. The code consists of 12 books, which are subdivided into titles, and in these the single constitutions relating to the same subject are arranged in chronological order.—*Manner of citing the Pandects.* There still continue to be different ways of citing the Pandects. Formerly it was usual to cite, for instance: *D. de jure dotium, L. profectitia, § Si Pater*; or, vice versa, *L. profectitia, § Si Pater, D. de jure*

dotium. From this afterward originated the following: *L. profectitia* 5, § *Si Pater* 6, *D. de jure dotium*; and lastly, *L. 5, § 6, D. de jure dotium.* This last form is most commonly used at present, but many, more accurately, prefer *Fr. (fragmentum)*, instead of *L.*; and most jurists add at the end, in a parenthesis, the number of the book and title; thus, *Fr. § 6, D. de jure dotium* (23, 3). In referring to the *principium* of a fragment, *pr.* is put in the place of the mark and number of the section; for example: *Fr. 5, pr. D. de jure dotium* (23, 3). Many, however cite only by numbers: *Fr. 5, § 6, D. 23, 5.* To indicate the Pandects the sign *ff.* is used, which is supposed to be derived from the Greek *II*, or from the symbol of the copyists representing *D.* The Institutes consist of four books, each of which contains several titles; each title commences with a *principium*, after which the single paragraphs follow. Formerly the Institutes were cited by the heading of the title and the initial words of the paragraphs; thus: § *Fratris vero, J. de nuptiis.* At present it is usual to give the heading of the title and the number of the paragraph: *F. § 3, J. de nuptiis*; or by numbers only: § 3, *J. 1, 10*; or, § 3, *J. de nuptiis* (1, 10). In referring to the *principia* of a title the abbreviation *pr.* is used: *pr. J. de nuptiis* (1, 10). The manner of citing the code is like that of the Pandects: *L. 22, C. mandati vel contra.* It is more correct to use *Const. (constitutio)* instead of *L.*, and to cite simply: *Const. 22, C. 4, 35*; or, *Const. 22, C. mandati vel contra* (4, 35). The novels are cited simply according to their number: *Nov. 113, cap. 1.*—During the long continuance of Justinian's government after the publication of the *Codez repetita Prælectionis* (535–565), he issued at different times a great number of new constitutions, by which the law on many subjects was entirely changed. The greatest part of these new constitutions were written in Greek, in obscure and pompous language, and published under the name of *Novellæ Constitutiones.* Soon after his death a collection of 168 novels was made, 154 of which had been issued by Justinian and the others by his successors. Afterward the glossators brought the novels into a collection of nine parts; in which, however, they embodied only 97 novels, because the others were considered no longer applicable. Soon after Justinian's death Julian composed a copious Latin extract from 125 novels, which is known under the name of *Epitome Novellarum* or *Liber Novellarum.* About the same time a Latin translation of the novels was made by an anonymous author, which contains only 134 novels. This translation, now termed *Versio vulgata*, was called by the glossators the *Corpus authenticum*, in order to distinguish it from the *Epitome Juliani.*—As the Latin language was not generally used among the Byzantines, Justinian's law collections were translated into Greek. Numerous constitutions were issued by his successors; and although he had ex-

pressly forbidden comments on his collections, the later jurists disregarded this prohibition, and a great number of Greek commentaries on Justinian's law collections were published, which had special reference to the alterations made in the East after his time. Hence the science of law became again so diffuse, that three centuries later (887) a new collection of the laws then applicable was made to supply this deficiency. In 876 the emperor Basil I. ordered an abridgment of the Roman and Greek law to be prepared for use as a text book. He afterward appointed a committee of jurists to make a compilation of the practical law in the Greek language, and for this purpose to reduce Justinian's law collections, and the constitutions issued by him and his successors, to a system embracing the whole. His son, Leo the Philosopher, completed and published it. This Romano-Greek code is called the *Basilica*. About 945 the emperor Constantine Porphyrogenitus undertook a new edition of the *Basilics*, which has been preserved to us.—During the anarchy of the middle ages arts and sciences declined, and so did the scientific study of the law. In the 12th century the study of the Roman law revived, especially at the law school of Bologna. Irnerius delivered lectures there, and founded the reputation of this school. He illustrated the text of Justinian's collections by brief annotations on their subjects and language, which were called glosses, and were placed in the margin at the side and partly under the text. Irnerius was followed in this manner of illustration by his pupils and successors; thence they are called glossators. The glossators also tried to facilitate the study of the law by inserting extracts from the novels of Justinian into those constitutions which were altered or modified by them. These quotations of the novels were afterward called *authentica*. Soon after the revival of the study of the Roman law in Italy by the glossators, an equal zeal for it arose in the law schools and courts of France, and since the 16th century in Spain and the Netherlands, and in Germany since the 14th century. With most of the European nations, and in the new states in Spanish America, and in Louisiana, the Roman law constitutes the principal basis of their own law. In England the Roman law has never been adopted as a general subsidiary law. In Scotland the civil law has at all times been cultivated and taught. In Germany universities were established after the 14th century on the model of those in Italy, and professors of the Roman law were appointed. The authority of the Roman law in Germany is not based on a formal reception by the legislative power, but on its gradual introduction as a law of custom since the commencement of the 13th century. In 1495, in establishing the court of the imperial chamber, its members were ordered to administer justice in accordance with the imperial and common laws; by the latter the Roman and canon laws were understood.

The Roman law forms in Germany, in some branches, the principal law, in so far as the German law does not add to or modify it. In other branches it is only supplementary, that is, it only supplies the deficiencies of the German law. Only those parts and passages of Justinian's law collections are of force which are glossed, and only those of the glossed passage are binding which contain the latest legal rule. Those precepts of the Roman law which relate to Roman manners and institutions unknown in Germany are inapplicable there, though glossed; and the Roman law does not admit of application to such objects and transactions as were unknown to the Romans, and are purely of German origin. With the restrictions above enumerated, the Roman law has been adopted as common law in a body, and not by single principles. Therefore, he who can refer to a precept of the Roman law in support of his case has, as the practitioners call it, a *fundata intentio*; that is, the presumption is in favor of the validity and applicability of the precept referred to, until his adversary proves that it is included in one of the above mentioned exceptions, or that it can no longer be applied, or that it had been abolished by later law. However, the special civil codes in several German states, as in Prussia, Austria, Baden, and Saxony, and in France the civil code of Napoleon, have in a great measure supplanted the Roman law; but these codes, again, have in a great degree been based on the principles of the Roman law.—The principal editions of the *Corpus Juris* are: I. Glossed: that published at Lyons by the brothers Senneton (5 vols. fol., 1549-'50); that of Ant. Cortius (5 vols. 4to, Paris, 1576); the *Corpus Juris Civilis Glossatum, ex recensione Dionysii Gothofredi* (6 vols. fol., Lyons, 1589, without the title, *Corpus Juris, &c.*; with the title, 1604; enlarged and improved, 1612). II. The non-glossed editions are subdivided into those which contain explanatory notes of later jurists, and those which contain only the text, with or without the various readings. The best editions with notes are: that of L. Ruscusard, *Jus Civile* (2 vols. fol., Lyons, 1560-'61; Antwerp, 1566-'67, and in 7 vols. 8vo., 1569-'70); that of Dionysius Gothofredus (4to, Lyons, 1583; Frankfort, 1587; 2d ed., improved, 2 vols. fol., 1590; 3d ed., 4 vols. fol., Geneva, 1602; 4th ed., Lyons, 2 vols. fol., 1607; 4to, Geneva, 1614, and fol., 1615); the fifth and most complete edition was edited by his son, Jacob Gothofredus (fol., Geneva, 1624); this has been frequently published since; the edition of Antonius (4to, Lyons, 1652 and 1662) deserves particular mention. One of the best and most elegant editions with notes is that of Simon van Leeuwen from the last edition of Gothofredus, containing, besides Gothofredus's notes, the annotations of many others (fol., Frankfort, 1663; 2 vols. 4to, Leipsic, 1705, 1720, and 1740). Without explanatory notes are: the Amsterdam edition,

printed by Elzevir (8vo, 1664, 1681, 1687, and 1700); editions by G. C. Gebauer and G. A. Spangenberg (Göttingen, 1776 and 1797), containing various readings and explanatory notes; Pothier, *Pandectæ Justinianæ in novum Ordinem digestæ*, &c. (3 vols. fol., Paris, 1748-'52, and 1818-'21); Schröder (Berlin, 1832). Several editions of the text and most important readings, without notes, have been published at Leipsic; among them that of Beck (2 vols., 1829-'37), and another of Kriegel brothers (1828-'37); Krüger's *Justiniani Institutiones* (1867); and Mommsen's *Digesta Justiniani* (1868). Valuable works on the history of the civil law, and on the different branches of the law, are: Hugo, *Lehrbuch der Geschichte des Römischen Rechts*, of which there is a French translation; Savigny, *Geschichte des Römischen Rechts im Mittelalter*, which has been translated into French and English; Guizot, *Histoire de la civilisation en France*; Puchta, *Institutionen* (Berlin, 1832), and his *Pandekten* (1852); Pardessus, *Mémoire sur l'origine du droit coutumier en France et sur son état jusqu'au treizième siècle* (1834); A. F. Justus Thibaut, *System des Pandektenrechts* (8th ed., 1837); Savigny, *Das heutige Römische Recht* (8 vols. and 2 vols.); *Obligationenrecht* (1840-'53); Laferrière, *Histoire du droit français* (6 vols., 1846); Giraud, *Essai sur l'histoire du droit français au moyen âge* (1846); Laferrière, *Essai sur l'histoire du droit français depuis les temps anciens jusqu'à nos jours* (2 vols., 1859); Seuffert, *Das praktische Pandektenrecht* (3 vols., 7th ed., 1860-'64), and *Das praktische gemeine Civilrecht* (3 vols., 3d ed., 1868); Vangerow, *Lehrbuch der Pandekten* (2 vols., 7th ed., 1863-'9); Keller, *Pandekten* (2d ed., by Lewis, 1866); Puchta, *Pandekten* (10th ed., by Rudorff, 1866); Arndts, *Lehrbuch der Pandekten* (6th ed., 1868); Mackeldey, *Handbuch des neuen Civilrechts*; "Gaius's Commentaries on the Roman Law, with an English translation and annotations," by Tomkins and Seniors (London, 1869); Tomkins and Jencken, "A Compendium of the Modern Roman Law, founded upon the treatises of Puchta, Von Vangerow, Arndts, F. Möhler, and the *Corpus Juris Civilis*" (London, 1870); Ortolan, *Histoire de la législation romaine et généralisation du droit* (Paris, 1870; translated into English by Prichard and Nasmith, London, 1871).

CIVILIS, **Claudius**, also called **JULIUS**, leader of the revolt of the Germanic nation of the Batavi (settled around the

mouths of the Rhine and Maas) against the Romans, A. D. 69-70, as chronicled by Tacitus. Although in the imperial service as prefect of a cohort, he was of the Batavian royal race, and had no reason to love the Romans, who had wrongfully put his brother to death and sought his own life. When the contest for the purple was going on between Vitellius and Vespasian, the partisans of the latter urged Civilis to a feigned revolt, so as to prevent the legions in Germany favorable to Vitellius from marching on Rome. Civilis determined to make the revolt a real one. Under pretext of a festival he assembled the chiefs of his nation in a sacred grove and induced them to rise against the Roman yoke. Having placed a young man named Brinno at their head as nominal leader, the Batavi and two neighboring tribes, their allies, gained some skirmishes; whereon, it being no longer possible to conceal that Civilis was the prime mover, he put himself at the head of the insurgents. Still keeping up the fiction that he was fighting for Vespasian, he attacked and destroyed all the Roman camps on the Rhine, excepting Cologne and Mentz, which he retained. As the Batavi continued in arms after Vespasian had gained the empire, Cerealis was sent against them with a powerful force. Civilis offered to make Cerealis emperor of the Gauls if he would come over to their side, but the offer was declined. A campaign followed with varying success, till finally fortune turned against the insurgents, and they were driven into the island of Batavia. Cerealis offered his adversary terms. An interview between the generals took place on a bridge, where Tacitus leaves them conversing. The subsequent history of Civilis is unknown.

CIVITÀ CASTELLANA, a fortified town of Italy, in the province and 25 m. N. of Rome, upon an elevated plateau, nearly surrounded by ravines; pop. about 3,500. The Maggiore and the Treja unite just below the town, and fall into the

Cività Castellana.

Tiber 5 m. below. The cathedral is inscribed with the date 1210. The citadel is built upon the isthmus which connects the town with the higher ground. The position is one of great military strength. It was the site of the ancient Falerii or Falerium, the walls of which are still in a state of excellent preservation, and are the best specimen of Roman fortification extant. (See **FALERII**.) The French under Macdonald here achieved a victory over the Neapolitans under Mack, Dec. 4, 1798.

CIVITÀ DI PENNE (anc. *Pinna Vestina*), a town of Italy, in the province of Teramo, situated at the foot of the Apennines, 14 m. W. of Pescara; pop. about 5,000. It was the chief city of the Vestini, and distinguished for the constancy with which it remained faithful to Rome, and resisted the overtures of the Italian allies in the social war.

CIVITÀ VECCHIA, a seaport town of Italy, on the Mediterranean, in the province and 37 m. N. W. of Rome, with which it is connected by railway; pop. about 10,000. The harbor consists of two marble piers fronted by a break-

water. The water is from 14 to 18 ft. in depth. Upon the breakwater are a lighthouse, a quarantine, docks, and a prison capable of containing 1,200 persons. The town is well built, and contains several fine churches, some monuments, and a small gallery of Etruscan antiquities. It is supplied with water by a remarkable aqueduct, constructed upon the foundations of one built by Trajan. It is the best port of central Italy on the Mediterranean, and is a stopping place for lines of steamers between Marseilles, Naples, Malta, and the Levant. Travellers going to Rome generally land here. It was founded by Trajan, who constructed its port, which was called *Portus Trajani*, and was one of his most remarkable works. It was destroyed by the Saracens early in the 9th century, but was rebuilt by Pope Leo IV. The fortress was commenced under Julius II., after designs by Michel Angelo, and completed under Paul III. The moles, quays, and fortifications were built upon the ancient foundations. Clement XII. made it a free port. Its privileges were taken away in 1850, but restored in 1855.

Cività Vecchia.

CLACKMANNANSHIRE, an E. and the smallest county of Scotland, bounded S. and S. W. by the river Forth; area, 46 sq. m.; pop. in 1871, 23,742. Its N. part is occupied by the Ochil hills, between which and the rich alluvial valley of the Forth the surface is somewhat diversified, though its general aspect is level. The Devon and the Black Devon, also called the North and South Devon, are the only considerable streams. Agriculture is in a very flourishing state. Coal is largely produced, and there are many other minerals. The chief manufactures are of woollen shawls, plaids, and blankets. There are several large breweries and distilleries, glass works, brick works, potteries, and a number of iron works. Alloa and Clackmannan, the county seat, are the principal towns. Communication is afforded by the Scottish Central, the Edinburgh and Glasgow, and the Stirling and Dunfermline railways.

CLAIBORNE. I. A S. W. county of Mississippi; area, 740 sq. m.; pop. in 1870, 13,386, of whom 9,996 were colored. The Mississippi river on the west separates it from Louisiana, and the Big Black river touches its N. W. bor-

der. The surface is uneven, but the soil is generally fertile. The chief productions in 1870 were 179,187 bushels of Indian corn, 10,206 of Irish and 18,330 of sweet potatoes, 193 tons of hay, and 14,776 bales of cotton. There were 2,006 horses, 2,048 mules and asses, 3,450 milch cows, 7,205 other cattle, 2,261 sheep, and 8,884 swine. Capital, Port Gibson. II. A N. W. parish of Louisiana, bordering on Arkansas, drained by the branches of Bayou d'Arbonne; area, about 1,200 sq. m.; pop. in 1870, 20,240, of whom 10,608 were colored. The surface is undulating, and partly covered with pine and other timber. The soil is good, though not of remarkable fertility. The chief productions in 1870 were 5,961 bushels of wheat, 475,374 of Indian corn, 95,914 of sweet potatoes, 15,389 lbs. of wool, and 14,900 bales of cotton. There were 1,863 horses, 2,226 mules and asses, 4,144 milch cows, 8,012 other cattle, 8,195 sheep, and 26,952 swine. There were 4 grist mills, 6 saw mills, one cotton and one woollen factory. Capital, Homer. III. A N. E. county of Tennessee, intersected by Powell's river, and bordering on Kentucky, touching Virginia on the N. E. corner, and

bounded S. by Clinch river; area, about 350 sq. m.; pop. in 1870, 9,321, of whom 758 were colored. The surface is hilly, and in some places mountainous. It possesses a fertile soil, and has mines of lead, zinc, and iron, the last of which are very extensive and profitably worked. The chief productions in 1870 were 33,901 bushels of wheat, 204,840 of Indian corn, 59,039 of oats, and 11,301 of potatoes. There were 1,752 horses, 2,112 milch cows, 3,613 other cattle, 9,730 sheep, and 11,942 swine. Capital, Tazewell.

CLAIRAUT, Alexis Claude, a French mathematician, born in Paris, May 7, 1713, died there, May 17, 1765. At the age of 13 he read before the French academy a memoir upon four curves of his own discovery; at 16 he had written a treatise upon curves of double curvature; and at 18 he was admitted into the academy of sciences. His maturer powers were employed in researches upon the figure of the earth, in which he demonstrated the theorem that the variation of gravity on the surface of the earth, considered as an elliptic spheroid, is altogether independent of the law of density, and may be deduced from a knowledge of the form of the exterior surface; on the theory of the moon; and on the orbit of Halley's comet. In each of these subjects he showed wonderful powers, and gained the most distinguished honor. He published numerous scientific works.

CLAIRFAIT. See CLEFFAYT.

CLAIRON, Claire Joséphe Hippolyte Leyris de Latude, a French actress, born in Flanders in 1723, died in Paris, Jan. 18, 1803. She was not 13 years old when she appeared with great success at a Parisian theatre. She afterward became an opera singer, and finally was admitted in 1743 to the Théâtre Français, where she first played the part of Phèdre. She greatly contributed to the success of several of Voltaire's tragedies; she paid a visit to the old poet at Ferney, and performed in his private theatre. Having declined to play in the *Siège de Calais* with a comedian guilty of an act of dishonesty, she was thrown into prison; and sufficient amends for such treatment having been denied her, she refused to reappear on the stage. She was then but 42 years of age, and her talent had reached its zenith. Her coquetry gave occasion for the publication of a scandalous pamphlet called *Histoire de Frétillon*. When 50 years old she became the favorite of the margrave of Anspach, at whose court she resided for nearly 18 years. In 1791, on being supplanted by Lady Craven, she returned to Paris, and published there in 1799 her *Mémoires*, which derive interest from their remarks on dramatic art. She died poor.

CLAIRVAUX, a village of France, in the department of Aube, on the left bank of the river Aube, 30 m. S. E. of Troyes; pop. about 2,000. It was the seat of a celebrated monastery dependent on the abbey of Cîteaux, founded in 1114, in a wild glen, by Hugues,

count of Champagne, and having St. Bernard as its first abbot. The foundation was increased by Thibaut, count of Champagne, and rich gifts were added by many kings of France, counts of Flanders, and other noble benefactors. The monks followed a rule of life which still further swelled their revenues. Timber was felled, saw mills were erected, the lands were drained and irrigated, farms were carefully tilled, tan yards, forges, oil mills, grain mills, fulling mills, and various hydraulic works were put in operation, cloth was woven, wool was spun, and the products not required for the use of the abbey were sold at Châtillon-sur-Seine, Bar-sur-Aube, &c. At the same time Clairvaux was a seat of learning, and was the abode at different periods of Pope Eugenius III., 15 cardinals, and many other dignitaries. In 1153 there were 700 monks within the abbey walls, and 76 other monasteries were affiliated to this. In the 17th century it possessed nearly 50 villages, a vast number of farms, large vineyards, 60,000 acres of forest, 1,500 acres of fallow land, 4 metal forges and founderies, and an income of \$120,000 a year; the number of its affiliated houses was 537, while the circuit of its walls exceeded that of the neighboring town of Chaumont. Its vast buildings have been converted into a prison (*maison centrale de détention*), where the convicts are employed in several trades, the proceeds of which defray the expenses of the establishment. It is one of the best regulated prisons in France. The abbey church, which contained the tombs of St. Bernard and of several kings and princes, was torn down to make room for the prison yard.

CLAJUS. I. Johann, a German clergyman and author, whose real name was CLAI, born at Herzberg, electoral Saxony, about 1533, died at Bendeleben, Thuringia, April 11, 1592. He studied at Grimma and Wittenberg, and became a teacher of music, poetry, and Greek at Goldberg. After returning to Wittenberg to qualify himself for the ministry, he was installed in 1572 as rector at Nordhausen, and in 1574 at Bendeleben. He acquired eminence by his erudition, by his German and Latin poems, by his German, Latin, Greek, and Hebrew editions of Luther's minor catechism, and especially by his *Grammatica Germanica Lingua* (Leipsic, 1578), which was one of the earliest and most thorough works of the kind. **II. Johann**, a German clergyman and poet, born in Meissen in 1616, died at Kitzingen in 1656. He studied theology at Wittenberg, and in 1647 became a teacher at Nuremberg, and in 1650 a preacher at Kitzingen. He was one of the leaders of the Nuremberg school of poetry, and with Harsdorfer founded the poetical union known as the *Pegnitzorden*. He published the *Pegnesisches Schäfergedicht* (Nuremberg, 1644), and several of his *Geistliche Trauer- und Freudenstücke* continue to be popular.

CLALLAM, a N. W. county of Washington territory, bounded N. by the strait of Juan

de Fuca; area, 1,720 sq. m.; pop. in 1870, 408. It is watered by several streams that fall into the strait. Mount Olympus, 8,138 ft. high, the N. peak of the Olympic range, is in this county. The soil is fertile. The chief productions in 1870 were 8,636 bushels of wheat, 4,435 of oats, 3,460 of barley, 33,782 of potatoes, 1,086 tons of hay, and 19,767 lbs. of butter. The value of live stock was \$64,552. Capital, New Dungeness.

CLALLAMS, a tribe of Indians on the N. W. coast of North America, who call themselves Nuskliyum. They inhabit the shores of the Straits of Fuca from the Okeho river to Port Townsend, bounded by the Makahs or Classets on the west and the Chemakung on the east, and live by hunting and fishing in the rivers and bays, their canoes not being fit for the sea. About 600 were scattered along the shore for about 100 miles in 1870, but they were diminishing very rapidly. A few of them, by the treaty of Point no Point, Jan. 26, 1855, were established on the Skokomish reservation in Washington territory, but not many have actually ever settled there. The Clallam language is a dialect of the Selish, but differs materially from others of the same stock.

CLAM, a common name for several species of bivalve shells. The largest of these, the giant clam, the *tridacna gigas* of Lamarck, but formerly classed in the genus *chama*, is an edible species found among the sheltered lagoons of coral islands, and imbedded in the coral; the animal sometimes weighs 20 lbs., and with the valves over 500 lbs. Such are the valves of the specimen used for *bénitiers* in the church of St. Sulpice, Paris. Sir Joseph Banks possessed one which weighed, one valve 285, and the other 222 lbs. The shell is susceptible of a fine polish, and is carved by the Chinese into snuff bottles, tops of walking sticks, and similar articles. Poets and sculp-

Giant Clam (*Tridacna gigas*).

tors have made it the cradle of the sea goddess. The common soft clam of the northern shores is the *mya arenaria*; the hard clam or quahaug is the *venus mercenaria*; and the broad sea clam is the *mastragigantea*. The unios, anodonts, &c., of the brooks and rivers are

often called fresh-water clams. The *mya arenaria*, by its abundance on the coast of New England, is of importance as an article of food, and is also largely used for bait in cod and haddock fishing. They frequent soft bottoms, especially the gravelly mud of river

Soft Clam (*Mya arenaria*) and Quahaug (*Venus mercenaria*).

mouths, and are most abundant between low water and half-tide mark. The siphon is neither head nor tail, but a double retractile tube for respiratory and feeding purposes; mantle open at the opposite end, nearest the mouth, for the extrusion of the foot, by which they burrow in the mud with considerable rapidity; the shells are generally very hard, light-colored or sandy, and almost black on muddy bottoms. With the exception of the soft mass usually called the belly, they are, especially when cooked, rather indigestible. The shells are dug up from their beds, which are exposed at low water, where they are found lying about a foot below the surface, their siphon tube projecting upward in the hole by which they communicate with the water at high tide. They are taken out of the shells, or "shucked," and salted down in barrels. About 5,000 barrels are put up every year for the fisheries, and are valued at from \$6 to \$7 each. In the early history of the Plymouth colony clams were several times the principal source of sustenance for the people.

CLAMECY, a town of France, in the department of Nièvre, situated at the foot of a hill at the confluence of the Yonne and the Beuvron, 38 m. N. E. of Nevers; pop. in 1866, 5,616. The parish church is a handsome building of the end of the 15th century, with a remarkable tower and fine statuary; and the château de Vauvert is surrounded by delightful pleasure grounds. On the bridge over the Yonne is a bronze bust of a native of Clamecy, Jean Rouvet, who introduced the manufacture of wood rafts for the supply of Paris with fire wood, which are floated down the Yonne and Seine. The suburb across the former river is called Bethlehem, in honor of a bishop who was expelled from that city after its capture by the Saracens, and who, accompanying the count de Nevers to Clamecy, was endowed with the suburb and with a see which existed

till the revolution of 1789. Cloth, stationery, earthenware, and other articles are manufactured, and there are dye works, fulling mills, potteries, and many tanneries. It was formerly surrounded by stupendous walls and defended by a castle, and previous to the revolution held a prominent position in the duchy of Nevers.

CLANWILLIAM, a N. W. district of Cape Colony, S. Africa, partly traversed by the Roggeveld and other mountains, and by the Olifant river and its tributaries; area, 24,100 sq. m.; pop. in 1865, 7,041. The climate is salubrious and the soil fertile. The capital of the district is a village of the same name, 140 m. N. E. of Cape Town, whose people are chiefly employed in manufacturing hats. In the vicinity is an excellent chalybeate spring.

CLAP, Thomas, an American clergyman, born at Scituate, Mass., June 26, 1703, died in New Haven, Jan. 7, 1767. He was settled as a minister at Windham, Conn., in 1727, and in 1739 was elected president of Yale college, which office he held till 1766. He contributed much to improve Yale college, and was the means of building a college edifice and chapel. He was a man of extensive erudition, gave great attention to mathematics and astronomy, and constructed the first orrery made in this country. He published the history of Yale college, and other writings, and had made collections for a history of Connecticut; but most of his manuscripts were plundered in the expedition against New Haven under Gen. Tryon. He had a controversy with President Edwards respecting Whitefield, and opposed the latter, not so much upon religious grounds as from a misapprehension of Whitefield's designs.

CLAPARÈDE, Édouard, a Swiss naturalist, born in 1832, died in 1871. He studied medicine and the natural sciences, and became professor of comparative anatomy at the academy of Geneva. His works include *De la formation et de la fécondation des œufs chez les vers nématodes* (Geneva, 1858); *Études sur les infusoires et les rhizopodes* (2 vols., 1858-'60); *Recherches anatomiques sur les annélides turbellariés, opalines et grégarines, observés dans les Hébrides* (1861); *Sur les oligochètes* (1862); *Recherches sur l'évolution des araignées* (1862); *Études sur la circulation du sang chez les aranéides du genre lycose* (1863); and *Glanures zootomiques parmi les annélides de Port-Vendres* (1864).

CLAPISSON, Louis, a French composer, born in Naples, Sept. 15, 1808, died in Paris, March 19, 1866. He was the son of a French musician established at Naples, and was educated in Paris. In 1854 he was appointed professor of music at the conservatory, and in 1861 director of a museum which he had founded and presented to the government, for the preservation of musical relics and instruments. He was distinguished as a composer of ballads, songs, and comic operas. Among his most successful operas are *La perruche* (1840), *Le*

code noir (1842), *Gibby, la cornemuse* (1846), *La fanchonette* (1856), and *Margot* (1857). His latest works were *Les trois Nicolas* (1858), and *Madame Grégoire* (1861).

CLAPP, Theodore, an American clergyman, born in Easthampton, Mass., March 29, 1792, died in Louisville, Ky., April 17, 1866. He graduated at Yale college in 1814, studied theology at Andover, and in 1822 became pastor of the first Presbyterian church in New Orleans. In 1834 he adopted Unitarian views and dissolved his connection with the Presbyterian church, but remained pastor of nearly the same congregation as before, organized under the name of the church of the Messiah. He resided in New Orleans through 20 epidemics, including yellow fever and cholera, during which he earned universal esteem by his laborious devotion to all classes of citizens. In 1847 he travelled in Europe; in 1857 he resigned his pastorate on account of ill health; and in 1858 he published a volume of "Autobiographical Sketches and Recollections" of a 35 years' residence in New Orleans.

CLAPPERTON, Hugh, a traveller in Africa, born at Annan, Scotland, in 1788, died near Sackatoo, Africa, April 13, 1827. At the age of 13 he was apprenticed to a shipmaster trading between Liverpool and New York, with whom he made a number of voyages. For an accidental violation of the excise laws he was sent on board a man-of-war, and speedily reached the rank of midshipman. He served on the American lakes during the war of 1812-'15, became lieutenant, and was placed in command of a schooner. He returned to Scotland in 1817, and remained on half pay till 1822, when he joined Dr. Oudney's expedition for the exploration of the interior of Africa. The expedition started from Moorzook, Nov. 29, 1822, and reached Lake Tchad, in the kingdom of Bornoo, Feb. 4, 1823. The distance was 800 m. Six days after entering Kuka, the capital, Clapperton and Oudney set out for Sackatoo, the capital of Houssa, more than 700 m. W. of Kuka. The journey was long and disastrous, occupying 90 days, and accompanied by many privations. When they had accomplished about a third of the distance Oudney died; and Clapperton, having reached his destination, was not suffered to proceed further westward, and after a short stay returned to Kuka, whence he proceeded in company with Major Denham to Tripoli, and thence to England. Within six months after his return he was raised to the rank of captain, equipped with the necessary men and goods for trading, and sailed for Badagry in the bight of Benin. Arriving there Dec. 7, 1825, he journeyed N. E. toward Sackatoo. Two of his companions, Capt. Pearce and Dr. Morrison, fell victims to the fatal climate within a short distance of the coast; still Clapperton, accompanied by his faithful servant Richard Lander, pressed on. At Katunga they approached the Joliba, the western and main branch of the Niger, and

crossed it without knowing that it was the stream of which they were in search. Proceeding north, they reached Kano, a considerable town, from which proceeding west they arrived again at Sackatoo. Here he was detained for more than a year by the jealousy of the native king and the intrigues of the pasha of Tripoli, until he fell a victim to dysentery. (See LANDEE.)

CLARAC, Charles Othon Frédéric Jean Baptiste, count, a French antiquary and artist, born in Paris, June 16, 1777, died in 1847. Having emigrated with his family, he served for some time in the army of the prince of Condé, and afterward entered a Russian regiment; but his leisure hours were devoted to the study of natural philosophy and the fine arts. Availing himself of the amnesty granted under the consulate, he returned to France, and being chosen tutor to the children of King Murat, he repaired to Naples in 1808. During his stay there he superintended the excavations at Pompeii, the results of which he described in his *Fouilles faites à Pompéi*. After the downfall of Murat he returned to France, and soon afterward went with the French embassy to Brazil. On his return to Paris he was appointed successor to Visconti as keeper of the museum of antiquities of the Louvre. He published a catalogue of the museum, and a *Manuel de l'histoire de l'art chez les anciens* (3 vols. 12mo, 1830-'47); but his best work is the *Musée de sculpture antique et moderne* (6 vols. large 8vo, with a folio atlas, 1825-'52), completed after his death, to which he devoted his fortune.

CLARE, a central county of the southern peninsula of Michigan, drained by Maskegon and Assemoqua rivers and their branches; area, about 650 sq. m.; pop. in 1870, 366. The surface is mostly covered with forests, and diversified with small lakes. The western division of the Flint and Père Marquette railroad is to touch the S. part. The estimated value of farm productions in 1870 was \$8,808; of live stock, \$3,035. Capital, Farwell.

CLARE, a county in the west of Ireland, province of Munster, bordering on the Atlantic and the counties Galway, Tipperary, Limerick, and Kerry; area, 1,294 sq. m.; pop. in 1871, 147,994, of whom 144,589 were Catholics. It has an extensive coast line, and is rich in natural resources. Its mineral deposits are numerous—ironstone, coal, iron ore, lead, copper pyrites, manganese, black marble, slate and flag quarries, lime, and sand. Although deficient in water, and with a rugged surface, there is abundance of pasturage among the hills; while on the banks of the Shannon, which forms its southern boundary, and other spots, in which surface waters occasionally collect, there is much fine soil. Corn and provisions are the staple products, and coarse linens and woollens are made for home use. Among the numerous ancient remains of the county are round towers, the abbey built by Turlough O'Brien in 1306 at Ennis, and the abbey of

Quin, built of black marble, in the 13th century. Capital, Ennis.

CLARE, John, an English poet, born at Helpstone, July 13, 1793, died at Northampton, May 19, 1864. He was the son of a poor farmer, and enjoyed very few advantages of early education. He began to write verses at the age of 13, but it was not till 1818 that he attracted public attention by the publication of his "Collection of Original Trifles." This led to the publication in 1820 of a volume of poems, with a brief biographical introduction, and bearing the title of "Poems Descriptive of Rural Life and Scenery, by John Clare, a Northamptonshire Peasant," which was received with general favor by the public and the reviews. In a short time numerous gifts of from £10 to £100 were bestowed upon him, and finally an annuity of £45. He married the daughter of a neighboring farmer, whom he had celebrated in several small poems. He published in 1821 "The Village Minstrel and other Poems," which was followed by the "Shepherd's Calendar and other Poems," and the "Rural Muse," which appeared in 1836. These contained some poems of rare beauty. He often described with peculiar force the impression made upon the mind by the sight of lovely objects in nature. His prosperity did not continue long after this. He fell into pecuniary embarrassment, and amid increasing difficulties sank into a state of despair and mild lunacy. He was for many years in a private asylum at Northampton.—See "Life and Remains of John Clare," by J. L. Cherry (London, 1873).

CLAREMONT, a town of Sullivan co., N. H., on the Connecticut river, 48 m. W. by N. of Concord; pop. in 1870, 4,053. The Vermont Central and the Concord, Claremont, and Contoocook railroads pass through it. There is good water power at this point, and the town contains three cotton and two woolen mills, a national bank with a capital of \$150,000, several churches, and three weekly newspapers. The Stevens high school in 1871 had 4 teachers and 85 students. Paron Stevens of New York bequeathed \$50,000 to this institution in 1872.

CLAREMONT, a palace near Windsor, England, assigned in 1816 to the princess Charlotte, on her marriage with Prince Leopold of Saxe-Coburg, who after her death in 1817 remained in possession of it, residing there till his accession to the Belgian throne, July 21, 1831. In February, 1848, he placed it at the disposal of Louis Philippe, who resided there with his family till his death in 1850, and his widow, Marie Amélie, died there in 1866. After the death of Leopold in 1865, the palace became again the property of the English crown.

CLARENDON, an E. central county of South Carolina, bounded N. E. by Lynch's creek, S. W. by the Santee river, and intersected by Black river and its tributaries; area, 700 sq. m.; pop. in 1870, 14,038, of whom 9,366 were

colored. The surface is diversified; part of the soil is fertile. The chief productions in 1870 were 218,417 bushels of Indian corn, 24,635 of peas and beans, 75,330 of sweet potatoes, 5,016 bales of cotton, and 813,012 lbs. of rice. There were 996 horses, 3,314 milch cows, 5,256 other cattle, 1,523 sheep, and 14,986 swine. Capital, Manning.

CLARENDON, Edward Hyde, earl of, a British statesman and historian, born at Dinton, Wiltshire, Feb. 18, 1608, died in Rouen, France, Dec. 9, 1674. His family belonged to the English gentry, and had for several centuries been settled in Cheshire. He was educated at Magdalen hall, Oxford (1621-'6), and had been intended for the church; but his destination was changed in consequence of the death of his elder brother, and he was entered in the Middle Temple, of which his uncle, Sir N. Hyde, was treasurer. His studies were more miscellaneous than legal, and he associated much with loose characters. He did not show application until after his marriage in 1629 with Anne Ayliffe, who died six months afterward. In 1632 he married Frances Aylesbury. The deaths of his father and uncle had a grave effect on his character, and he applied himself to professional labors, yet not neglecting literature or politics. Circumstances of a professional nature brought him the acquaintance of Archbishop Laud, then the most powerful member of the government, by whom he was much assisted, and whom he greatly assisted in return. Being chosen a member of the short parliament, which met April 13, 1640, he took the government side, though moderately, and was brought into collision with Hampden. On May 5 the parliament was dissolved by the king, a measure to which Hyde was opposed, boldly remonstrating with Laud on the subject. He was an advocate of practical reforms, and had the policy which he indicated been pursued, there can be little doubt that the British throne would have remained in possession of the house of Stuart. Hyde was chosen by Saltash to serve in the long parliament, November, 1640. In the first proceedings of that celebrated body he was as conspicuous a reformer as either Pym or Hampden. He led the way in the abolition of some of those arbitrary tribunals by the use of which the Stuarts were seeking to make of England a monarchy after the fashion of France, the earl marshal's court and the council of York especially. He took part in the proceedings against the judges who had been concerned in the ship-money business, and in the impeachment of Lord Keeper Finch, distinguishing himself particularly in the latter transaction. He was not so prominently concerned in the proceedings against Strafford, but yet was active in them. In the summer of 1641 Hyde separated himself from the reformers, indications of his intention to do so having been afforded at an earlier date. He broke with them on church questions, and his decision was apparently hastened by his dis-

covery of the republican leanings of some of their chiefs. He attracted the king's attention, and they had an interview just before Charles made a visit to Scotland. From that time dates his connection with the Stuarts. He was one of those who, although opposed to arbitrary power, believed the parliament had gone far enough. The house of commons was beginning to evince an arbitrary disposition on some points, while the utter faithlessness of the king was unknown to the world. A reaction had commenced, but Charles knew not how to profit by it. The Irish rebellion and other circumstances were sufficient to set the popular tide in favor of the parliament again, when the bringing forward of the "grand remonstrance," in which all the king's crimes and errors were clearly set forth, led to a close contest in parliament, the result of which showed that the reformers were carrying matters too far, as they triumphed by only 11 majority. Hyde was very conspicuous in opposition, and narrowly escaped being sent to the tower. The king's answer to the remonstrance was written by Hyde, and is an able state paper. Sensible of Hyde's talents, the king determined to associate him with Falkland and Colepeper as his chief ministers and advisers. He refused to accept office, but the three constitutional royalists were to meet often, to consult on the king's affairs, and to conduct them in parliament, the monarch asking their advice, and solemnly pledging himself to take no step in parliament without that advice; a pledge which he kept after his usual fashion. All three were of service to him, meeting every night, generally at Hyde's house, he doing all the writing that was necessary, and corresponding with the king. The suspicions of the other party were directed to him, but this could not have proved injurious if the king had acted with common honesty. In violation of his pledge to Hyde and his associates, as well as in violation of law, he endeavored to seize the "five members," an act that not only made civil war inevitable, but set the country once more against the king. Hyde says they were absolute strangers to the royal counsels, and detested them. Still he remained the royal adviser, and aided the king with his pen. He opposed the bill to remove the bishops from the house of peers. In the dispute between the king and parliament respecting the militia, Hyde was the author of the ablest royal papers, all written in a constitutional spirit. The king had left London, and he summoned Hyde to York, to the vicinity of which he went in May, 1642. The war began three months later, but negotiations were commenced for an accommodation, and Hyde's services were put in requisition. In 1643 he was made chancellor of the exchequer, knighted, and sworn of the privy council. On the death of Falkland the king offered to make him secretary of state, but he declined the appointment. It was by his advice that parliament was summoned to

meet at Oxford, where large numbers of both houses assembled. He was one of the royal commissioners who met the parliamentary commissioners at Uxbridge, the burden of the work on the royal side falling on his shoulders. The negotiations failed. When the king appointed Prince Charles head of the western association, Hyde was made a member of the prince's council, and saw the king for the last time March 5, 1645. During the proceedings in the west he attended the prince, first to Scilly, and then to Jersey. In the latter island he remained over two years, and long after the prince had left it. In his correspondence he condemned the king's duplicity, as proved by the circumstances of Glamorgan's treaty. He commenced his "History of the Rebellion" while at Scilly, in March, 1646, and labored very diligently on it in Jersey. In the summer of 1648 he joined Prince Charles in Holland, and had some part in the intrigues of his quarrelsome court. The next year he was sent minister to Spain, in company with Lord Cottington. His mission proved a failure, and he left that country in 1651, taking up his residence at Antwerp. At the close of the year he joined Charles II. at Paris, and was intrusted with the management of his affairs. This brought him much unpopularity, and the exiled court was the scene of the worst intrigues. He suffered the extremes of poverty, and speaks in his correspondence of his lack of money, clothes, and fuel. The queen mother was his bitter enemy, and sought with the aid of the courtiers to ruin him, but without success. He was concerned in the plots against Cromwell's government, and listened to projects for the protector's assassination. He accompanied the vagrant court in all its wanderings, and was made lord chancellor in 1657. When it became apparent that a restoration was approaching, he favored moderate counsels. Two days after the entrance of the king into London, Hyde took the seat of speaker of the house of lords, and sat in the court of chancery. It was vainly attempted to exclude him from power, and he became head of the administration. He was made Baron Hyde, Viscount Cornbury, and earl of Clarendon, but refused the garter. He wished to keep faith with the roundheads, but the current ran too strongly against all who had opposed the royal power for even the king to maintain his faith. Clarendon sought to govern constitutionally, but in the spirit of a departed age. He offended the country party by his arbitrary ideas, and the court by the purity of his morals. His position in the government made him responsible for acts which he did not approve; and the sale of Dunkirk to the French caused him much unpopularity, the people derisively applying the name of Dunkirk house to the magnificent mansion which he had built in London. His taste led him to form a splendid gallery of paintings, many of which he was accused of extorting from neces-

sitous royalists. The marriage of his daughter Anne with the duke of York, heir presumptive to the crown, offended the nobility, and laid him open to grave suspicions with the ignorant portion of the people. Without being corrupt, he was greedy of money, which he expended in the most ostentatious manner. By the year 1667 his unpopularity was at its height. The people changed the name of his palace to Holland house, because of their suspicion that he had been bribed by the Dutch; and from that to Tangier hall, as he was charged with having taken money to assent to the holding of that African town, which was a part of the dower of Catharine of Braganza, queen of Charles II. The disasters of the Dutch war were laid to his charge, though he had been opposed to the contest. The great plague, the great fire, and "hard times" generally, tended to swell his unpopularity. The populace broke his windows, cut down his trees, and painted a gibbet on the gate of his house. He was hated for his virtues by the king and his mistresses; by the cavaliers, because he had upheld the act of indemnity; by the dissenters, because he had promoted the act of uniformity; and by the Catholics, because he had opposed the dispensing power. The house of lords were offended by his showing regard for the constitutional privileges of the commons; and the house of commons believed he was either opposed to the very existence of parliaments, or had advised the dissolution of the parliament then existing. The king, who always disliked extremes, recommended him to surrender the great seal; advice which he refused to take, framing his reply in language which could not fail to be offensive. Four days later (Aug. 13, 1667) he was forced to surrender the seal; but this did not satisfy his enemies, who on the meeting of parliament proceeded to extremities against him, encouraged by a reflection on him that appeared in the king's speech. It was then proposed to proceed against him by impeachment generally, but the lords refused to arrest him unless some specific charge were made. Finally, Clarendon was induced to retire to France, whereupon parliament passed a bill of banishment, and his vindication was burned by the hangman. At Evreux he was assailed by a mob of English sailors, and came near being murdered. He resided at Montpellier, Moulins, and Rouen for seven years. His retirement was devoted to literary pursuits. He completed his "History of the Rebellion," finished a work on the Psalms which he had commenced when in his first exile, wrote his "Life," an answer to Hobbes's "Leviathan," a large number of essays on political, moral, and religious subjects, a "Discourse on the Papal Power," &c. His collected writings would form almost a library, and they would show an extensive range of subjects. His "History of the Rebellion" is one of the most remarkable works in the literature of modern times. It is full of errors

of omission and commission, deliberately made. Indeed, Clarendon wrote an "apology" or "vindication" of the royal party, and not a history of the contest between that party and their opponents. Yet it has become a classic; and, to use the language of the author's descendant and biographer, "the arrangement of its materials, the dignity of its tone, the happy combination of disquisition with description, the felicity of expression which it frequently displays, the development of motives, the discrimination of character, have received the warm and merited admiration of many generations of readers."—Two of Clarendon's granddaughters, Mary and Anne, became queens regnant of England. Clarendon's "Life and Administration" has been written by T. H. Lister, one of his descendants. His "Life," and other autobiographical writings, are not to be trusted, and are inferior in value and interest to the "History of the Rebellion." It was not until more than 150 years after his death that his "History" and "Life" were published in a perfect state, for which we are indebted to the learned Dr. Bandinel.

CLARENDON, George William Frederick Villiers, fourth earl of, and Baron Hyde of Hindon, a British statesman, a descendant of the preceding through the female line, born in London, Jan. 12, 1800, died there, June 27, 1870. His earliest appointment was as commissioner of customs in Ireland. In 1833 he was appointed by Lord Grey's government envoy extraordinary and minister plenipotentiary to Spain. He filled this post, at that time one of importance and difficulty, in a manner highly creditable to himself and acceptable to the constitutional party in Spain, which was in a state of anarchy and civil war during the first years of his mission. The success with which Mr. Villiers had conducted the negotiation of a treaty for the effectual suppression of the slave trade, and the manner in which he had performed his other official duties, were warmly eulogized by Lord Palmerston in his speech on the foreign affairs of the country in April, 1837. On the decease of his uncle, the third earl, he succeeded to the peerage, Dec. 20, 1838, and returning to England in 1839 took his seat in the house of lords. He was soon called to vindicate the policy of the ministry by which he had been employed, and his own conduct as their representative in Spain, against the attacks of the marquis of Londonderry, a champion of the Carlist faction. His defence of the Spanish character and the policy of the constitutional party in Spain was so acceptable in that country, that a gold medal was struck in his honor. In 1839 Lord Clarendon became a member of the Melbourne government as lord privy seal, and in 1840 he was made chancellor of the duchy of Lancaster. He retired from the ministry on Sir Robert Peel's accession to power in 1841, but supported all the liberal measures of his government. When the repeal of the corn laws was brought forward in 1846,

Clarendon made an able speech in its support. On the change of administration, and the accession of Lord John Russell to power in 1846, Clarendon was appointed president of the board of trade, which office he filled until the death of the earl of Bessborough, May 16, 1847, who had been appointed lord lieutenant of Ireland under the same administration, when he was transferred to that office. He was at first extremely popular. His situation, however, soon became one of embarrassment. The distress produced by the famine was severe, and the measures for its mitigation adopted by the imperial parliament were attended with very limited success. Nothing within the power of the executive was neglected by Clarendon. The short-lived rebellion of Smith O'Brien followed. It was subdued with the smallest possible amount of bloodshed; but Clarendon's popularity with both parties was impaired. The disaffected looked upon him with aversion as the agent of an odious government, and the Orange faction were disgusted with his mildness. He experienced the too common fate of moderate counsels, in alienating both extremes of party. His conduct was not only unpopular with both factions in Ireland, but was severely denounced by Lord Stanley (afterward earl of Derby) in the house of lords. Clarendon on this occasion left his government in Ireland, and, appearing in his seat in parliament, vindicated his conduct. On the formation of the first Derby ministry in 1852, Clarendon was superseded by Lord Eglinton in the government of Ireland. Under Lord Aberdeen's premiership, the department of foreign affairs, after it was resigned by Lord John Russell, was intrusted to Lord Clarendon (1853), and was conducted by him with acknowledged ability. Of all Aberdeen's ministry, he retained perhaps the greatest share of the public favor, and remained in office on Lord Palmerston's accession to power. The important negotiations relative to the Crimean war and the adjustment of the balance of Europe at its close were carried on by Lord Clarendon with marked though not ostentatious vigor, and in a conciliatory spirit. He signed the treaty of alliance between Great Britain and France, April 10, 1854; remained at his post during the ministerial crisis of February, 1855; had an interview with Napoleon III. at Boulogne (March 3) on occasion of the death of the emperor Nicholas; took a prominent part in the peace conference at Paris, when he came forward as a champion of the liberal institutions of Belgium, and signed the treaties of Paris of March 30 and April 15, 1855. He was less fortunate in conducting the relations of England with the United States. The negotiations relative to Central America and the enlistment question produced a temporary coldness toward the government of the United States, and the dismissal of Mr. Crampton, the British minister at Washington. Clarendon continued to administer the foreign office till the earl of Derby

effected his return to power in 1858, when he was succeeded by the earl of Malmesbury. In 1861 he was named ambassador extraordinary to attend the coronation of King William of Prussia. In March, 1864, he rejoined Palmerston's cabinet as chancellor of the duchy of Lancaster. He afterward entered upon a private mission to the emperor Napoleon at Vichy, and as joint plenipotentiary represented England at the conference of London having for its object the cessation of hostilities between Germany and Denmark on the Schleswig-Holstein question. In November, 1865, Lord Russell having succeeded Lord Palmerston as prime minister, Clarendon again became secretary of state for foreign affairs, and continued in that office until the formation of a new government by Lord Derby in July, 1866. In the beginning of 1868 he acted as an envoy to the pope and King Victor Emanuel of Italy, to prevent if possible the impending conflict, and announced that in case of war England would maintain a friendly neutrality with France. On the accession of Mr. Gladstone to power in 1868, Lord Clarendon was again appointed foreign secretary, and retained the office till his death. In January, 1869, he resumed with the American minister, Reverdy Johnson, the negotiations which had been conducted by Lord Stanley in the matter of the Alabama claims, which were now concluded by the so-called "Johnson-Clarendon treaty." This treaty was advocated by Clarendon with great zeal in the house of lords, but was rejected almost unanimously by the senate of the United States.—His eldest son having died in 1846, he was succeeded in the earldom by his second son, EDWARD HYDE VILLIERS, born Feb. 11, 1846, who had previously represented in parliament the borough of Brecknock.

CLARENDON PARK, an extra-parochial liberty and anciently a royal forest of Wiltshire, England. In a royal palace or hunting seat here, some traces of which yet remain, Henry II. held the council which enacted in 1164 the celebrated constitutions of Clarendon, aiming to repress the power of the clergy. It gave the title of earl to Lord Chancellor Hyde.

CLARET. See FRANCE, WINES OF.

CLARETIE, Jules Arnaud, a French author, born in Limoges, Dec. 3, 1840. He was educated in Paris, and became a journalist and lecturer, but was forbidden to deliver public addresses in 1865 and again in 1868, and in the latter year he was also subjected to penalties for some of his publications on account of their ultra-republicanism. As a friend of Victor Noir he appeared as a witness in the trial of Prince Pierre Bonaparte at Tours in March, 1870. In the early part of the Franco-German war he followed the army as correspondent for the *Assemblée Nationale*, and after the downfall of the second empire he officiated for a time as chief of the communal libraries in the hôtel de ville. At the election of Feb. 8, 1871, he was defeated as a candidate for the national

assembly, and in February, 1872, he founded the *Corsaire* newspaper. He has written *Voyages d'un Parisien* (1865); *Mademoiselle Cachemire* (1867); *Les derniers montagnards*, a historical essay (1867); *La famille des gueux* and *Raymond Lindey*, dramas in which he had collaborators (1869); *Paris assiégé—tableaux et souvenirs* (1871); *Histoire de la guerre de 1870-1871* (2 vols., 1872); and *Le roman des soldats* (1872).

CLARI, Giovanni Carlo Maria, an Italian composer, born in Pisa in 1669, died in the first half of the 18th century. He studied under Colonna, became a chapelmaster, and composed in 1685 an opera, *Il savio delirante*, which was favorably received at Bologna. He composed and arranged church music, whence he was called Abbate Clari, and acquired celebrity by his chamber duets and trios, published in 1720.

CLARINET, a musical wind instrument of wood, played through a reed, with holes and keys for the fingers. Its compass extends from E below the F clef to about three octaves above, although its powers are not equal throughout. It is heard to best advantage in the keys of C and F, in which most of the music for it is written. Its invention is ascribed to Johann Christoph Denner, of Leipsic, who died in 1707.

CLARION, a N. W. county of Pennsylvania; area, 600 sq. m.; pop. in 1870, 26,537. It is bounded S. W. by Alleghany river, which is here navigable by steamboats, and intersected by the Clarion, from which it is named. The soil is good, and the surface either undulating or hilly. Bituminous coal, iron, and limestone are found in the county, and timber of various kinds is abundant. The Alleghany Valley railroad traverses it. The chief productions in 1870 were 152,172 bushels of wheat, 99,339 of rye, 251,183 of Indian corn, 607,290 of oats, 46,139 of buckwheat, 57,678 of potatoes, 28,104 tons of hay, 565,070 lbs. of butter, and 88,787 of wool. There were 6,718 horses, 7,877 milch cows, 10,858 other cattle, 29,844 sheep, and 12,908 swine. There were 27 saw mills, 16 boat-building establishments, 9 manufacturing of pig iron and castings, 5 of agricultural implements, 13 of carriages, 8 of saddlery and harness, 2 of woollen goods, 3 distilleries, 15 tanneries, and 13 currying establishments. Capital, Clarion.

CLARK, the name of five counties in the United States. **I.** A S. E. county of Mississippi, bordering on Alabama, watered by the Chickasawha river; area, 650 sq. m.; pop. in 1870, 7,505, of whom 3,432 were colored. The surface is somewhat hilly, and occupied partly by pasture lands. The Mobile and Ohio railroad passes through it. The chief productions in 1870 were 62,721 bushels of Indian corn, 1,929 of oats, 12,922 of sweet potatoes, 1,142 bales of cotton, and 9,609 lbs. of rice. There were 356 horses, 879 milch cows, 2,191 other cattle, 1,092 sheep, and 3,760 swine. There were 5 saw mills and 2 woollen mills. Capital,

Quitman. **II.** An E. central county of Kentucky; area, 210 sq. m.; pop. in 1870, 10,882, of whom 3,715 were colored. It is bounded S. by Kentucky and Red rivers, of which the former is navigable, and the latter furnishes good water power. The surface is hilly and broken, and much of the soil exceedingly fertile. Hydraulic limestone is the principal rock. The Elizabeth, Lexington, and Big Sandy railroad is to pass through it. The chief productions in 1870 were 38,692 bushels of wheat, 36,636 of rye, 774,210 of Indian corn, 38,810 of oats, 20,161 of potatoes, 3,495 tons of hay, 137,150 lbs. of butter, and 32,886 of wool. There were 4,046 horses, 1,897 mules and asses, 3,901 milch cows, 12,879 other cattle, 8,054 sheep, and 17,328 swine. There were 5 manufactories of carriages, 1 of cheese, 1 flour mill, 4 saw mills, and 2 distilleries. Capital, Winchester. **III.** A S. W. central county of Ohio; area, 380 sq. m.; pop. in 1870, 32,070. It is intersected by Mad river, and drained by a number of smaller streams. The surface is diversified, and the soil fertile, well watered, and plentifully supplied with timber. It is traversed by the Cincinnati, Sandusky, and Cleveland railroad and its London branch, by the Pittsburgh, Cincinnati, and St. Louis road and its Xenia and Springfield branch, by the Atlantic and Great Western, and the Springfield branch of the Cleveland, Columbus, Cincinnati, and Indianapolis railroad. The chief productions in 1870 were 600,732 bushels of wheat, 1,204,559 of Indian corn, 227,994 of oats, 94,539 of potatoes, 23,561 tons of hay, 449,334 lbs. of butter, 259,742 of wool, and 233,360 of flax. There were 6,716 horses, 5,845 milch cows, 9,130 other cattle, 54,225 sheep, and 23,410 swine. There were 11 manufactories of agricultural implements, 18 of carriages and wagons, 5 of iron castings, 7 of machinery, 2 of paints, 2 of woollen goods, 16 flour mills, 4 manufactories of boots and shoes, 9 of bricks, 1 of furniture, 5 of lime, 4 of saddlery and harness, 1 of tobacco and snuff, 2 breweries, and 4 saw mills. Capital, Springfield. **IV.** An E. county of Illinois, intersected by several streams; area, 460 sq. m.; pop. in 1870, 18,719. It borders on Indiana, and is bounded S. E. by the Wabash river, here navigable by steamboats. Stone coal is found near its banks. Alternate tracts of forest and prairie land occupy the surface, and the soil, much of which is devoted to grazing purposes, is very fertile. The St. Louis, Vandalia, Terre Haute, and Indianapolis railroad passes through the county. The chief productions in 1870 were 195,118 bushels of wheat, 614,582 of Indian corn, 212,628 of oats, 49,737 of potatoes, 18,076 tons of hay, 218,799 lbs. of butter, 69,468 of wool, and 40,126 gallons of sorghum molasses. There were 6,320 horses, 4,169 milch cows, 7,134 other cattle, 23,607 sheep, and 18,771 swine. There were 18 manufactories of carriages, 8 of furniture, 2 of woollen goods, 9 flour mills, and 6 saw mills. Capital, Marshall. **V.** A W. central county of

Wisconsin, intersected by Black river, and watered by L'Eau Claire river; area, 1,548 sq. m.; pop. in 1870, 3,450. The surface is hilly, and the soil fertile. The western division of the Milwaukee and St. Paul railroad touches the S. W. corner. The chief productions in 1870 were 12,103 bushels of wheat, 9,511 of Indian corn, 34,997 of oats, 17,317 of potatoes, and 3,846 tons of hay. The value of live stock was \$127,673. There were 10 saw mills. Capital, Neilsville.

CLARK, Abraham, an American patriot, one of the signers of the Declaration of Independence, born at Elizabethtown, N. J., Feb. 15, 1726, died at Rahway, Sept. 15, 1794. Having received an excellent education, particularly in mathematics and civil law, he chose the occupations of surveying and conveyancing. He held several important local offices under the colonial government, but upon the first appearance of resistance to the aggressions of the mother country, he took an active part in sustaining the rights of the colonists. He was a member of the committee of public safety in Elizabethtown, and on June 21, 1776, was appointed by the provincial congress one of the five delegates from New Jersey to the continental congress. In November of the same year he was reelected and served as a member of the continental congress, with the exception of the session of 1779, until November, 1783. In 1788 he again took his seat in the national legislature. He was one of the commissioners in the convention which met at Annapolis, Sept. 11, 1786, for the purpose of reporting a uniform system of commercial intercourse and regulations, for ratification by the several states; and on May 8 in the following year he was appointed one of the commissioners to represent New Jersey in the convention which framed the federal constitution. Ill health prevented his attendance at the sessions of that assembly, but in 1790 he was elected a member of the second congress, and retained his seat until a short time before his death. A monument to his memory was erected in the cemetery at Rahway, July 4, 1848.

CLARK, Alvan, an American artist and optician, born in Ashfield, Mass., March 8, 1804. A farmer's boy, his self-taught skill gained for him at the age of 22 the situation of a calico engraver at Lowell. After nine years' employment in this business at various places, he became a successful portrait painter in Boston. When over 40 years of age he became interested in telescopes, and, assisted by his sons, has been very successful in producing instruments of great accuracy. No. 9 of vol. xvii. of the "Proceedings of the Royal Astronomical Society" of London contains a list of discoveries made by him with telescopes of his own manufacture. He is also the inventor of a double eyepiece, an ingenious and valuable method of measuring small celestial arcs, from 3' to 60'. In 1863 the French academy of sciences awarded to him the Lalande prize

for discovering a new star near Sirius, by means of his own great reflecting telescope.

CLARK, Davis Waggatt, D. D., an American clergyman and author, born on the island of Mount Desert, Me., Feb. 25, 1812, died in Cincinnati, May 23, 1871. He graduated at the Wesleyan university in 1836, for seven years was president of Amenia seminary, and for nine years afterward filled important situations in the Methodist church. In 1852 he became editor of the "Ladies' Repository" and of the books issued by the western book concern, Cincinnati, and in 1864 was elected bishop. Besides preaching continually, he was a frequent contributor to the "Methodist Quarterly Review," and edited 27 volumes published by the book concern. He also published an algebra (1843), "Treatise on Mental Discipline" (1848), "Fireside Readings" (5 vols., 1854), "Life and Times of Bishop Hedding" (1854), "Man Immortal" (1864), and "Sermons" (1868).

CLARK, Sir James, a British physician, born at Cullen, Banffshire, Dec. 14, 1788, died at Bagshot Park, June 29, 1870. He studied medicine at Edinburgh, and received his degree in 1817, after which he travelled in France, Switzerland, and Italy, studying the sanitary institutions of those countries. He then settled in Rome, and practised there as a physician eight years. Returning to Edinburgh, he obtained a reputation as one of the most skilful physicians of that capital, especially in diseases of the lungs. In 1826 he settled in London, and became physician-in-chief of St. George's hospital, and consulting physician of the king, the queen of the Belgians, the duchess of Kent, and the princess Victoria. On the accession of Victoria to the throne he was chosen her physician in attendance, became physician in ordinary to the prince consort, and received the title of baronet. In 1832 he was elected a fellow of the royal society, and on the establishment of the university of London he was chosen to its senate. Dr. Clark published "Medical Notes," made during his travels (1820); "The Sanitive Influence of Climate" (1829; 5th ed., 1856), which contains a clear and philosophical account of the climates resorted to by invalids, together with meteorological tables; and a "Treatise on Pulmonary Consumption" (1835).

CLARK, Jonas, an American clergyman, born at Newton, Mass., Dec. 25, 1730, died Nov. 15, 1805. He graduated at Harvard college in 1752, and afterward officiated as pastor at Lexington, Mass. It was only a few rods from his door that the first blood was shed in the revolutionary struggle, April 19, 1775. He published a sermon on the first anniversary of the battle, 1776. He was an ardent patriot, and as a preacher was distinguished for his fervor.

CLARK, Lewis Gaylord and Willis Gaylord, American journalists, twin brothers, born at Otisco, Onondaga co., N. Y., in 1810. In 1834 Lewis became editor of the "Knickerbocker" maga-

zine, which had been founded two years before under the charge of Charles Fenno Hoffman, and continued to be its editor for about 25 years, until just before its discontinuance. During this period he wrote the "Editor's Table" and the "Gossip with Readers and Correspondents," which formed special features of the magazine. In 1852 he published "Knick-Knacks from an Editor's Table;" and in 1855 some of the contributors to the magazine issued for his benefit a volume made up from their contributions, entitled "The Knickerbocker Gallery." He died at Piermont, N. Y., Nov. 3, 1873, where he had resided many years.—Willis, his brother, died in 1841. At the age of 20 he went to Philadelphia, where he engaged in literary enterprises, and at the time of his death was proprietor and editor of the "Philadelphia Gazette." He had furnished to the "Knickerbocker" a series of contributions under the title of "Ollapodiana," which with others of his works were collected and published in 1844, and again in 1847.

CLARK, Thomas March, D. D., an American bishop, born in Newburyport, Mass., July 4, 1812. He graduated at Yale college in 1831, studied theology at Princeton, N. J., and was licensed to preach by the presbytery in 1835. He was for a time at the Old South church in Boston; but having resolved to enter the Episcopal church, he was ordained in January, 1836, and became rector of Grace church, Boston, where he remained till 1843, when he removed to Philadelphia. In 1847 he returned to Boston, and became assistant minister of Trinity church. In 1851 he became rector of Christ's church, Hartford, Conn. Having been elected bishop of Rhode Island, he was consecrated Dec. 6, 1854, in Grace church, Providence, of which church he was rector for 12 years. Besides numerous charges, addresses, &c., Bishop Clark has published works entitled "Early Discipline and Culture" (1852), and "Primary Truths of Religion" (1869). The latter has been translated into Chinese, for the use of schools in China and Japan.

CLARKE, the name of nine counties in the United States. **I.** A N. county of Virginia, bounded N. E. by West Virginia; area, 208 sq. m.; pop. in 1870, 6,670, of whom 2,159 were colored. It is traversed by the Shenandoah, is diversified by hills, valleys, and plains, and comprises a portion of the great valley of Virginia, on the N. W. side of the Blue Ridge. The soil is very fertile. The Winchester, Potomac, and Strasburg division of the Baltimore and Ohio railroad crosses the N. W. corner. The chief productions in 1870 were 234,858 bushels of wheat, 211,028 of Indian corn, 59,618 of oats, 2,233 tons of hay, and 26,443 lbs. of wool. There were 1,769 horses, 1,499 milch cows, 3,424 other cattle, 6,248 sheep, and 5,067 swine. There were 2 grist mills, 5 saw mills, and 6 carriage factories. Capital, Berryville. **II.** A N. E. central county of Georgia, traversed by Oconee river and two of its branches;

area, about 280 sq. m.; pop. in 1870, 12,941, of whom 6,453 were colored. Granite is found in great abundance; the principal other minerals are gold, kaolin, pyrites, tourmaline, and garnets. Near the streams the land is fertile, but much of the soil in the uplands is worn out. The Athens branch of the Georgia railroad terminates at the county seat. The chief productions in 1870 were 18,103 bushels of wheat, 134,951 of Indian corn, 27,335 of oats, and 3,069 bales of cotton. There were 647 horses, 1,244 milch cows, 1,926 other cattle, 2,340 sheep, and 4,516 swine. There were 3 manufactories of cotton goods, 3 of carriages and wagons, 1 of iron castings, 2 of machinery, 1 of woollen goods, 2 grist mills, and 2 saw mills. Capital, Athens. **III.** A S. W. county of Alabama; area 1,270 sq. m.; pop. in 1870, 14,663, of whom 7,565 were colored. It is bounded W. by the Tombigbee, and S. E. by the Alabama river, both of which are here navigable by steamboats. The surface is uneven, and a considerable portion of it occupied by pine forests. Part of the soil is poor and sandy; in other places it is fertile. The chief productions in 1870 were 227,031 bushels of Indian corn, 49,550 of sweet potatoes, and 5,713 bales of cotton. There were 1,146 horses, 873 mules and asses, 3,708 milch cows, 6,921 other cattle, 4,328 sheep, and 12,646 swine. Capital, Clarks-ville. **IV.** A S. W. central county of Arkansas, bounded E. by the Washita river, and S. W. by the Little Missouri; pop. in 1870, 11,953, of whom 3,492 were colored. The former area was 941 sq. m.; but portions of Dallas and Hot Springs counties have been added to it. It is intersected by Antoine and Caddo creeks. The Washita is navigable by steamboats. The chief productions in 1870 were 4,832 bushels of wheat, 356,428 of Indian corn, and 6,531 bales of cotton. There were 1,874 horses, 767 mules and asses, 3,165 milch cows, 4,221 other cattle, 3,945 sheep, and 21,652 swine. There were 9 grist mills, 4 saw mills, and 1 leather-carrying establishment. Capital, Arkadelphia. **V.** A S. E. county of Indiana, separated from Kentucky on the S. E. by the Ohio river; area, 400 sq. m.; pop. in 1870, 24,770. The surface is mostly level, and the soil fertile. Iron, marble, limestone, and hydraulic cement are found. The Jeffersonville, Madison, and Indianapolis, the Louisville division of the Ohio and Mississippi, and the Louisville, New Albany, and Chicago railroads traverse the county. The chief productions in 1870 were 119,368 bushels of wheat, 612,192 of Indian corn, 136,295 of oats, 103,206 of potatoes, 9,020 tons of hay, 224,376 lbs. of butter, 31,030 of wool, 14,110 of tobacco, and 34,883 gallons of sorghum molasses. There were 4,475 horses, 4,024 milch cows, 4,884 other cattle, 11,787 sheep, and 22,325 swine. There were 2 manufactories of agricultural implements, 2 of boats, 3 of carriages and wagons, 2 of cars, 3 of cement, 12 of cooperage, 5 of iron castings, 3 of machinery, 7 grist mills, 5

tanneries, 7 saw mills, 7 manufactories of saddlery and harness, 8 of tin, copper, and sheet-iron ware, and 1 of woollen goods. Capital, Charleston. **VI.** A S. county of Iowa; area, 432 sq. m.; pop. in 1870, 8,735. It is drained by the South, the Whitebreast, and the east fork of Grand river. The surface is moderately uneven, and occupied mainly by prairies. The soil is generally good. The Burlington and Missouri River railroad passes through the county. The chief productions in 1870 were 125,312 bushels of wheat, 374,588 of Indian corn, 129,595 of oats, 31,863 of potatoes, 14,889 tons of hay, 203,170 lbs. of butter, and 37,209 of wool. There were 3,654 horses, 2,938 milch cows, 4,705 other cattle, 12,073 sheep, and 11,349 swine. There were 2 grist mills, 2 manufactories of saddlery and harness, and 1 of woollen goods. Capital, Osceola. **VII.** A N. E. county of Missouri; area, 516 sq. m.; pop. in 1870, 13,667, of whom 295 were colored. It is separated from Illinois by the Mississippi river, and from Iowa by the Des Moines. It has a slightly uneven surface, intersected by Fox and Wyaconda rivers, and occupied chiefly by fertile and extensive prairies, interspersed with forests of good timber. The chief productions in 1870 were 90,159 bushels of wheat, 55,336 of rye, 503,152 of Indian corn, 239,298 of oats, 33,815 of potatoes, 12,352 tons of hay, 181,507 lbs. of butter, and 60,196 of wool. There were 5,655 horses, 4,653 milch cows, 9,232 other cattle, 18,970 sheep, and 14,971 swine. Capital, Waterloo. **VIII.** A S. W. county of Kansas, bordering on the Indian territory; area, 780 sq. m.; yet unsettled. Its N. E. corner is intersected by the Nescatunga river, the S. E. corner by the Cimarron, while a branch of the latter waters its W. part. **IX.** A S. W. county of Washington territory, bounded S. and S. W. by the Columbia river, which separates it from Oregon, and watered by Yah-kotle, Cathlapootle, and Catama rivers, and other streams; area, 1,400 sq. m.; pop. in 1870, 3,081. The soil is fertile. The chief productions in 1870 were 16,735 bushels of wheat, 36,387 of oats, 30,222 of potatoes, 5,862 tons of hay, 10,944 lbs. of cheese, 86,303 of butter, and 23,144 of wool. There were 1,037 horses, 2,229 milch cows, 2,886 other cattle, 5,279 sheep, and 1,812 swine. There were 3 grist mills and 12 saw mills. Capital, Fort Vancouver.

CLARKE, Adam, LL. D., a British clergyman, born at Moybeg, Londonderry co., Ireland, in 1760 or 1762, died in London, Aug. 26, 1832. He joined the Methodist society in 1778, and soon after became a class leader and home missionary. After a short residence at the Kingswood school, in 1782 he entered the itinerant ministry, in which work he continued with few interruptions till 1805. Nearly every part of England, Ireland, Guernsey, Jersey, and the Shetland islands enjoyed his labors as a preacher and missionary. In 1805 he was appointed to London for the second time, and remained

ten years in active service as a pastor, a promoter of public charities, and a diligent student of profane and sacred literature. During the long period of his itinerant labors he had devoted much attention to oriental studies, and as early as 1798 had begun to gather materials for his "Commentary on the Bible." In 1802 he published a "Bibliographical Dictionary" (6 vols.), a work which immediately attracted the attention of scholars. Previous to his last settlement in London he had translated Sturm's "Reflections" and Fleury's "Manners of the Ancient Israelites," besides publishing "A succinct Account of Polyglot Bibles" from 1516 to 1750, and "An Account of the various Editions of the Greek Testament," from the Complutensian to that of Griesbach. On his removal to London his attainments in oriental literature directed the attention of the committee of the British and foreign Bible society to him as a fit person to superintend their publications in the oriental languages. To him was largely intrusted the preparation of their Arabic Bible. So useful were his labors in connection with this society that at the close of 1808, when the rule of the conference required his removal from London, they requested that the rule might be suspended, and he be permitted to continue his labors. This request was granted. In 1806 he had published a supplement to his "Bibliographical Dictionary," under the title of the "Bibliographical Miscellany" (2 vols.); and in 1808 appeared the first volume of his "Succession of Sacred Literature." In 1807 the university of Aberdeen conferred on him the title of A. M., and in 1808 that of LL. D. In the latter year he was intrusted by the British government with the preparation of state papers for the continuation of Rymer's *Fœdera*. On this work he labored 10 years, adding 10 folio volumes to the 20 that had already appeared. Meantime the labors upon his "Commentary" had been diligently prosecuted. The first part appeared in 1810, and in 1812 he had completed the Pentateuch and the book of Joshua. His literary attainments had now secured him membership in various learned societies at home and abroad, and his conference had honored him by thrice choosing him president of their body. The Wesleyan missionary society being organized in 1814, Clarke became the most powerful advocate of its cause, and spent much time in preaching and travelling in its interest. In 1823 he fixed his residence at Haydon hall in the vicinity of London, where he continued his labors on his "Commentary." At length, after 40 years of literary toil, the work was completed in 1826. During the period of his residence at Haydon hall he was active in the organization of Methodism in the Shetland islands, and was zealous in the promotion of various philanthropic and Christian schemes. In addition to the works already mentioned, and his "Commentaries" (6 vols. 8vo), he edited Baxter's "Christian Directory," Shuck-

ford's "Sacred and Profane History," Harmer's "Observations on various Passages of Scripture," and published "Discourse on the Eucharist" (1808), and "Memoirs of the Wesley Family," besides numerous contributions to periodicals on subjects pertaining chiefly to oriental and Biblical literature. His "Miscellaneous Works" have been collected and published in 13 vols. 8vo.

CLARKE, Charles Cowden, an English author, born at Enfield, near London, Dec. 15, 1787. He was an intimate associate of Lamb, Keats, and Shelley, and for more than 20 years was a favorite popular lecturer upon British poets and prose writers. He is author of "Nyren's Cricketer's Guide" (1833 and 1840); "Adam the Gardener," a book for the young (1834); "Tales from Chaucer" (1833 and 1870); "Riches of Chaucer" (1835 and 1870); a collection of poems entitled *Carmina Minima* (1859); "Shakespeare Characters: chiefly those subordinate" (1863); and "Molière Characters" (1865). He also wrote the "Essays on the Comic Writers of England," which appeared in the "Gentleman's Magazine" in 1871.

CLARKE, Edward Daniel, LL. D., an English traveller and mineralogist, born at Willingdon in Sussex, June 5, 1769, died in London, March 9, 1822. He was educated at Cambridge, published in 1793 travels in England, Wales, and Ireland, and afterward travelled on the continent as a tutor and travelling companion. In 1798 he was elected fellow of his college, and went to Cambridge to reside. The next year he set out as travelling companion to Mr. Cripps on a long and laborious tour through Denmark, Sweden, Lapland, Finland, Russia, Tartary, Circassia, Asia Minor, Syria, Palestine, Egypt, Greece, Turkey, Austria, Germany, and France. This journey occupied $3\frac{1}{2}$ years, and he published the results in "Travels in various Countries of Europe, Asia, and Africa" (6 vols. 4to, 1810-'23; 11 vols. 8vo, 1816-'20). On his return nearly 100 valuable classical manuscripts which he had obtained during his tour, among which was a very celebrated one of the complete works of Plato, were sold to the Bodleian library. He also placed in the vestibule of the university library at Cambridge a colossal statue of Ceres, which he had brought from Eleusis, and a number of ancient marbles from other parts of Greece, for which, as well as for his eminent attainments, the university conferred on him the degree of LL. D. He took orders in 1805, in 1807 commenced a course of lectures on mineralogy, and in 1808 became the first incumbent of the professorship of mineralogy at Cambridge. His experiments in analysis of minerals by means of the oxyhydrogen blowpipe were important. His "Life and Remains" was published in 1824.

CLARKE, Henri Jacques Guillaume, count d'Hunebourg, duke de Feltre, and marshal of France, born at Landrecies, Oct. 17, 1765, died at Neuviller, Oct. 28, 1818. He had attained

the rank of brigadier general in the army when Carnot appointed him in 1795 chief of the topographical bureau in the ministry of war, where he participated in arranging the plans which contributed to the triumphs of the French armies, and was promoted to the rank of general of division. Sent by the directory to watch the movements of Bonaparte, he was fascinated by the young hero, to whom he henceforth devoted his services. He was recalled and deprived of his rank and office by the directory; but after the 18th Brumaire he was restored to his former station, and soon intrusted with several important missions. In 1804 he was appointed councillor of state and private secretary of Napoleon on military affairs, and in August, 1807, minister of war, which post he kept until April 3, 1814. His promptness in forming an army of 60,000 soldiers and sending it against the English, who had landed in the island of Walcheren in 1809, procured for him his titles of count and duke. Napoleon had always shown a great partiality for him; but after his overthrow Clarke was among the first to join the Bourbons. He was created peer of France in June, 1814, and appointed minister of war March 11, 1815, when Napoleon was marching toward Paris. Clarke, more faithful to his new than to his old master, accompanied Louis XVIII. to Ghent, and was sent on a mission to the prince of Wales. On the second restoration he was reappointed to the ministry of war, Sept. 28, 1815, received the marshal's baton July 3, 1817, and two months later resigned his post in the cabinet and retired to private life.

CLARKE, Hyde, an English engineer and author, born in London, Dec. 14, 1815. He is the son of an engineer, and devoted himself to the same profession and the literature relating to it, and to statistics. He resided for a number of years in the East, familiarizing himself with oriental languages and promoting English enterprise in India and in connection with railways in Turkey. He has lately resided in London, and is foreign secretary and secretary for comparative philology of the ethnological society, and a member of many learned associations. Among his numerous works are "Theory of Railway Investment" (1846), "Engineering of Holland" (1849), "Comparative Philology" (1858), and an English dictionary (London, 1855; new enlarged ed., 1858) and grammar; and he has lately published the result of his studies of the Caucaso-Thibetan languages and of his prehistoric and philological researches. He speaks Turkish and other eastern languages fluently, and is a person of great industry and versatility.

CLARKE, James Freeman, D. D., an American clergyman, born in Hanover, N. H., April 4, 1810. He graduated at Harvard college in 1829, and at the Cambridge divinity school in 1833; was pastor of the Unitarian church in Louisville, Ky., from 1833 to 1840, of the church of the Disciples in Boston from 1841 to

1850, and again from 1853. He translated De Wette's "Theodore" (2 vols., 1840, in Ripley's "Specimens of Foreign Literature"); wrote the "Campaign of 1812," in the "Life and Military Services of Gen. William Hull" (1846); "Eleven Weeks in Europe" (1851); "Christian Doctrine of Forgiveness" (1852); "Service Book and Hymn Book for the Church of the Disciples" (1844 and 1856); "Memoirs of the Marchioness d'Ossoli (Margaret Fuller)," in connection with R. W. Emerson and W. H. Channing (1852); "Christian Doctrine of Prayer" (1854; new ed., 1856); "The Hour which cometh and now is" (1864); "Orthodoxy, its Truths and Errors" (1866); "Steps of Belief" (1870); "Ten Great Religions" (1871); and "Common Sense in Religion" (1874). His aim in "Orthodoxy, its Truths and Errors," was to find the essential truth in a system from which he dissented, and afterward to point out its error. The purpose of the "Ten Great Religions" is to give an account of each of these, down to the latest and best knowledge of our time, to compare each religion with Christianity, and to show the truth contained in and the deficiencies of each. His "Worship of the Church of the Disciples" combines the features of responses on the part of the congregation, as in the Episcopal service, the extempore prayer of the Congregationalists, and the silent prayer of the Friends. Besides the preceding he has published many articles in various periodicals, several poems, and a number of pamphlets. In 1863 he delivered in Boston the address on the tercentenary celebration of the birth of Shakespeare. For many years he has been one of the overseers of Harvard college, and in 1872 presented a minority report to that body in favor of the admission of women to the college. In 1863 the university conferred upon him the degree of D. D.

CLARKE, John, one of the founders of Rhode Island, born in England, Oct. 8, 1609, died at Newport, April 20, 1676. He was a physician in London, and came to Massachusetts soon after its first settlement; but being one of the friends of Anne Hutchinson, he was obliged to flee with her and her associates from that colony. Proceeding to the south, they were welcomed by Roger Williams to his vicinity, formed themselves into an organization, and obtained from the Indians an island to which they gave the name of the Isle of Rhodes or Rhode Island. The settlement commenced in 1638 at Pocasset, and Mr. Clarke began to employ himself as a preacher. In 1644 he founded at Newport the second Baptist church in America, and became its pastor. Venturing a few years later to preach in the vicinity of Boston, he was arrested by an officer of the government, was called first before a parish meeting and then before the court, and was condemned for what were adjudged false teachings to pay a fine of £20, or to be publicly whipped. He was obliged to pay his fine and leave the colony. In 1651 he was sent to Eng-

land in company with Roger Williams as an agent of the colony of Rhode Island, and published there a book entitled "Ill News from New England, or a Narrative of New England's Persecution." He remained in England after the return of Williams, till at the end of a 12 years' mission he had procured a second charter for the colony, which secured to every person at all times his own judgment and conscience in matters of religious concernment. Bancroft in his history calls him "the modest and virtuous Clarke, the persevering and disinterested envoy." Upon his return in 1663 he resumed the pastorate of his church at Newport, which he retained till his death. In his will he left his farm for charitable purposes, the income of it only to be expended; and it has since produced annually about \$200.

CLARKE, M'Donald, an eccentric American poet, born in New London, Conn., June 18, 1798, died in New York, March 5, 1842. For many years his blue cloak, cloth cap, erect military air, and beaming countenance made him one of the features of Broadway. He was ever in a glow of poetic revery, and always celebrating in verses the belles of the town and the topics of the day. He was familiarly known in the street and in society as the mad poet. Yet his oddities were all amiable; he had no vices, always preserved a gentility of deportment, and was a regular attendant at Grace church. His death was very melancholy. Being picked up by a policeman late at night in an apparently destitute and demented condition, he was placed in a cell of the city prison, and in the morning found drowned by the flow of water from an open faucet. He was buried in Greenwood cemetery, where a handsome monument was erected, with the inscription, "Poor M'Donald Clarke!" His poems were of various character, humorous, sentimental, and indignant, contain many touches of delicate sensibility, and have a vein of tenderness pervading all their grotesqueness and irregularity. Some of the titles of the collections are: "A Review of the Eve of Eternity, and other Poems" (1820); "The Elixir of Moonshine, by the Mad Poet" (1822); "The Gossip" (1825); "Poetic Sketches" (1825); and "The Belles of Broadway" (1833). His last poem was "A Cross and a Coronet" (1841).

CLARKE, Mary Anne, mistress of Frederick, duke of York, second son of George III., born in 1778, died at Boulogne in 1852. In 1809 she revenged herself upon her royal lover, with whom for some time she had not been on the best terms, by reporting to Col. Wardle the secrets of the duke's management of the army, of which he was commander-in-chief. On Jan. 27 of the same year the colonel brought the matter before the house of commons, of which he was a member. By a majority of 82 the duke was acquitted of the charge of personal corruption which the colonel's motion implied; yet on March 20 he tendered his resignation, as the evidence reflected severely upon his

character, his mistress having been the chief witness brought before the committee of the house of commons. Her testimony was delivered with great impudence of manner.

CLARKE, Mary Victoria Cowden, an English authoress, born in London, June 22, 1809. She is the eldest daughter of the composer and organist Vincent Novello, and sister of Clara Novello, the singer. In her youth she was the pupil and constant associate of Mary Lamb, and frequently met Shelley, Coleridge, Charles Lamb, Keats, Leigh Hunt, Hazlitt, Douglas Jerrold, and other literary celebrities of the day, to whose influence may be attributed the early development of her intellectual powers. In her 15th year she was a contributor to the magazines. In 1828 she was married to Charles Cowden Clarke, and soon commenced the "Concordance to Shakespeare," with which her name is so honorably connected. This work, after 16 years of uninterrupted labor, four of which were devoted to the correction of proofs and the supervision of the printing, was published in London in 1846, in a large octavo of 860 pages, each containing three closely printed columns, under the title of "The Complete Concordance to Shakespeare." Her services to Shakespearian literature by this publication have been widely acknowledged; and among the tokens of appreciation which have been bestowed upon her was a memorial from America, consisting of a chair ornamented with small figures of tragedy and comedy carved from the Shakespeare mulberry tree, and with a copy of the Stratford bust of the great dramatist. Nearly every state in the Union sent contributions to the gift. Mrs. Clarke is also the author of "The Adventures of Kit Bam, Mariner;" "The Girlhood of Shakespeare's Heroines;" a novel called "The Iron Cousin;" "The Song of Drop o' Wather, by Harry Wandworth Shortfellow" (1856); "World-noted Women" (1857); "Portia and other Stories of the Early Days of Shakespeare's Heroines" (1867); several translations of works on musical theory, and a great number of magazine articles, chiefly on subjects connected with dramatic literature. She finished in 1858, for an American publishing house, an edition of Shakespeare, without notes, but with a full glossary, the text of which, founded upon that of Dyce, was subjected to a rigid comparison with all others. In conjunction with her husband she produced "Many Happy Returns of the Day, a Birthday Book" (1860), and an annotated edition of "Shakespeare's Plays" (1869).

CLARKE, Samuel, D. D., an English clergyman, born at Norwich, Oct. 11, 1675, died May 17, 1729. He was educated at Cambridge, at a time when the philosophy of Descartes was still in vogue, and Clarke mastered it and also the new system of Newton. With a view of bringing the old system into disrepute, he translated and published before his 22d year Rohault on "Physics," with notes,

in which Newton's more splendid ideas were inserted. His translation was used until the university had acquired confidence in Newton's system. He afterward turned his attention to divinity, and became chaplain to Dr. More, bishop of Norwich. In 1699 he published some theological treatises of a practical nature, and afterward paraphrases of the four Gospels, which have often been printed. In 1704 he was appointed to deliver the Boyle lecture at Oxford, and selected as his subject "The Being and Attributes of God;" and on being reappointed the next year he took "The Evidences of Natural and Revealed Religion." These lectures were published and passed through several editions, giving rise to much controversy. About 1706 he translated into English Newton's "Optics," and was rewarded by the great mathematician with a present of £500. Queen Anne made him one of her chaplains and rector of St. James's, Westminster. At his taking the degree of D. D. he defended these two propositions: 1. No article of the Christian faith delivered in the Holy Scriptures is contrary to right reason; 2. Without liberty of human action there can be no religion. In 1712 he published his celebrated treatise "On the Scripture Doctrine of the Trinity." The book was censured by the lower house of convocation, and Clarke made some explanations, which seem to have given the bishops more satisfaction than the inferior clergy. In 1715 he began a friendly controversy on free will with Leibnitz, who died before it was concluded. The papers written on each side were printed in 1717, in English and French. On the death of Sir Isaac Newton the ministry offered him the place of master of the mint, but he declined the office as unsuitable to his ecclesiastical character. In 1712 he published Cæsar's Commentaries with notes, and in 1729 12 books of the Iliad, with learned notes and a Latin translation. His "Exposition of the Church Catechism" and 10 volumes of sermons were published after his death.

CLARKE, William, an American soldier, born in Virginia, Aug. 1, 1770, died in St. Louis, Mo., Sept. 1, 1838. In 1784 his father removed to Kentucky, and settled on the present site of the city of Louisville. Young Clarke early became acquainted with Indian warfare, and at the age of 18 he was appointed ensign and went into active service; and on March 7, 1792, he became a lieutenant of infantry. Appointed adjutant and quartermaster in 1793, he served till July, 1796, when he resigned on account of ill health. He soon after took up his residence in St. Louis, and in 1803 was appointed by President Jefferson second lieutenant of artillery, with orders to assume, in connection with Capt. Meriwether Lewis, the command of an exploring expedition across the Rocky mountains to the mouth of the Columbia, which left St. Louis in March, 1804. Clarke was the principal military director of the expedition, while he also rendered material as-

sistance to Capt. Lewis in the scientific arrangements. It was to his consummate knowledge of Indian habits and manners that the expedition owed its success. He was promoted to the rank of first lieutenant in January, 1806. The nomination of lieutenant colonel, offered him by the government, was negatived by the senate, and resigning, Feb. 27, 1807, he officiated as Indian agent till he was appointed by congress brigadier general for the territory of Upper Louisiana. In 1813 President Madison appointed him governor of the Missouri territory, which post he held until the organization of Missouri as a state in 1821, when, being nominated against his consent for governor of the state, he was defeated. In May, 1822, President Monroe appointed him superintendent of Indian affairs, which office he held till his death.

CLARKE'S FORK, or River, a branch of the Columbia, formed at the "Horse Plain," near the centre of Missoula co., Montana, lat. 47° 21' N., lon. 114° 38' W., by the junction of the Bitter Root river from the south and the Flathead from the north. It flows in a general N. W. direction, and joins the Columbia in Washington territory, lat. 48° 50' N., lon. 117° 45' W. At its mouth there is a fall of 15 ft., and a quarter of a mile above it passes through a deep gorge, where there is a further fall of 3 ft. About 130 m. above its mouth the river expands into a lake, 45 m. long and 10 or 15 m. wide, called Pend d'Oreille or Kalispelum. The Flathead river rises in the Rocky mountains, in British Columbia, about lat. 49° 30' N., flows S. into Montana, and for a short distance before joining Clarke's river pursues a W. course. About 50 m. above the junction is Flathead lake. The Bitter Root rises in the Big Hole mountains in the S. W. part of Montana, and flows first N., then N. W., and finally E. Its principal tributary is the Hell Gate, which rises in the Rocky mountains, about lat. 46° N., lon. 112° 30' W., and pursues a N. W. course. The total length of Clarke's river from the source of either tributary is about 650 m.

CLARKSON, Thomas, an English abolitionist, born at Wisbeach, Cambridgeshire, March 26, 1760, died at Playford Hall, Suffolk, Sept. 26, 1846. He was the son of a clergyman, and was educated at St. John's college, Cambridge. In 1786 he obtained the prize for the best Latin essay on the question, *Anne liceat invitos in servitutem dare?* ("Is it right to make men slaves against their will?"). The investigation necessary in the preparation of this essay aroused his interest in behalf of the slaves. He gave up his professional prospects, though he had already taken deacon's orders, and resolved to devote his life to the abolition of the slave trade. He translated his prize essay into English, and published a large edition for gratuitous circulation; formed the acquaintance of the American philanthropist Benezet, and of James Ramsay, Granville Sharp, and Lord Barham; procured intelligence from

every vessel lying in a British harbor which had been engaged in the slave trade; obtained specimens of the industry and manufactures of the native African tribes for exhibition; and finally caused an engraving to be made giving an accurate view of the interior of a slave ship, with its cells, gratings, and barricades for the confinement of the blacks. These measures created a powerful excitement in England on the subject of the traffic in slaves. Mr. Clarkson followed up these efforts by pamphlet after pamphlet, and in 1788 gave to the world his work on "The Impolicy of the Slave Trade." Immediately after the publication of this work he went to France to advocate the cause in that country. He there met with sympathy and encouragement from Louis XVI. and Necker, his celebrated minister, as well as from the most influential nobles and clerical dignitaries of the nation. Although he encountered great opposition in England, he soon found several zealous supporters, including Wilberforce, Whitbread, and Sturge. Whitbread, one of the wealthiest of his friends, offered to make good all injuries which any individual might suffer in his business from aiding and abetting in this movement. The struggle was a long one, and strenuously fought, both in parliament and out of it; every year Clarkson published a new assault on the slave trade, and every year the halls of parliament witnessed a fierce debate on the subject. The Pitt ministry were comparatively lukewarm in the cause. It was not till the accession of Mr. Fox and his friends to power in 1806 that the movement gained a decisive advantage. In 1807 the British government declared the slave trade thenceforth illegal, and in the succeeding year it was declared piracy by the United States. After a temporary relaxation from his labors, during which he published a "Portraiture of the Society of Friends," with which body he cherished a warm sympathy, and in 1813 a life of William Penn, Clarkson renewed his exertions. He obtained an interview with Alexander I. of Russia, and secured his influence in behalf of the extirpation of the traffic by all the nations of Europe; and as new duties arose from the overthrow of the system, in the establishment of the colony of Sierra Leone, in the recognition of the independence of Hayti and Liberia, and in the preparation for the emancipation of the slaves in Jamaica and Antigua, he contended for each with the same fervor which had animated him in his youth. He lived to witness the emancipation of the negroes in the West Indies in 1833, and to attend the great meeting in Exeter hall in 1840, held by the British anti-slavery society, of which he officiated as president until his death. His "History of the Abolition of the Slave Trade" (1808) is one of the best authorities on the subject. It has been translated into French by Bishop Grégoire under the title of *Histoire du commerce homicide appelé traité des noirs, ou cri des Africains*

contre leurs oppresseurs (8vo, 1822), and a new English edition was printed by the English anti-slavery society, with an anonymous preface by Lord Brougham (1839). A medal in honor of Clarkson was struck by his native town in 1846; Haydon and other eminent artists were employed to paint his portrait; his name was inscribed on the pedestal of David's statue of Gutenberg in Strasburg; and the city of London erected his statue in Guildhall.—See "Thomas Clarkson, a Monograph," by James Elmes (London, 1854).

CLASTIC ANATOMY. See ANATOMICAL PREPARATIONS.

CLATSOP, the N. W. county of Oregon, separated from Washington territory on the N. by the Columbia river, and bounded W. by the Pacific; area, 1,100 sq. m.; pop. in 1870, 1,255, of whom 13 were Chinese. On the E. border are mountains. It is watered by Lewis and Clarke river and other streams falling into the ocean. The soil is good and timber is abundant. The chief productions in 1870 were 2,007 bushels of oats, 15,130 of potatoes, and 683 tons of hay. There were 147 horses, 517 milch cows, 1,065 other cattle, 1,208 sheep, and 659 swine. Capital, Astoria.

CLAUDE, Jean, a French Protestant clergyman, born near Agen in 1619, died at the Hague, Jan. 13, 1687. He officiated as pastor at Nîmes and Montpellier, but owing to his opposition to the government scheme for the reunion of the Protestants and Roman Catholics, he was interdicted from preaching. He wrote against Arnould and Nicole on the doctrine of transubstantiation, and in 1678 held a discussion with Bossuet in presence of Mlle. de Duras, a niece of Turenne, who wished to review the grounds of her faith by hearing the arguments of these distinguished champions. Bossuet published an account of the conference, which was answered by Claude. On the very morning on which the revocation of the edict of Nantes was registered at Paris, he was ordered to leave France within 24 hours. He retired to Holland, where he was received by the prince of Orange, who settled a pension upon him. The most important of his works is his *Défense de la réformation* (Rouen, 1673).

CLAUDE LORRAINE (properly LORRAIN), a landscape painter, whose real name was CLAUDE GELÉE, born in Lorraine in 1600, died in Rome, Nov. 21, 1682. He was left an orphan at 12 years of age, displayed little intelligence in his youth, and was first made acquainted with the pencil in the home of his brother, a carver of wood at Freiburg. Subsequently he went to Rome, where he devoted himself to his profession. He is supposed to have studied about two years under Godfrey Waals, during which time he became acquainted with architectural drawing and perspective. Afterward he received instruction in painting from Agostino Tassi, and about 1625 he left Rome for a pilgrimage to the shrine of Loreto, and thence set out on a tour through

Italy, spent some time in Venice, and returned to France by the way of Tyrol and Germany. He was soon employed by the duke of Lorraine, who invited him to his house and made him very advantageous offers. After a short time he returned to Italy, and established himself in Rome, where he found ample employment. One of his earliest patrons was Cardinal Bentivoglio, who presented him to Pope Urban VIII., and for whom he painted a number of beautiful works. He was now only about 30 years of age, but had so thoroughly acquired his art that he was already recognized as one of the great masters. For more than 40 years afterward Claude continued to reside in Italy, and painted until very old. He was never married. A monument was dedicated to him in 1840 in the French church at Rome, and a statue was erected to his memory at Épinal.—Claude's great success caused him to be imitated by a host of painters, whereby a vast number of pictures were palmed upon collectors as his works. In order to detect these spurious productions, and identify his own, he made drawings of such as he was commissioned to paint, which he inscribed with the names of the purchasers. At his death he left six volumes of these drawings, which he called *Libri di verità*. One set containing 200 sketches is in possession of the duke of Devonshire; they were engraved by Earlom, and published by Boydell under the title of *Liber Veritatis*. Another is in the British museum. Rome and its environs, its Tiber and Campagna, its stupendous ruins and classic memories, furnished Claude with inexhaustible subjects for his pencil. He would spend whole days in the open air studying nature, and noting every change in the skies, or the lights and shadows of the landscape. His skies are aerial and full of brilliant effect, and there is a soft atmospheric haze over his scenes. One of his most celebrated landscapes represents a little grove of the Villa Madama, near Rome, for which Pope Clement XI. offered as much gold coin as would be required to cover the surface of the painting. His favorite periods of day were at sunrise and sunset, when objects are robed in the most delicate coloring. His figures, however, are inferior, and he frequently engaged other artists to pencil them for him. England is especially rich in the works of Claude Lorraine; the national gallery of London contains a number of them, two of which, the "St. Ursula" and the "Embarkation of the Queen of Sheba," he probably never surpassed. Four of his finest paintings were taken by Napoleon from the gallery of Cassel to Paris, where they adorned Malmaison. In 1814 the czar Alexander acquired them, and they are now in St. Petersburg.

CLAUDIA QUINTA, a Roman matron of legendary fame. Being accused of incontinency, she heard the soothsayers declare that only a virtuous woman could move the vessel conveying the image of Cybele to Rome, which had grounded on a sand bank at the mouth of the

Tiber (206 B. C.). Coming forward from among the matrons who had gone to Ostia to receive the image, and calling on Cybele to vindicate her innocence, she seized the rope attached to the vessel, which immediately moved from its sandy bed and floated. Her statue was erected in the vestibule of the temple of Cybele.

CLAUDIUS (Claudius Claudianus), an epic poet, born at Alexandria about 365, flourished in the reigns of Theodosius the Great and his two sons, Honorius and Arcadius. His education was Greek, but when grown up to manhood he went to Rome, and attached himself to Stilicho, the virtual ruler of the West on the division of the empire, with whom he became a great favorite, arriving at high honors; the great influence he possessed is proved by a statue erected in his honor discovered at Rome in the 15th century. He returned late in life to Egypt, and probably died there. His poems are very numerous, epics, lyrics, and panegyrics. Some of his epics are the *De Raptu Proserpinae*, in three cantos, not quite complete; its great defect consists in making the subject a historical event; the *Gigantomachia*, a fragment extending to 128 lines only; *De Bello Gildonico*, describing the victories of Honorius; and *De Bello Getico* or *Pollentino*, in which is described the victory of Stilicho over Alaric the Visigoth, near Pollentia, in 403. Claudian addressed many panegyrics to the distinguished men of his age, as *De Laudibus Stilichonis*, in three books, *De Bello Getico* making the fourth; three books upon the third, fourth, and sixth consulships of Honorius; and *In Rufinum*. The best edition of his works is that of the younger Burmann (Amsterdam, 1760). The first volume of a good edition by König appeared in Göttingen in 1808, and a metrical English translation of his whole works in London in 1817.

CLAUDIUS, the name of two Roman emperors. **I. Tiberius Claudius Drusus Nero Germanicus**, the fourth emperor, born at Lugdunum (Lyons), Aug. 1, 10 B. C., died A. D. 54. He was the son of Drusus and Antonia, and the grandson of Tiberius Claudius Nero and Livia, who subsequently became the wife of Augustus. In his youth he was of delicate constitution and feeble intellect, neglected and despised by his relatives, and left to the care of pedagogues, women, and slaves. He possessed, however, great industry, and became a tolerable scholar. He was 50 years old and totally inexperienced in political affairs when the murder of Caligula, A. D. 41, called him to the throne. When the timid student heard of Caligula's fate, he hid himself in a remote apartment of the palace, fearing to be the next victim. In this position he was found by a common soldier, who raised him from the ground and saluted him as emperor. Other soldiers now entered the palace and joined their comrade, and presently the despised recluse was borne to the praetorian camp, and proclaimed by the legionaries, who immediately took the oath of allegiance to

their new sovereign. His first acts were acts of mercy. The enthusiasts who had dreamed of restoring the republic were freely pardoned, while only a few of the murderers of Caligula were put to death. But soon evil counsellors alarmed him with fictitious tales of conspiracies, and continually incited him to injustice and cruelty. During his reign the southern part of Britain was subdued and converted into a Roman province, the emperor himself taking part in the conquest, and celebrating a splendid triumph in consequence of it on his return to Rome, on which occasion he obtained from the senate the surname of Britannicus. Several other wars were also waged in this reign, with the nations of Germany, Syria, and Mauritania. He constructed the famous aqueduct which was named after himself, the harbor of Ostia, and the conduit which carried the waters of Lake Fucinus to the river Liris. He was four times married. His last wife was his own niece Agrippina, who prevailed on him to set aside his son Britannicus, and to adopt hers in his stead; and who, when he repented of this act, and gave indication of his intention to annul it, killed him with poison. He was the author of several historical works, the principal of which were a history of Rome from the battle of Actium to his own times, in 41 books, and a history of Etruria, in 20 books, all lost. **II. Marcus Aurelius Claudius Gothicus**, born of humble parents in Dardania or Illyria in 214, died in 270. On the murder of Gallienus he was proclaimed emperor by the conspirators, whose choice was confirmed by the army and senate, March 24, 268. That day was signalized by a victory which the new emperor obtained over the Alemanni, in consequence of which he assumed the surname of Germanicus. The next year the Goths, having collected a vast fleet manned with over 300,000 men, entered the Euxine from one of the Scythian rivers, passed into the Ægean, and, debarking their forces on the Macedonian coast, laid siege to Thessalonica. Claudius collected a great army, and hastened to encounter the barbarians. A terrible engagement took place near Naissus (now Nissa), in which the Goths were totally defeated, with 50,000 slain. The survivors retreated to the defiles of the Hæmus, where they endeavored to make a stand against the victors; but famine, cold, and pestilence so reduced their ranks that they were soon glad to surrender on condition of having their lives spared. But the pestilence presently spread to the camp of their conquerors, and among its victims was Claudius.

CLAUDIUS, Matthias, called *Asmus*, or the *Wandsbeck messenger* (*Der Wandsbecker Bote*), from his connection with the periodical of that name, a popular German writer, born near Lübeck about 1740, died in Hamburg, Jan. 21, 1815. His poems were originally fugitive pieces which appeared from time to time in various periodicals. These he collected in 1775 and subsequent years, and gave to the

world under the title of *Asmus Omnia sua secum portans* (last ed., Hamburg, 1844). Many of his songs have been set to music. The most popular of them is the song on Rhine wine (*Rheinweinielied*), which is still sung at the German festivals. In the latter part of his life he became a convert to religious mysticism.

CLAUDIUS CÆCUS, Appius, a Roman censor, son of Claudius Appius Crassus or Crassinus, who was named dictator 337 B. C., but resigned the office because the augurs did not consider his appointment valid. Claudius Cæcus was twice *curule ædile*, but the odium which attaches to his name arises mainly from the arbitrariness with which he administered the censorship from 312 to 308. In order to form in the senate and among the people a party subservient to his designs, he filled up the vacancies in the senate with low plebeians and sons of freedmen (who were, however, set aside the next year), and enrolled a large number of the latter among all the tribes. After resigning his censorship, he was elected consul in 307. He was appointed *interrex* in the years 298 and 297. In the following year he was again chosen consul, and gained with *Volumnius* a decisive victory over the Etruscans and Samnites. He was prætor in 295, and once (in what year is unknown) he was elected dictator. The Appian road to Capua and the Appian aqueduct were built under his administration. It is believed that his secretary published the calendar and the *Legis Actiones* at his instigation. His eloquence is extolled by Livy. One of his speeches was extant in Cicero's time. He became blind (whence his surname) and crippled in his old age, and in that condition was carried into the senate, and prevailed on it to reject the terms of peace offered by Cincæas, an envoy of Pyrrhus. He was one of the earliest Roman writers known to us. Besides a poem, of which some fragments remain, he wrote a legal treatise *De Usurpationibus*, and probably also the *Actiones*, published by Flavius. He left four sons and five daughters.

CLAUDIUS CRASSUS, Appius, a Roman decemvir from 451 to 449 B. C. He belonged to the Claudii of Sabine origin, a patrician family noted for its sanguinary cruelty, and for its unrelenting opposition to the plebeians, and to laws extending their political rights. When first a consul, he opposed the Publilian law, enacted in favor of the plebeians. Afterward, when he led the legions of Rome against the enemy, he was twice defeated, the plebeians being unwilling to fight under his command. He punished many officers by flogging and death, besides ordering every tenth man to be beheaded. After the end of his consulate he opposed the revival of an agrarian law, and was sent into temporary exile. On returning he became consul for the second time, then one of the decemvirs who promulgated the ten tables, and in the following year the leading member of the new decemvirate, which added two tables to the ten. It is supposed that these

decemvirs, and Appius among them, wished to make their power perpetual; at any rate, they proved themselves arbitrary oppressors both of patricians and plebeians. On account of an inroad of the Sabines and the Æqui, the decemvirs enlisted troops, and marched against the enemy; but Appius and Opus, his colleague, remained at Rome to maintain the power of the decemvirs. Appius now fell in love with Virginia, daughter of Lucius Virginius, who was with the army, having left his daughter under the protection of Icilius. Marcus Claudius, a client of Appius, swore before the tribunal of the decemvirs that Virginia was the daughter of one of his female slaves, taken secretly by the childless wife of Virginius as her child. This scheme had been devised by Appius to bring the girl into his power. She was arrested and brought before the decemvir, who decided that she must follow her pretended master. But the people, incited by Icilius and her uncle Numitorius, threatened an outbreak, and Appius ordered Virginia to be brought to his own house, announcing that a final inquiry and decision in her case should take place the next day. During the night Virginius arrived from the camp, and appeared with Icilius and Numitorius—all three in mourning—in the forum. Appius finally adjudged the girl to his client, notwithstanding the oath and the evidence of her father, and ordered the lictors to seize and deliver her to Marcus. Virginius, seizing a knife from a butcher standing near him, stabbed his daughter, and fled to the army with Icilius and Numitorius. Two senators, Horatius and Valerius, called on the people in the city to rise against the tyrant. At the same time Virginius, Icilius, and Numitorius appealed for vengeance to the army in their camps, which, under their leading, marched upon Rome. The decemvirs resigned, and the senate decreed the restoration of the consuls and the tribunes in their stead. Appius was put in prison, and died there; according to Livy by suicide, but according to Dionysius of Halicarnassus, he was strangled by the order of the tribunes.

CLAUDIUS NERO, a Roman general, consul in B. C. 207, who inflicted a blow on the Carthaginians which contributed not a little to render the Romans victorious in the second Punic war. He was in the south of Italy contending with Hannibal, when Hasdrubal, after crossing the Alps, was advancing from the north to the assistance of his brother. Elated at having triumphed over so many difficulties, and at being on the eve of accomplishing the great object of his expedition, Hasdrubal, unconscious of danger, sent messengers to Hannibal to announce his approach. These messengers fell into the hands of the Romans, and were brought into the presence of the consul, who learned from them how imminent was the danger that hung over his country and himself. On the very day in which the messengers of Hasdrubal were seized, the consul and his legions marched

northward to form a junction with the army of Livius, and to overwhelm the Carthaginian with the combined strength of the two armies. Hasdrubal meantime, during his advance toward the south, was led by treacherous guides into an intricate and rugged region on the banks of the Metaurus, where neither his cavalry nor elephants could act, and where his army was cut to pieces and himself slain by the forces of the consuls. After this victory, which may be said to have saved Rome, Claudius Nero returned to the south with the head of Hasdrubal, which he ordered to be thrown into the camp of Hannibal as an evidence of the disaster that had at once befallen his brother, his country, and himself. Horace's *Quid debeas, o Roma, Neronibus*, was written in honor of Claudius.

CLAUDIUS NERO, Tiberius, father of the emperor Tiberius, a descendant of the preceding. He served under Julius Cæsar, and commanded the fleet which defeated that of Egypt at the Canopic mouth of the Nile (48 B. C.). He was made pontifex in place of P. Cornelius Scipio. On the murder of Cæsar he was so fearful of sharing his fate that he even proposed that his assassins should be rewarded. When the triumvirs quarrelled he fled to Perugia, where his eldest son Tiberius, the future emperor, was born; and when Perugia surrendered to Octavius, he escaped with his wife and child to Neapolis, whence he passed over to Sicily to Sextus Pompeius. Meeting with a cool reception from Pompeius, he soon departed from Sicily for Achaia, where Mark Antony was then sojourning. On the reconciliation of Antony and Octavius he returned to Rome. His wife Livia was much younger than himself, and exceedingly beautiful. Octavius saw her, became deeply enamored of her, and demanded her surrender from her husband. Claudius durst not refuse, and gave up his wife as a father would his daughter, and, when the ceremony was over, sat down to the nuptial feast with as much outward unconcern as any ordinary guest. He died soon after, leaving Octavius the guardian of his two sons.

CLAUSEL, Bertrand, count, a French soldier, born at Mirepoix, Dec. 12, 1772, died near Toulouse, April 21, 1842. He was a nephew of the revolutionist Jean Baptiste Clausel, entered the army in 1791 as sub-lieutenant, became in 1798 chief of Grouchy's staff in the so-called army of England, and accompanied Grouchy to Italy, when he prevailed upon Charles Emmanuel IV. to abdicate, the latter presenting him with Douw's celebrated picture of the "Dropsical Woman," valued at 1,500,000 francs, in token of his regard for the manner in which he had acquitted himself of a difficult diplomatic task. Clausel presented the picture to the gallery of the Louvre. In 1801 he served in Santo Domingo, after which he was general of division. In 1806 he was employed in Italy, in 1808 in Dalmatia, and in 1809 he took possession of the Illyrian prov-

inces. In 1812 he distinguished himself in Spain at the disastrous battle of Salamanca, in which he was wounded, and won the name of the unfortunate hero of the Arapiles, the total destruction of the French army having been averted by his skilful retreat after he had succeeded Marmont as commander-in-chief. In 1813, on the defeat of Joseph Bonaparte at Vitoria, he enabled Soult to protect the French frontier by impeding the progress of the English army. After Napoleon's abdication at Fontainebleau he was appointed inspector general of infantry by Louis XVIII.; but he was among the first to join the emperor after his return from Elba. He was made a senator, and appointed commander of the army of the western Pyrenees, and forced the duchess of Angoulême to leave Bordeaux. After the restoration he was sentenced to death, but escaped to the United States, where he resided several years as a planter at Mobile, and where he wrote his *Exposé justificatif*. Being amnestied in 1820, he returned to France, and in 1827 was elected to the chamber of deputies. In 1830 he was for a short time commander of the French army in Algeria, in 1831 was made a marshal, and in 1835 governor general of Algeria. An unfortunate expedition against Constantine was seized upon by his enemies as a pretext for effecting his recall; but on visiting Algeria in 1838-'9 he was warmly welcomed.

CLAUSENBURG. See **KLAUSENBURG**.

CLAUSEN, Henrik Nikolai, a Danish theologian and statesman, born at Maribø, April 22, 1793. He was the son of a celebrated preacher, and spent some time in Berlin, where Schleiermacher deeply impressed him. He became professor of theology in the university of Copenhagen, and favored in his teachings and writings a free evangelical religious development. He was president of the provincial diet from 1842 to 1846, member of the constituent assembly and of the privy council in 1848, holding the rank of a minister without portfolio, and was one of the signers of the Danish constitution, June 5, 1849. He left the cabinet in 1851, but retained his seat in the Danish diet and resumed his lectures at the university. He edited the "Periodical for Foreign Theological Literature," and published a number of theological works.

CLAUSEWITZ, Karl von, a Prussian soldier and military writer, born at Burg, June 1, 1780, died in Breslau, Nov. 16, 1831. He served in the army while a boy, and studied in the Berlin academy for young officers (1801-'3), where he attracted the attention of Gen. Scharnhorst, with whom he subsequently cooperated in the organization of the landwehr and in other military reforms. In 1806 he was adjutant of Prince Augustus, and was captured by the French. After the restoration of peace he acted till 1812 as major of the general staff, as assistant of Scharnhorst, and as military instructor of the crown prince of Prussia and of Prince Frederick of the Netherlands. He next served with distinction in the Russian army,

aided Diebitsch in concluding with York the convention of Tauroggen, and accompanied Blücher as Russian staff officer in the campaign of 1813, of which he became the historiographer at the request of Gneisenau, who was long regarded as the author of Clausewitz's *Uebersicht des Feldzugs von 1813* (Leipsic, 1814). After serving as chief of the general staff of the Russian-German legion, he assumed in 1815 the same position in the Prussian army, and became in 1818 major general and director of the military academy, and in 1831 chief of the general staff of Gneisenau's army on the Prussian-Polish frontier. He died of cholera. His most esteemed writings are *Vom Kriege, Der Feldzug von 1796 in Italien, Der Feldzug von 1815, and Ueber das Leben und den Charakter von Scharnhorst*, included in his posthumous works (*Hinterlassene Werke über Krieg und Kriegführung*, 10 vols., Berlin, 1832-'7), which rank among the best authorities on military history and science.

CLAUSTHAL, or **Klausthal**, a town of Prussia in the province of Hanover, situated on the Zellerbach, 26 m. N. E. of Göttingen; pop. in 1871, 9,138. It stands in a bleak district of the Hartz mountains, on the top and slopes of a hill, about 1,800 ft. above the sea. It is regularly laid out, having been frequently burned down and rebuilt, but the houses are generally of wood. It contains a mining school supported by the government, with a good collection of models of mines and mining machinery and of minerals, a mint, a church, court house, and gymnasium. One of the mines reaches 500 ft. below the level of the Baltic, and is drained by a tunnel cut through the mountain to a distance of 6 m. The machinery of the mines is worked by water power, and every stream in the vicinity is carefully appropriated to this purpose; the various canals, which extend from mill to mill throughout the mines, have an aggregate length of 125 m. These mines have been worked since the 11th century. About 2 m. W. of Clausthal is the silver-smelting establishment, in which 13 stamping mills are used to prepare the ore for the furnace.

CLAVICHORD, or **Clavichord**, an oblong keyed instrument, now out of use, of the nature of a spinet. The strings, being partially enveloped with cloth, emitted a soft, sweet tone, whence it was sometimes called the dumb spinet.

CLAVICLE (Lat. *claviculus*, from *clavis*, a key), the collar bone, resembling in shape the Italic letter *f*. It articulates with the sternum or breast bone, at the root of the neck, and with the acromion process of the scapula, at the shoulder. The sternal extremity is thick and triangular, with a surface for articulation with the sternum; the humeral extremity is flat and spongy, with an articular face for the acromion process of the scapula. The sternal two thirds is convex anteriorly, and the humeral third concave anteriorly. The clavicle, besides giving strength to the whole shoulder, serves to prevent it from falling inward to

the side of the chest. It also protects important vessels lying behind it. Being immediately beneath the skin, it forms a sort of ridge, which is very marked in persons who are very thin. In the male the clavicles are more curved and robust than in the female.

CLAVIERE, Etienne, a banker of Geneva, born Jan. 27, 1735, died Dec. 8, 1793. Having established himself in Paris, he became acquainted with Mirabeau, Brissot, and other leaders of the revolutionary party, and was appointed minister of finance in March, 1792. As an opponent of the extreme measures of Robespierre, he fell with the Girondists, being arrested June 2, 1793, and to escape the guillotine stabbed himself to death. His wife poisoned herself two days afterward. He wrote on financial subjects.

CLAVIGERO, Francisco Saverio, a Mexican historian, born in Vera Cruz about 1720, died at Cesena, Italy, in October, 1793. He spent 36 years in collecting historical materials in Mexico, and acquiring the native languages, living at times entirely among the Indians, noting their traditions, and examining historical paintings, manuscripts, and monuments. After the suppression by Spain of the order of Jesuits, of which he was a member (1767), he retired to Italy, and was with other Jesuits from Spanish America assigned by the pope a residence at Cesena, where he wrote *Storia antica del Messico* (4 vols. 4to, Cesena, 1780-'83). The work evinces more research than judgment. Its great merit is its impartiality, especially in relating the story of the conquest by Cortes. An English translation of it by C. Cullen was published in 1787.

CLAVIJO, Ruy Gonzalez de, one of the ambassadors of Henry III. of Castile to Tamerlane, died in Madrid in 1412. He wrote a minute account of the whole embassy, its adventures and its results. It was first published in 1582 by Argote de Molina, an antiquary of the time of Philip II., under the title of *Historia del gran Tamerlan, &c.*, though it contained only a diary of the ambassadors, beginning in May, 1403, when they embarked at Puerto Santa Maria, near Cadiz, and ending in March, 1406, when they landed there on their return. A new and excellent edition appeared in Madrid in 1782. This work contains interesting descriptions of Constantinople, Trebizond, Teheran, and of Samarcand, where the ambassadors were sumptuously entertained by Tamerlane. Clavijo on his return to Madrid was received with distinction by the king; he was one of the witnesses of the king's will, and was buried in the convent of St. Francis. His life is to be found in vol. iv. of *Hijos de Madrid, &c.* (Madrid, 1789).

CLAVIJO Y FAXARDO, José, a Spanish author, born in the Canary islands about 1730, died in Madrid in 1806. He owes his notoriety mainly to his duel with Beaumarchais, who challenged him because Clavijo had broken his promise to marry one of his sisters to whom he had paid his addresses. By the influence of Beaumar-

chais he lost the office of keeper of the archives, which he had held in Madrid; but a few years later he was appointed editor of the official paper, *El Mercurio de Madrid*, and also officiated for some time as director of a theatre. He furnished a Spanish translation of Buffon's "Natural History," for which he was rewarded by being appointed assistant director of the museum of natural history at Madrid. His adventure with Beaumarchais's sister has been dramatized by several poets, and most successfully by Goethe, who followed, however, the unfavorable sketch in the witty Frenchman's memoirs, while Clavijo is said to have been a worthy gentleman.

CLAY, a finely levigated silico-aluminous earth, found in its natural state in beds of varying depth, and in laminae of varying thickness. It is formed by the disintegration of feldspathic rocks, and the precipitation in basins from suspension in water of the finely divided, impalpable particles. It may be to a certain extent derived from slate rocks, and in such case is only the original clay from which the slate was formed, reproduced; but the original source was feldspathic or granite rock. The aluminous minerals contained in granite rocks are feldspar, mica, and hornblende. Ordinary granite is composed of quartz, feldspar, and mica. In syenitic granite mica is partly or wholly replaced by hornblende. These minerals contain alumina in varying proportions, in combination with silica, forming silicate of alumina, and they also contain alkaline silicates, either of potassium or sodium. Mica and hornblende generally contain considerable oxide of iron, while feldspar usually yields only traces, or none. Therefore, clays which are derived from feldspar are light-colored or white, while those partially made up of decomposed mica or hornblende are dark, either bluish or red. As a rule, however, feldspar is the constituent of granite in fine clay, as the particles of the other minerals do not become so finely divided, and therefore are deposited before reaching the basin where the fine clay is formed. Clay may be formed artificially from certain decomposed granites which are found in various parts of the United States, particularly in the vicinity of Washington, D. C. These beds are often found in a sufficiently soft condition to admit of being cut with the spade to the depth of 20 or 30 ft. A mass of the excavated rock is placed in a sluice and drenched with water, which is made to run into a tank. Here the coarser portions subside, while those more finely suspended run out with the water at the top into another tank, in which again there is another separation made in a similar manner, the finest particles passing into a third tank, where after a time they are precipitated. The water is then carefully drawn off, and the clay allowed to become sufficiently dry to be cut with a spade and removed. A fine white pipe clay may be procured in this manner.—Clays have varying

physical properties, depending on the admixture of other bodies, such as sand, lime, magnesia, alkalies, oxide of iron, and organic matter. Dry clay is readily separated into laminae, which, however, especially in the more tenacious varieties, break with a conchoidal fracture. It is non-crystalline, opaque, and of varying degrees of hardness, the harder kinds being nearly of the consistency of chalk. It has a strong affinity for water, which is not destroyed by moderate baking. A new clay pipe taken into the mouth sticks to the tongue and lips by absorbing the moisture from these parts. When moistened, clay emits a peculiar smell, called argillaceous, and also has a peculiar taste, which may also be so called. Mixed with considerable water, the clays are more or less plastic, the degree depending on their purity and peculiarities of composition. When subjected to a white heat they become very hard, so that they will strike fire with steel. Those clays which have a high degree of plasticity are said to be fat or long; and when possessing but little plasticity they are called lean, meagre, or short. They all shrink considerably in drying and burning, the amount depending on the quantity of water which they contain. Pure clay or silicate of alumina is infusible, but when mixed with the alkalies or alkaline earths it becomes fusible in proportion to the admixture. The principal varieties of clay used for ceramic manufacture may be divided into refractory, to which belong porcelain clays, and fusible, as potter's clay. To these may be added limey and ochrey clays.—Porcelain clay, or kaolin (a word derived from *Kao-ling*, the name of a hill in China whence the material for making porcelain is obtained), is rather softer and more crumbly than many other kinds of clay, does not form so stiff a paste with water on account of the free silica which it contains, and adheres but slightly to the tongue. It has a specific gravity of about 2.2. When separated from free silica, it has an average composition of 47 per cent. of silica, 40 of alumina, and 13 of water, having the formula $Al_2O_3, 2SiO_2 + 2aq$ (or $Al_2O_3, 3SiO_2 + 2aq$). It may be considered as derived from potash feldspar, or orthoclase, which has the formula $K_2O, Al_2O_3, 6SiO_2$, the transformation taking place by the loss of all the potash and two thirds of the silica, and a union with two equivalents of water. Some varieties, however, have a different composition, as the kaolin of Passau in Bavaria, which contains 43.65 per cent. of silica, 35.93 of alumina, 1 of sesquioxide of iron, 0.88 of carbonate of lime, and 18.5 of water; represented by the formula $4Al_2O_3, 9SiO_2 + 12aq$. Porcelain clay from Gutenberg, near Halle, contains, according to Bley, 39.02 per cent. of silica, 45 of alumina, 0.07 of carbonate of lime, 3.32 of carbonate of magnesia, 0.19 of sesquioxide of iron, and 10 of water, having approximately the formula $2Al_2O_3, 3SiO_2 + 3aq$. The Chinese and Japanese kaolins contain about twice the proportion

of silica to alumina that is found in the above European specimens, and are whiter and more unctuous to the touch. The Cornish kaolin of England, however, has an unctuous feel, and is very white and evidently formed by the decomposition of feldspar. Potters' clay, or plastic clay, contains lime and magnesia with more or less oxide of iron, either black or red. Mixed with water, it becomes exceedingly plastic; it is the common modelling material of the sculptor. The finer varieties are used for white earthenware, and the coarser for inferior ware and for drain pipes. Pipe clay is a pure variety of potters' clay, approaching somewhat in its character to kaolin, although containing less silica, and remaining more porous after baking. Fine pipe clay is found at Poole in Dorsetshire, England, and in the isle of Purbeck. It is semi-fusible, allowing the stems to be bent while hot.—Beds of fine kaolin are found at Brandon, Vt., which is used in the manufacture of paper to give weight, and the colored varieties are used in the adulteration of paint. In New Jersey, near Woodbridge, and also at South Amboy, beds of clay are worked to great extent for the manufacture of stone ware, which also furnish an excellent material for fire brick. For this purpose they must be burned twice; that is, a certain amount of clay is burned, and then ground up with another portion to make it sufficiently plastic for moulding into forms, which are again baked. Similar deposits also compose the banks of the Delaware river between Bordentown and Burlington. They all belong to the series of upper secondary rocks, underlying the greensand beds. Common brick clay is usually obtained from alluvial deposits. The color of the brick depends upon the quantity of oxide of iron in the clay. Clay beds found in Wisconsin near Lake Michigan are so free from this coloring matter that the bricks are of a straw color.—Clay for fire brick is obtained for the most part from the coal formation. Each coal bed, with very rare exceptions, rests upon a stratum of bluish gray clay, which appears of the solidity of structure of stone, though it is found to be easily cut with a knife. It often contains some carbonaceous matter lining its seams and giving them a black color, and it abounds with the fossil *stigmara* roots, which are all converted into the same material as the rest of the beds. When ground to powder in a mill, and mixed with quartz sand, obtained from the sandstone beds of the same formation, it makes an excellent quality of fire brick. Old, hard-burned brick, broken up and mixed with the clay, improves its quality, causing it to retain better its shape after moulding. Such a mixture is well adapted for the manufacture of crucibles. The following are analyses of a number of the best foreign fire clays, that of Gross Almerode being the material of which Hessian crucibles are made, with the addition of an equal weight of sand, and the Stourbridge clay that of the fire brick of this name:

Constituents, dried at 100° C.	Gross Almerode.		Beaufois, Ardennes.	Brierly Hill, near Stourbridge.		Schlen- dorf.
	Bartlier.	Salretat.	Bartlier.	Bartlier.	Salretat.	Salretat.

The clay beds of the coal formation are extensively used at Newcastle for the manufacture of large gas retorts as well as of fire brick. A number of different qualities of clay are found, all of which are from beds overlaid by coal and worked with it. Dr. Richardson gives the following analyses of these varieties:

Constituents.	1.	2.	3.	4.	5.	6.	7.

—A very singular quality of clay was long ago known in Europe, which produced bricks so light and porous that they floated upon water. The clay was found in Spain, and centuries afterward in Tuscany. Its composition was: silica 65 per cent., magnesia 17, alumina 14, and lime 4. The bricks were remarkably porous, light, and such poor conductors of heat that they might be held in the hand by one end while the other was red-hot. Clay of similar properties was afterward met with in central France, which when mixed with $\frac{1}{20}$ its weight of ordinary clay produced bricks of this character. When submitted by Ehrenberg to microscopic examination, these clays were found to consist of the shelly coverings of infusoria. Such collections of these microscopic silicious shells forming beds of clay are not uncommon in this country, particularly at the bottom of peat bogs; and it is highly probable they might be in many places turned to useful account. Ehrenberg, knowing that the clay under Berlin was composed of these organic remains, concluded that it was adapted to this use, which proved to be the case. In the banks of the river Spree it is found sometimes 100 ft. thick, of a light gray color, and almost entirely made up of these little shells, of which it takes no fewer than nine to equal the diameter of a human hair.—Besides its use for brick, tiles, and earthenware, clay is applied to several other purposes, as for the manufacture of mosaic tesserae, buttons, and artificial gems; for the manufacture of alum; for clarifying sugar by the process called claying; for producing a glaze upon paper hangings; for the

construction of adobe houses; and for the fulling or scouring of woollen cloths. The clay used for this last purpose is called fullers' earth. It is of an unctuous, soft, and dull quality, and is distinguished from other clays by falling to pieces in water with a crackling noise, instead of forming a paste as other clays do. Applied to cloth, it absorbs the oil and greasy matters. Its use has for some time been gradually giving way to that of soap. Extensive as are the uses of clay in the arts, its importance in agriculture is still greater, forming as it does the most valuable component of fertile soils.

CLAY, the name of 16 counties in the United States. **I.** A central county of West Virginia, intersected by Elk river, and bounded S. E. by Twenty Mile creek; area, 400 sq. m.; pop. in 1870, 2,196, of whom 4 were colored. The surface is diversified. The chief productions in 1870 were 39,093 bushels of Indian corn, 11,497 of oats, and 274 tons of hay. The value of live stock was \$63,096. Capital, Clay Court House. **II.** A S. W. county of North Carolina, bordering on Georgia, watered by several streams; area, about 200 sq. m.; pop. in 1870, 2,461, of whom 142 were colored. The chief productions in 1870 were 6,061 bushels of wheat, 79,985 of Indian corn, 14,408 of oats, 4,618 of Irish and 5,507 of sweet potatoes, 221 tons of hay, and 13,113 lbs. of tobacco. There were 587 horses, 945 milch cows, 2,103 other cattle, 3,154 sheep, and 5,376 swine. Capital, Haysville. **III.** A S. W. county of Georgia, bounded S. by Colomoke creek, separated from Alabama by the Chattahoochee river, and watered by its tributaries; area, about 200 sq. m.; pop. in 1870, 5,493, of whom 2,849 were colored. The Fort Gaines branch of the Southwestern railroad terminates at the county seat. The surface is level and the soil fertile. The chief productions in 1870 were 85,014 bushels of Indian corn, 18,124 of sweet potatoes, and 3,220 bales of cotton. There were 375 horses, 845 milch cows, 1,549 other cattle, and 4,281 swine. There were 4 carriage factories and 1 flour mill. Capital, Fort Gaines. **IV.** A N. E. county of Florida, bounded E. by St. John's river, and watered by its affluents and by numerous lakes; area, 430 sq. m.; pop. in 1870, 2,098, of whom 399 were colored. The Florida railroad passes through the N. W. corner. The surface is level. The chief productions in 1870 were 13,188 bushels of Indian corn, 5,322 of sweet potatoes, 6,690 gallons of molasses, and 65 bales of cotton. There were 130 horses, 1,238 milch cows, 2,620 other cattle, and 1,988 swine. Capital, Green Cove Springs. **V.** An E. county of Alabama, recently formed from portions of Randolph and Talladega counties, drained by tributaries of the Coosa and Tallapoosa rivers; area, about 700 sq. m.; pop. in 1870, 9,560, of whom 737 were colored. The soil is well adapted to agriculture. The chief productions in 1870 were 38,422 bushels of wheat,

196,886 of Indian corn, 17,005 of oats, 8,209 of sweet potatoes, 1,143 bales of cotton, 123,464 lbs. of butter, and 9,005 of tobacco. There were 959 horses, 561 mules and asses, 2,580 milch cows, 2,832 other cattle, 3,924 sheep, and 10,271 swine. Capital, Ashland. **VI.** A N. W. county of Texas, separated from the Indian territory on the N. by Red river; area, 1,100 sq. m.; pop. in 1860, 109; in 1870 not returned. It is intersected by the Big and Little Wichita rivers, and also watered by tributaries of the W. fork of Trinity river. The surface is broken and hilly; the soil well adapted to wheat and other cereals as well as to stock raising. **VII.** A N. central county of Tennessee, bordering on Kentucky, and intersected by Cumberland river, organized since the census of 1870; area, about 175 sq. m. Assessed value of property in 1871, \$685,177. Capital, Butler's Landing. **VIII.** A S. E. county of Kentucky; area, about 870 sq. m.; pop. in 1870, 8,297, of whom 495 were colored. The surface is mountainous, and is intersected by the S. fork of Kentucky river. Coal and iron are found; the manufacture of salt is carried on to a great extent, and the forests are large and numerous. The chief productions in 1870 were 7,853 bushels of wheat, 281,499 of Indian corn, 25,138 of oats, 17,774 of potatoes, 295 tons of hay, 17,673 lbs. of wool, and 17,787 of tobacco. There were 1,274 horses, 2,385 milch cows, 3,606 other cattle, 9,921 sheep, and 12,776 swine. Capital, Manchester. **IX.** A S. W. county of Indiana, drained by Eel river; area, 360 sq. m.; pop. in 1870, 19,084. The surface is level, the soil productive, and there are beds of coal and of iron ore. It is traversed by the St. Louis, Vandalia, Terre Haute, and Indianapolis railroad, and by the Wabash and Erie canal. The chief productions in 1870 were 192,118 bushels of wheat, 367,654 of Indian corn, 93,068 of oats, 50,472 of potatoes, 10,558 tons of hay, 150,252 lbs. of butter, 50,965 of wool, and 31,806 gallons of sorghum molasses. There were 4,927 horses, 3,686 milch cows, 5,560 other cattle, 20,437 sheep, and 16,234 swine. There were 5 flour mills, 5 iron foundries, 8 manufactories of carriages, 4 of bricks, 4 of stone and earthen ware, 2 of woollen goods, and 11 saw mills. Capital, Bowling Green. **X.** A S. E. county of Illinois, watered by the Little Wabash river; area, 440 sq. m.; pop. in 1870, 15,875. The surface is moderately uneven and occupied by forests and fertile prairies. It is traversed by the Springfield and Illinois Southeastern, and the Ohio and Mississippi railroads; the Chicago division of the Illinois central railroad touches the N. W. corner. The chief productions in 1870 were 87,631 bushels of wheat, 1,019,994 of Indian corn, 269,945 of oats, 41,297 of potatoes, 12,963 tons of hay, 215,416 lbs. of butter, 47,546 of wool, 24,354 of honey, and 53,310 gallons of sorghum molasses. There were 5,437 horses, 3,839 milch cows, 6,555 other cattle, 20,189 sheep, and 20,109 swine. There were 5 manufactories of carriages and wag-

ons, 5 of saddlery and harness, 1 of woollen goods, 7 flour mills, and 4 saw mills. Capital, Louisville. **XI.** A N. W. county of Minnesota, separated from Dakota territory by Red river, and intersected by Buffalo river and its branches; area, 380 sq. m.; pop. in 1870, 92. The surface is mostly prairie; the soil alluvial and fertile. A branch of the St. Paul and Pacific railroad is to cross the N. E. corner. The estimated value of farm productions in 1870 was \$1,106; of live stock, \$2,085. **XII.** A N. W. county of Iowa, drained by the Little Sioux river and its branches; area, about 600 sq. m.; pop. in 1870, 1,523. The McGregor and Missouri River railroad passes through it. The chief productions in 1870 were 15,382 bushels of wheat, 12,105 of Indian corn, 13,099 of oats, 4,414 of potatoes, and 3,684 tons of hay. There were 364 horses, 404 milch cows, 762 other cattle, and 220 swine. Capital, Peterson. **XIII.** A S. E. county of Nebraska, intersected in the S. W. part by Little Blue river, and watered in the north by the W. fork of the Big Blue; area, 576 sq. m.; pop. in 1870, 54. The surface is undulating prairie, and the soil fertile. **XIV.** A W. county of Missouri, bounded S. by the Missouri river; area, 415 sq. m.; pop. in 1870, 15,564, of whom 1,846 were colored. The surface is somewhat uneven, and partly occupied by forests of oak, black walnut, ash, and other trees. The soil is fertile, and rests upon a basis of sandstone and limestone. The Cameron and Kansas City branch of the Hannibal and St. Joseph, and the western division of the North Missouri railroad traverse it, and the Lexington and St. Joseph branch of the latter touches the N. E. corner. The chief productions in 1870 were 197,214 bushels of wheat, 1,844,270 of Indian corn, 199,604 of oats, 83,277 of potatoes, 5,961 tons of hay, 253,805 lbs. of butter, 57,732 of wool, and 31,040 of tobacco. There were 5,884 horses, 1,562 mules and asses, 3,979 milch cows, 10,424 other cattle, 17,390 sheep, and 38,300 swine. There were 10 flour mills, 5 saw mills, 3 manufactories of carriages and wagons, 2 of tobacco and snuff, and 3 of woollen goods. Capital, Liberty. **XV.** A N. E. county of Kansas, intersected by Republican river and Chapman's creek; area, 660 sq. m.; pop. in 1870, 2,942. The chief productions in 1870 were 36,704 bushels of wheat, 95,145 of Indian corn, and 5,356 tons of hay. There were 1,034 horses, 1,154 milch cows, 2,044 other cattle, and 574 swine. Capital, Clay Centre. **XVI.** A S. E. county of Dakota territory, separated from Nebraska by the Missouri river, and intersected by Vermilion river; area, about 500 sq. m.; pop. in 1870, 2,621. The chief productions in 1870 were 55,602 bushels of wheat, 29,476 of Indian corn, 41,016 of oats, 19,668 of potatoes, and 8,855 tons of hay. There were 666 horses, 1,237 milch cows, 2,065 other cattle, 380 sheep, and 474 swine. Capital Vermilion.

CLAY, Cassius Marcellus, an American politician, son of Gen. Green Clay, born in Madison

co., Kentucky, Oct. 19, 1810. He graduated at Yale college in 1832, practised law in Kentucky, and was elected to the state legislature in 1835 and 1837. Removing to Lexington, he was again elected to the legislature in 1840, but was defeated in 1841 on account of his opposition to slavery. In 1844 he made a tour of the north to advocate the election of his relative Henry Clay to the presidency. In 1845 he issued in Lexington the first number of the "True American," a weekly anti-slavery newspaper; but the press was seized by a mob and sent to Cincinnati. The journal was afterward revived by Mr. Clay, who printed it in Cincinnati and published it in Lexington. Upon the breaking out of the war with Mexico in 1846, he entered the service as captain, and was taken prisoner at Encarnacion, Jan. 23, 1847. In 1848 he supported the nomination of Gen. Taylor for the presidency. The question of changing the state constitution was discussed the next year, and by the influence of Mr. Clay a large convention of emancipationists assembled at Frankfort. In 1850 he separated from the whig party and became the anti-slavery candidate for governor, receiving about 5,000 votes. On the accession of President Lincoln in 1861 he was appointed minister to Russia. Returning to the United States, he was commissioned major general of volunteers April 11, 1862, but resigned March 11, 1863, and was reappointed minister to Russia, which position he held till 1869. In 1870 he publicly supported the cause of the Cuban revolutionists, and in 1872 the election of Horace Greeley as president. A volume of his speeches, edited by Horace Greeley, was published in 1848.

CLAY, Clement Comer, an American politician, born in Madison co., Alabama, in 1819. He graduated from the law department of the university of Virginia in 1839, and was admitted to the bar of Alabama in 1840. In 1842 and 1844 he was elected to the legislature, and in 1846 judge of the county court, which office he resigned in 1848. In November, 1853, he was elected to the United States senate, and took his seat in December, 1854. In November, 1857, he was reelected for a second term of six years from March 4, 1859. In the spring of 1858 he delivered a speech in favor of the admission of Kansas under the Lecompton constitution. Later in the session he spoke in favor of a bill repealing the bounty on vessels engaged in the Newfoundland fisheries. In 1860 he was chairman of the committee on commerce. In February, 1861, he resigned his seat in the senate, and was chosen a senator in the confederate congress. In 1864 he went to Canada as one of the secret agents of the confederate government, and took part in planning the raids on the northern frontier; and in July made some unsuccessful attempts to enter upon negotiations with President Lincoln. He returned to the confederacy, but after the surrender of the armies took refuge

in Canada. Being subsequently pardoned, he resumed the practice of law in Alabama.

CLAY, Green, an American soldier, born in Powhatan co., Virginia, Aug. 14, 1757, died Oct. 31, 1826. Prompted by the example of Boone's adventurous career in Kentucky, he migrated to that district before he was 20 years of age, and entered the office of a surveyor, whose deputy he soon became; afterward he engaged in the surveying business on his own account, and by locating lands laid the foundation of a fortune. He was a representative of the Kentucky district in the Virginia legislature; was a member of the Virginia convention which ratified the federal constitution of 1789, in favor of which he spoke and voted; and was a leading member of the convention which formed the Kentucky constitution in 1799. He served for a long time in both branches of the state legislature, and was speaker of the senate. In 1813 he led 3,000 Kentucky volunteers to the relief of Gen. Harrison, then besieged in Fort Meigs by the British. He cut his way through the hostile lines, and this accession of strength to the fort forced the enemy to withdraw. Gen. Harrison left him in command of Fort Meigs, which was soon after unsuccessfully attacked by a large force of British and Indians under Gen. Proctor and the famous chief Tecumseh. For his skilful conduct of this defence, Gen. Clay received the special thanks of Gen. Harrison. At the close of the war he retired to his estate in Kentucky, and devoted the remainder of his life to agricultural pursuits.

CLAY, Henry, an American statesman, born in Hanover co., near Richmond, Virginia, April 12, 1777, died in Washington, June 29, 1852. His father, who was a Baptist preacher, died in 1782, leaving a small and encumbered property to his widow, with their seven children, of whom Henry was the fifth. His mother, a woman of decided mental force as well as of fervent piety and high moral worth, married again and emigrated to Kentucky in 1792; but Henry, having received a very limited education, remained in Richmond, and entered the office of Peter Tinsley, clerk of the high court of chancery, where he continued four years, when he began to study law under Robert Brooke, then attorney general, afterward governor of Virginia. During his clerkship he had attracted the special regard of Chancellor Wythe, who employed him as an amanuensis and directed his studies. In November, 1797, having been admitted to the bar, he removed to Lexington, Ky., where he opened an office, and soon achieved decided success, which was due in part to his winning address, and to the frank, gallant, cordial manner which was so marked in after life. He soon took part in public affairs, and in 1799, when the people of Kentucky were about to adopt a state constitution, he advocated the gradual abolition of slavery. In 1804 he was elected to the legislature, and in 1806 was

chosen to fill a vacancy in the United States senate caused by the resignation of Gen. John Adair. His first speech in that body was made to urge the erection of a bridge over the Potomac, opposite Washington; and he soon after submitted a resolution contemplating an appropriation of public lands to aid the construction of a canal around the falls of the Ohio at Louisville. He also urged upon the government the importance of promoting internal public improvements, and submitted to the senate a proposition, which was carried with but three dissenting votes, directing "the secretary of the treasury to prepare and report to the senate at their next session a plan for the application of such means as are within the power of congress to the purposes of opening roads and making canals; together with a statement of undertakings of that nature which, as objects of public improvement, may require and deserve the aid of government." Mr. Clay's fragment of a term expired with his first session; and he was again chosen in 1807 to the legislature, of which he was made speaker the next year. In December, 1808, he made a report approving the leading features of Mr. Jefferson's foreign policy, denouncing the British orders in council, and pledging to the president the enthusiastic support of Kentucky in any probable contingency. Having been stigmatized as a demagogue by Humphrey Marshall, Mr. Clay challenged his assailant. They met and fired twice, Marshall being slightly wounded at the former fire, and Clay at the latter. Their seconds then interfered, and terminated the combat. At the session of 1809-'10 Mr. Clay again appeared in the United States senate, having been elected to fill a vacancy for two years, created by the resignation of Mr. Thurston. His first speech at this session was in favor of the policy of protection. He afterward introduced a bill to enable the territory of Orleans to form a state constitution and government, and be admitted into the Union as the state of Louisiana. When the question of rechartering the first bank of the United States came up, he voted with the great mass of the younger members of his party in favor of its overthrow, and made a speech of remarkable vigor and energy against the recharter, which was frequently quoted against him after his change of views evinced in 1816. In August, 1811, he was elected a representative in congress; and on the day of his first appearance in the representatives' hall as a member, at the called session in November, he was chosen speaker by a large majority, a distinction without parallel since the meeting of the first congress. To this house the dominant party had sent, also for the first time, John C. Calhoun of South Carolina, William H. Crawford of Georgia, and Felix Grundy of Tennessee, all young, ardent, ambitious, inspired with hostility to Great Britain, and dissatisfied with the dilatory policy which the administrations of Jefferson and

Madison had pursued with regard to her. Mr. Clay constituted the committees of the house with express reference to an early declaration of war. He was one of the most zealous advocates of the bill proposing the immediate enlistment of 25,000 men, and urged the immediate construction of 10 new frigates. War having been declared, congress adjourned, July 6, 1812. During the winter session, which began Nov. 2, Mr. Clay made a speech in reply to Josiah Quincy which attracted great attention by its force and bitterness, by the vehemence of its denunciation of the federal party, its glowing eulogium on Jefferson, and its personal insolence to Quincy, whom he stigmatized as soiling the carpet on which he stood. The 13th congress was convened by the president May 24, 1813, more than six months in advance of its regular day. The war party was predominant in congress, and Mr. Clay was reelected speaker by a large majority. No effort was omitted on his part to insure and provide for a vigorous prosecution of the war. The British ministry having offered to open negotiations for peace with the United States, the proposition was readily embraced by President Madison, who designated Albert Gallatin, secretary of the treasury, and James A. Bayard, a leading federalist, as associates with John Quincy Adams in the proposed negotiations. Mr. Clay and Jonathan Russell were added after the negotiations had been formally agreed on. On Jan. 19, 1814, Mr. Clay resigned the speakership and his seat in order to sail for Europe as a peacemaker. Notwithstanding the intensity of party feeling in congress, but nine votes were recorded against the resolution of thanks for his ability and impartiality as speaker, which was now proposed and adopted. After signing the treaty at Ghent, Mr. Clay spent some months in Paris and London, and on his return to the United States in September, 1815, was warmly welcomed. During his absence he had been unanimously reelected to congress, and on the meeting of that body in December, 1815, he was once more chosen speaker without serious competition. Excepting one term (1821-'3), he continued a member of the house and its speaker till 1825. During this period his influence was exerted in behalf of the protection of domestic industry through the encouragement of American manufactures, and the development of the national resources by means of internal improvements. But on a single question, that of a national bank, he now frankly avowed that his views had been changed by the disastrous financial experiences of the late war; that he was now as decidedly favorable to such an establishment as he had formerly been hostile to it. The bill chartering the second United States bank became a law in April, 1816. Many who concurred with Mr. Clay in his change of views on this subject afterward changed back again, but he remained an advocate of a national

bank to the last. When the condition of Spanish America attracted public attention, Mr. Clay, in opposition to the policy of President Monroe and his cabinet, urged the recognition of the revolted Spanish colonies as independent states. His speeches in vindication of the South American patriots, and in advocacy of their immediate recognition as free and independent, are among his noblest congressional efforts, and contributed largely to the recognition by the government, in 1822, of the independence of the Spanish American states. He took a leading part in the discussion (1819-'21) relating to the admission of Missouri into the Union, and vehemently opposed any restrictions as to slavery in the proposed constitution of that state. On Feb. 2, 1821, he moved a reference of the subject to a select committee of 13, of which he became chairman; and on Feb. 10 he reported from a majority of that committee a compromise, which provided for the admission of Missouri under her slave constitution, on condition that she should never prohibit the migration to or settlement within her borders of any persons "who now are, or may hereafter become, citizens of any of the states of this Union." This proposition being rejected, Mr. Clay proposed a joint committee of conference from both houses. This committee reported the measure, known as the Missouri compromise, which was adopted. This provided that, in consideration of the admission of Missouri as a slave state, slavery should in all the remaining territories of the United States, N. of lat. 36° 30' (the southern boundary of Missouri), be forever prohibited. Mr. Clay declined to be reelected for the following congress, but was again elected in 1823, and again chosen speaker. He now warmly seconded the efforts of Mr. Webster and others in favor of the recognition of insurgent Greece as an independent nation, which prevailed. In 1824 Mr. Clay was one of the four candidates for the presidency of the United States, and received 37 electoral votes. The electoral college having failed to give any one a majority, the election devolved upon the house, whose choice was limited to the three highest candidates, Adams, Jackson, and Crawford. Mr. Clay cast his vote in favor of John Quincy Adams. This action was denounced by his enemies as "bargain and corruption," and John Randolph stigmatized it as a "coalition of puritan with blackleg," for which language he was challenged by Mr. Clay. The parties met April 8, 1826, and exchanged two shots without effect, when, Randolph having declared that he would not fire at Clay, the duel was terminated by the seconds. Upon the accession of President Adams, March 4, 1825, Mr. Clay was appointed secretary of state. The acceptance of this position, under the circumstances, was regarded by some of his friends as injudicious, and was afterward publicly acknowledged by Mr. Clay to have been an error. Mr. Adams's reelection having

been defeated, Mr. Clay retired with him, March 4, 1829. He was again elected to the senate in 1831, and in 1832 was an unsuccessful candidate for the presidency against Andrew Jackson, receiving the votes only of six states. When a collision between federal authority and South Carolina seemed imminent on the tariff question, Mr. Clay proposed, early in the session of 1832-'3, his tariff compromise. Its leading features were: 1, submission to the necessity of a radical reduction of the tariff; and 2, to have the change effected so slowly and gradually that manufacturers might adapt themselves to and bear up against it. To this end, the bill provided for an ultimate reduction of all duties then ranging above 20 per cent. to that uniform rate, but only one tenth of the excess was to be deducted annually, so that the last instalment would only take effect in 1842. This proposition was generally acceptable, and, though opposed by Mr. Webster and not favored by President Jackson, passed both houses by large majorities. During the session of 1834-'5 the difficulty growing out of former French spoliation on American commerce assumed a threatening aspect. Upon the failure of the government of France to make the reparation which had been agreed upon, President Jackson, in his message of December, 1834, proposed that congress should authorize him to secure the required indemnity by reprisals on French property. The proposition was referred by the senate to its committee on foreign affairs, of which Mr. Clay was chairman; and he (Jan. 6, 1835) made a report maintaining that the failure to pay had been unintentional on the part of the French ministry, and that the government would not be justified in resorting to the forcible reprisals recommended by the president. It was unanimously resolved by congress that any legislation at this time with respect to our relations with France was inexpedient; and thus the friendly relations with that country continued uninterrupted. In June, 1836, Mr. Clay, from the committee on foreign affairs, reported in favor of recognizing the independence of Texas, whenever satisfactory evidence should be received that she had a civil government in successful operation. The proposition, somewhat modified, passed both houses without opposition. In the autumn of that year he was chosen president of the American colonization society, in place of President Madison, recently deceased. During the winter following he was reelected to the senate, receiving 76 votes to 54 for James Guthrie, the administration candidate. When the financial stricture caused by the great commercial revulsion of 1837 demanded congressional legislation, Mr. Clay led the opposition in the senate to the administration project of an independent treasury, and indicated his preference for a modified national bank. In February, 1839, he delivered a carefully prepared speech on

the subject of slavery, taking decided ground against the idea of immediate abolition as visionary and impracticable. In December of that year the opposition, or whig party, held a national convention to nominate candidates for president and vice president, when the names of Mr. Clay, Gen. Harrison, and Gen. Scott were submitted. A decided plurality of the delegates were in favor of Mr. Clay's nomination, but no one got a majority until, after three days' balloting, Gen. Harrison received the nomination, and after an animated canvass was elected by a great majority over Mr. Van Buren. Much feeling was evinced by the more ardent friends of Mr. Clay, not only in the convention but throughout the country; but he promptly signified his acquiescence in the choice. He remained in the senate, and was recognized in congress as the leader of the now dominant party there. Under his guidance the two houses rapidly matured and passed bills repealing the independent treasury system, incorporating instead a new bank of the United States, distributing prospectively the proceeds of the public lands among the states, and enacting a national bankrupt law. President Harrison died a month after his inauguration, and was succeeded by the vice president, John Tyler of Virginia, who vetoed the second of these measures, but indicated to his friends the outlines of a bank which would meet his approval. Such a bank was immediately chartered, but this was in turn vetoed. This second veto caused an immediate and irreparable breach between President Tyler with his supporters and the great body of the whigs who sympathized with Mr. Clay. The members of Tyler's cabinet, Mr. Webster excepted, resigned their posts. The chasm between the "Tyler men" and the "Clay whigs" grew daily wider and deeper, and the consequent reversion of power to the party so lately overwhelmed at the polls was inevitable.—In March, 1842, Mr. Clay resigned his seat in the senate, with the intention of retiring from public life; but in May, 1844, he was nominated with great unanimity for the presidency by the whig national convention. On the leading issue of the campaign, the annexation of Texas, Mr. Clay declared that he did not object to annexation *per se*, nor yet on account of slavery, but was opposed to any absorption of Texas while she should remain at war with Mexico, and her soil should continue to be claimed by that nation as a part of her territory. These sentiments were shared by a very large portion of the American people; but Mr. Polk, who was the democratic candidate for the presidency, and an avowed annexationist, was elected, receiving 170 electoral votes to 105 for Mr. Clay. Mr. Clay's name was one of the most prominent before the whig national convention which assembled in Philadelphia, June 7, 1848, but Gen. Zachary Taylor finally received the nomination. During the year 1849, the people of Kentucky having re-

solved to remodel their state constitution, Mr. Clay urged them to embody therein the principle of gradual emancipation; but they overruled this suggestion by a very decided vote, as they had done half a century before.—Mr. Clay was once more chosen in December, 1848, to the United States senate, for a full term of six years from the 4th of March ensuing, and took his seat Dec. 3, 1849, 43 years after his first appearance in that body. On Jan. 29, 1850, he submitted to the senate a proposition for "an amicable arrangement of all questions in controversy between the free and the slave states growing out of the subject of slavery." The resolutions, while maintaining the non-existence by law of slavery in the territory acquired by the United States from Mexico, declared that in establishing territorial governments in such territory congress should impose no restriction or condition on the subject of slavery. They further provided for the admission of California to the Union, without any restriction by congress as to slavery; opposed the abolition of slavery and the prohibition of the slave trade in the District of Columbia; and declared that congress had no power to prohibit or obstruct trade in slaves between the several slaveholding states, and that more effectual provision should be made for the rendition of fugitive slaves. The memorable discussion upon these questions was followed by the passage of the fugitive slave law, and of bills admitting California to the Union, organizing the territories of New Mexico and Utah without restriction as to slavery, and prohibiting the slave trade in the District of Columbia. Mr. Clay's last efforts in the senate were in favor of a revision of the tariff of 1846, with a view to additional protection, and of appropriations for internal improvements. During the session of 1851-'2, owing to feeble health, he was in his seat but a few days. He was visited in his room by Louis Kossuth, to whom he expressed sympathy for the struggles and sufferings of Hungary, but aversion to any intervention by the United States government in the sanguinary strifes of Europe. This was his last formal avowal of his sentiments on any public question. He continued to sink gradually till June 29, 1852, when he died. Congress assembled the same day, and each house immediately adjourned, after listening to an announcement of his death. The next day the event was the subject of orations by the leading members of both houses.—The bank question is often cited as the only important topic on which Mr. Clay's early impressions with regard to a true national policy were essentially changed. It should be noted that he, though among the earliest, most vehement, and persistent advocates of the war of 1812, was never during his 40 years of subsequent public service the adviser of any war whatever, but earnestly resisted every incitement to hostilities, and counselled the preservation of peace. "As a leader in a delibera-

tive body," said a political opponent in the senate, "Mr. Clay had no equal in America. In him, intellect, person, reason, eloquence, and courage united to form a character fit to command. He fired with his own enthusiasm, and controlled by his amazing will, individuals and masses."—Mr. Clay married in 1799 Lucretia Hart, who died April 6, 1864, at the age of 83 years. To them were born six daughters, of whom the last died in 1835, and five sons. Of the latter, HENRY, born in 1811, was killed at the battle of Buena Vista, Feb. 23, 1847. JAMES B., born in 1817, was a representative in congress in 1857-'9 from the district formerly represented by his father, and died in Montreal, Jan. 26, 1864. THOMAS HART, born in 1803, was appointed by President Lincoln minister to Nicaragua, and afterward to Honduras; he died at Lexington, Ky., March 18, 1871.—The speeches and writings of Mr. Clay have been published in several collections, but the most complete edition with a biography is by the Rev. Calvin Colton (6 vols., New York, 1857; revised ed., 1864).

CLAYBORNE, William, one of the settlers of Virginia, and a member of the council and secretary of that colony. In 1627 the governor of Virginia gave him authority to discover the head of Chesapeake bay, or any part of Virginia lying between lat. 34° and 41° N. In 1631 Charles I. granted him a license to make discoveries and trade. He established a trading post on Kent island in Chesapeake bay, not far from the site of the present capital of Maryland, Annapolis. A dispute soon arising between Lord Baltimore, the proprietary, and Virginia, the privy council left the parties to the course of law. Clayborne continued to claim Kent island and to repudiate the jurisdiction of the infant Maryland; and at length Lord Baltimore gave orders for his arrest. An engagement took place, April 23, 1635, between a small armed vessel cruising under the auspices of Clayborne and two vessels sent out by the Marylanders. One of the Marylanders being killed, Clayborne, although not arrested, was indicted and found guilty of murder, piracy, and sedition—constructive crimes inferred from his determined opposition and obstinate insubordination. He took refuge in the more settled part of Virginia, and his estate on Kent island was seized by the Maryland authorities as forfeited. Sir John Harvey, governor of Virginia, refusing to surrender Clayborne to the Maryland commissioners, he went over to England, accompanied by witnesses, to have the matter investigated. He presented to Charles I. a petition setting forth his grievances; and in 1638 the king severely reprimanded Lord Baltimore for having, in violation of his royal commands, ousted Clayborne from his rightful possessions in Kent island and slain several persons inhabiting there. Nevertheless, in the ensuing year the lords commissioners of plantations, with Archbishop Laud at their head, made a deci-

sion absolutely in favor of Lord Baltimore. In 1645 Clayborne at the head of a body of resolute insurgents expelled Leonard Calvert, deputy governor, and seized the reins of his diminutive government. In the following year Calvert, who in his turn had fled to Virginia, was reinstated, yet Clayborne escaped with impunity. In 1651 he was appointed by the English council of state one of the commissioners for the reduction of Virginia to obedience to the commonwealth of England, and he subsequently took part in reducing Maryland also. Shortly after Clayborne was made secretary of state of Virginia, and held that office until after the restoration, when he was succeeded by Thomas Ludwell. During Bacon's rebellion he was a member of the court martial that sat upon the trial of the rebel prisoners. He lived in the county of New Kent, and it is probable that he died there at an advanced age. As an explorer he was adventurous and indefatigable; and he was fearless, energetic, and indomitable in defence of the rights of Virginia. His descendants are numerous, and are found in various parts of the United States, and several of them have been distinguished men. The name is now spelt Claiborne.

CLAYS, Paul Jean, a Belgian painter, born in Bruges in 1819. He studied with Gudin in Paris, and has devoted himself chiefly to marine painting. His chief works comprise "The Catarina, Portuguese xebec, disabled, in sight of a French fleet," "The Entrance of Queen Victoria into the Port of Ostend," "The Coast of Flanders," "The Environs of Le Tréport," and "The Dike of Ostend."

CLAYTON. I. A W. central county of Georgia, bounded S. W. by Flint river; area, about 150 sq. m.; pop. in 1870, 5,477, of whom 1,743 were colored. The surface is diversified, and in parts the soil is fertile. It is traversed by the Macon and Western railroad; the Atlanta and West Point railroad touches the N. W. corner. The chief productions in 1870 were 13,814 bushels of wheat, 64,319 of Indian corn, 8,714 of oats, 6,924 of sweet potatoes, and 1,221 bales of cotton. There were 292 horses, 683 milch cows, 1,072 other cattle, and 2,599 swine. Capital, Jonesborough. **II.** A N. E. county of Iowa, bordering on Wisconsin, bounded E. by the Mississippi river, and intersected by Turkey river; area, about 760 sq. m.; pop. in 1870, 27,771. There are lead mines in the southeast; the woodlands are extensive, and water power is abundant. Fertile prairies occupy a great part of the surface. The McGregor and Missouri River railroad passes through it. The chief productions in 1870 were 1,073,219 bushels of wheat, 940,784 of Indian corn, 623,459 of oats, 57,254 of barley, 135,794 of potatoes, 31,290 tons of hay, 716,298 lbs. of butter, and 33,491 of wool. There were 8,988 horses, 8,761 milch cows, 11,846 other cattle, 11,891 sheep, and 29,186 swine; 10 flour mills, 10 saw mills, 11 carriage

factories, 4 of machinery, 11 of saddlery, 3 of cigars, and 6 breweries. Capital, Elkader.

CLAYTON, a village and township of Jefferson co., New York, and a port in the collection district of Cape Vincent; pop. of the township in 1870, 4,082; of the village, 1,020. It is at the terminus of the Utica and Black River railroad, on the St. Lawrence and Champlain rivers, and has a landing for vessels plying on the St. Lawrence.

CLAYTON, John, an American botanist, born at Fulham, England, about 1690, died in Virginia, Dec. 15, 1773. When about 20 years old he emigrated to Virginia, of which province his father had been appointed attorney general. He was educated as a physician, and was indefatigable in his botanical researches, addressing papers on the natural history of Virginia to the royal society of London, which were published in the "Philosophical Transactions." He also forwarded dried specimens of the flora of Virginia to Gronovius, who in conjunction with Linnæus published an account of a portion of them (*Flora Virginica*, parts i. and ii., Leyden, 1739-'43). The remainder were described in a third part by the son of Gronovius. Gronovius gave the name *Claytonia* to a genus of purslanes.

CLAYTON, John Middleton, an American statesman, born in Sussex co., Delaware, July 24, 1796, died at Dover, Nov. 9, 1856. He graduated at Yale college in 1815, and soon after began the practice of law in his native state, where he rapidly gained distinction. He was elected to the state legislature in 1824, and subsequently became secretary of state. In 1829 he was elected to the United States senate, and two years afterward was a member of the convention to revise the constitution of Delaware. He was reelected to the senate as a whig in 1835, but resigned his seat in 1837 to accept the appointment of chief justice of Delaware, which office he held for three years. He again served as United States senator from 1845 to 1849, when he became secretary of state in the cabinet of President Taylor, and held that post until the death of the president in July, 1850, when he was succeeded by Daniel Webster. Mr. Clayton was again elected to the senate in 1851, and continued a senator until his death. In the senate he early distinguished himself by a speech during the famous debate on Foote's resolution, which, though relating merely to the survey of the public lands, brought into discussion the whole subject of nullification. He also made an impressive argument in favor of paying the claims for French spoliations. One of his most remarkable speeches was delivered in 1855 against the message of President Pierce vetoing the act ceding public lands for an insane asylum. While secretary of state, he negotiated in 1850 the celebrated treaty with England, known as the Clayton-Bulwer treaty, guaranteeing the neutrality of and encouragement to lines of interoceanic communication across

Nicaragua or elsewhere. In 1851 he zealously defended that treaty in the senate, and vindicated Taylor's administration, and his own character as a statesman.

CLAZOMENÆ (now *Kelisman*), one of the 12 cities of the Ionian confederacy (Dodecapolis), in Asia Minor, on the bay of Smyrna. It was originally built on the isthmus connecting the Ionian peninsula with the mainland, 20 m. S. W. of Smyrna, but subsequently transplanted from fear of the Persians to an island of the bay, which Alexander the Great afterward connected with the continent by a pier, remains of which are still visible. Clazomenæ was founded by the Colophonians, but its inhabitants were not exclusively Ionians. During the Peloponnesian war it belonged to the Athenian league, revolted, and returned to its allegiance. No remains of the ancient city exist, the very stones having been carried away to Smyrna and elsewhere. Near it is the modern village of Vurla, where there is an American missionary school. Anaxagoras was born here.

CLEANTHES, a Greek Stoic philosopher, born at Assus in Asia Minor about 300 B. C., died in Athens about 220. He followed the profession of an athlete, till, fleeing from a civil commotion, he arrived in Athens. Here he supported himself as a water-carrier for gardens, and began to study philosophy, working by night, and applying himself to the lessons of Crates and Zeno by day. He was a disciple of the latter for 19 years, and succeeded him as the head of the Stoic school. He was so slow of conception that he was named "the ass," so laborious that he was styled the second Hercules, and he lived so austere from his secret nocturnal labors that the areopagus summoned him to give an account of his mode of life, and then voted him a present of 10 minæ, which Zeno, however, forbade him to receive. The Athenians held him in the highest esteem, and but for his interposition would have banished a comic poet who ridiculed him on the stage. He died by voluntary starvation, when an ulcer threatened to be fatal to him. He wrote many philosophical works, only fragments of which remain. A hymn to Jupiter by him has been preserved by Stobæus, in which he recognizes one supreme God, omnipotent and eternal, who governs nature by an immutable law. It is contained with a Latin version in Cudworth's "Intellectual System." An English translation is found in F. W. Newman's work entitled "The Soul."

CLEARCHUS, a Lacedæmonian general, distinguished in the last years of the Peloponnesian war, and at its close sent to Thrace to protect the Greeks against the barbarians. Recalled by the ephors, he refused to obey, and was sentenced to death. He then went over to Cyrus the Younger, governor of Lydia and other provinces of Asia Minor, and followed him (401 B. C.) as commander of 13,000 enlisted Greek mercenaries, on his expedition against his brother Artaxerxes II. None of his fol-

lowers knew the secret aim of their long marches from province to province until they reached the plains of Babylonia, and the skill of Clearchus in leading them was as admirable as his valor. At the battle of Cunaxa Clearchus commanded the right wing of the Grecian army; and after the death of Cyrus, when the Greeks retreated fighting, he was tacitly recognized as their commander-in-chief. He and his chief officers having accepted the invitation of Tissaphernes, the Persian commander, to come to a friendly conference in his camp, they were seized, sent to the court of Artaxerxes, and put to death. Left without commanders and in despair, the Greeks were saved by Xenophon, who admirably led their retreat, no less admirably described in his *Anabasis*.

CLEAR CREEK, a N. central county of Colorado; area, about 350 sq. m.; pop. in 1870, 1,596. The surface is mountainous, the Medicine Bow range crossing the county near the centre. It is watered by South Clear creek and its tributaries. In the valleys of these streams the soil is good. Water power is plentiful. It is the principal silver-producing county of Colorado; gold is also found, gulch and placer diggings being worked to some extent. In 1870 the gold and silver ore shipped from the county amounted to \$415,066 08. Capital, Georgetown.

CLEARFIELD, a W. central county of Pennsylvania, situated mostly on the W. declivity of the Alleghany mountains; area, about 1,150 sq. m.; pop. in 1870, 25,741. The W. branch of the Susquehanna river bisects it, and near the middle of the county receives the waters of Clearfield creek. Mushannon creek runs along the S. E. boundary. The soil near the large streams is fertile, and on the uplands are good pastures and some arable tracts. The eastern part is much cut up by deep ravines, and is generally too rugged for cultivation. Anthracite coal and iron abound. The forests furnish large quantities of pine, oak, poplar, and cherry, which are conveyed down the rivers by means of rafts. The Clearfield division of the Pennsylvania Central railroad terminates at the county seat. The chief productions in 1870 were 68,724 bushels of wheat, 52,117 of rye, 245,269 of Indian corn, 375,053 of oats, 43,426 of buckwheat, 62,059 of potatoes, 19,928 tons of hay, 451,942 lbs. of butter, and 57,072 of wool. There were 4,497 horses, 5,677 milch cows, 6,454 other cattle, 18,408 sheep, and 8,626 swine; 44 saw mills, 6 flour mills, 6 tanneries, 5 manufactories of iron castings, and 6 of tin, copper, and sheet-iron ware. Capital, Clearfield.

CLEARING HOUSE. See БАНК, vol. ii., p. 282.

CLEAVELAND, a S. W. county of North Carolina, bordering on South Carolina, intersected by the First Broad river; area, about 660 sq. m.; pop. in 1870, 12,696, of whom 2,063 were colored. The soil is generally good; the surface is uneven, and marked by several consid-

erable elevations, the principal of which is King's mountain, near the S. E. border. Gold is found. The western division of the Wilmington, Charlotte, and Rutherford railroad is completed to the county seat. The chief productions in 1870 were 42,666 bushels of wheat, 236,252 of Indian corn, 67,794 of oats, 37,882 of sweet potatoes, 106,269 lbs. of butter, and 520 bales of cotton. There were 1,301 horses, 1,002 mules and asses, 2,577 milch cows, 4,119 other cattle, 8,026 sheep, and 10,602 swine. Capital, Shelby.

CLEAVELAND, Parker, an American mineralogist, born at Rowley, Mass., Jan. 15, 1780, died at Brunswick, Me., Oct. 15, 1858. He graduated at Harvard college in 1799, and then passed three years in teaching in Haverhill, Mass., and York, Me., being in the latter place also postmaster and clerk of the courts. He was a tutor in Harvard college from 1803 to 1805, when he was chosen professor of mathematics and natural philosophy, and lecturer on chemistry and mineralogy, in Bowdoin college, an office which with some modifications he retained till his death. Thus connected with this institution from its infancy, he instructed every class that graduated from it during more than half a century, and by his labors in science and his enthusiasm in teaching he contributed largely to its growth and eminence. He devoted himself especially to mineralogy, and traversed the surrounding country as far as the White mountains in prosecution of his researches, forming a very valuable cabinet. He contributed several papers to the journal of the American academy of arts and sciences, and in 1816 published his "Mineralogy and Geology," a work which earned for him the name of father of American mineralogy, and did much to associate this country with the scientific labors of older nations. It was upon the general system of Brongniart and Haüy, and was chiefly distinguished by the minute accuracy of its descriptions, and by the original information which it gave of the new localities of minerals. The correspondence of Prof. Cleaveland was now solicited by the most eminent scientific men, by Sir Humphry Davy, Sir David Brewster, Cuvier, Brongniart, and Haüy, and he received diplomas of membership from sixteen of the principal literary and scientific societies in Europe. Professorships were also tendered to him at different times by Harvard, Dartmouth, Princeton, and other colleges in the United States. A second and much enlarged edition of his "Mineralogy" appeared in 1822, and a third in 1856. In 1839 the presidency of the college was offered to him, which he declined; and from that time his efforts were chiefly as teacher and lecturer before the classes of the college and of the medical school connected with it. His genial enthusiasm in scientific pursuits, his clearness of perception, and severe official fidelity obtained for him remarkable success and popularity as an instructor. During the

53 years of his connection with Bowdoin college he failed on his own account of attending only three recitations or lectures. During this period he kept a meteorological journal, noting the weather at three different hours every day.

CLEBURNE, a N. E. county of Alabama, bordering on Georgia, watered by the Tallapoosa river; area, about 700 sq. m.; pop. in 1870, 8,017, of whom 576 were colored. It has been recently formed from portions of Calhoun, Randolph, and Talladega counties. The surface is uneven. Various minerals, including gold, lead, and iron, are found. The Selma, Rome, and Dalton railroad passes through the N. W. corner. The chief productions in 1870 were 36,739 bushels of wheat, 186,763 of Indian corn, 19,853 of oats, 15,679 of sweet potatoes, 873 bales of cotton, 83,965 lbs. of butter, and 10,997 of tobacco. There were 960 horses, 524 mules and asses, 1,976 milch cows, 3,665 other cattle, 3,871 sheep, and 10,659 swine. Capital, Edwardsville.

CLEEF, Jan van, a Flemish painter, born at Venloo in 1646, died in Ghent in 1716. His works are to be found in many churches of Flanders and Brabant. In Ghent, where they are very numerous, there is a fine picture by him in the convent of the Black Nuns, representing a sister of the order succoring persons stricken with the plague.

CLEEF, or **Cleve**, **Joost van**, a Flemish painter, born in Antwerp about 1485, died about 1530. His conceit and eccentricities bordered on insanity, and he went by the name of "The Fool." In fact he became insane before he died. He was nevertheless an artist of merit, and left some fine pictures in Flanders and Holland, among which one at Amsterdam, representing Bacchus with gray hair and a youthful face, is worthy of note.

CLEMATIS (Gr. κλήμα, tendril), a genus of mostly climbing and highly ornamental shrubs, belonging to the natural order *ranunculaceæ*. It is generically distinguished by having four valvate colored sepals, no petals, opposite leaves, and carpels bearing the styles as long feathery tails. It embraces more than 50 species, distributed eastward from Mexico to Japan, 9 of them being natives of North America. The flower is often odoriferous, and its color is white, yellow, violet, purple, or blue. The *C. vitalba* (Linn.), often called the traveller's joy, is a native of England, and is common throughout England and France, covering hedges and old walls with its ample pinnate leaves, and its panicles of white fragrant blossoms. Its leaves contain an acrid juice which irritates the skin, and were used by beggars in the middle ages to produce artificial and easily curable ulcers. The *C. flammula*, the most sweet-scented of the species, resembles the preceding, but has smaller leaves and flowers, and is indigenous and most abundant in the south of France. The *C. cirrhosa* is an elegant evergreen, with large greenish-white flowers, and is abundant in Spain and on the

Atlas mountains in Africa. The *C. viticella*, or blue clematis, is especially esteemed for forming trellises in gardens, and is distinguished by its beautiful purplish, bell-shaped

Clematis viticella.

blossoms hanging gracefully upon solitary peduncles. The genus *atragene* of Linnaeus, embracing one American and several Siberian and Alpine plants, is by most authors made a species of clematis. Among the American species are the *C. Virginiana*, or virgin's bower, having leaves with three ovate acute leaflets, numerous white flowers in paniced clusters on axillary peduncles, climbing upon shrubs along river banks, and common throughout the United States; the *C. viorna*, or leather flower, with a very glabrous, bell-shaped,

Virgin's Bower (*Clematis Virginiana*).

purplish calyx, with fruit bearing very plumose tails, and found in rich soil in the middle and southern states; and the *C. ochroleuca*, with simple and entire leaves, silky beneath, bear-

ing single large nodding flowers, yellowish within, with erect stem, growing about a foot high, and found rarely in New York, Pennsylvania, and Virginia. All the species of *Clematis* grow and blossom freely in any light soil, and they are widely esteemed in gardens for trellis-work, and for training against a wall. They may be readily propagated by layers, young cuttings, or seeds.

CLEMENS, Samuel Langhorne (MARK TWAIN), an American humorist, born at Florida, Monroe co., Missouri, Nov. 30, 1835. He attended a common school until 13 years of age, when he became an apprentice in the printing office of the "Courier" at Hannibal, Mo., and afterward worked at his trade in St. Louis, Cincinnati, Philadelphia, and New York. In 1855 he went to New Orleans, intending to take passage for Pará, to explore the Amazon, and to engage in the cacao trade; but the fact that there was no ship from New Orleans to Pará prevented the fulfilment of his plan. On his way down the Mississippi he had made friends with the pilots, and learned to steer the boat, and for the consideration of \$500 they engaged to make him a St. Louis and New Orleans pilot. He went up and down the river steering and studying the 1,275 miles of the route, and after a time received his license, and secured a situation as a pilot at \$250 a month. In 1861 his brother was appointed secretary of the territory of Nevada, and Samuel accompanied him as his private secretary. He worked in the mines for about a year, and says in his "Roughing It" that he was really worth a million dollars for just 10 days, and lost it through his own heedlessness. He then shovelled quartz in a silver mill for \$10 a week, for one week only. In the mean time he had written occasional letters to the Virginia City "Enterprise," and in the winter of 1862 he became city editor of that journal, and held the position for three years. Part of the time he reported legislative proceedings from Carson, summing up results in weekly letters to the "Enterprise," which he signed "Mark Twain." The name was a reminiscence of his steamboat days on the Mississippi, where it is the leadman's term to signify a depth of two fathoms of water. From Virginia City he went to San Francisco, and for five months was a reporter for the "Morning Call" newspaper. He then went to Calaveras county, and worked in the surface gold diggings for three months without result. Returning to San Francisco, he supported himself by newspaper work for several months. In 1866 he went to the Hawaiian Islands, remaining six months, and coming back with a high reputation, which he turned to account as a lecturer in San Francisco and through California and Nevada. He then went to the east and published "The Jumping Frog and other Sketches" (New York, 1867), which was republished in London. In the same year he embarked with a large party of travellers in the steamer

Quaker City on a pleasure excursion up the Mediterranean to Egypt and the Holy Land. Of this excursion he gave a humorous account in "The Innocents Abroad" (8vo, Hartford, 1869), of which 125,000 copies were sold in three years. He was for some time editor of a daily newspaper in Buffalo, but afterward resumed lecturing, and visited England in 1872 and 1873. His residence is at Hartford. In 1872 he published "Roughing It" (8vo, Hartford), which reached a sale of 91,000 copies in nine months. A London publisher has gathered all his sketches, many of which have not been collected in America (adding, however, many papers not written by Mark Twain), and has issued them in 4 vols. "Roughing It" and "The Innocents Abroad" have also been republished in London. Editions of all his works, in English and German, are now (1873) in course of publication in Leipsic.

CLEMENT, the name of fourteen popes and of three antipopes. **I. St. Clement**, or **Clement of Rome** (CLEMENS ROMANUS), one of the apostolic fathers, born about A. D. 30, died about 100. He is supposed to be the Clement mentioned by St. Paul in Phil. iv. 3, as one of his fellow workers, and according to tradition was baptized by St. Peter, and elected bishop of Rome in 67, or by some accounts in 91. As the most probable accounts place his death in 100, he must on this supposition have witnessed the persecution of Domitian (95-6). His martyrdom took place in the third year of Trajan; but nothing certain is known as to the manner of his death. The Roman breviary, in harmony with a very ancient tradition, states that he was thrown into the Euxine while exiled on the Tauric Chersonesus. In the Roman calendar his feast occurs on Nov. 23. His two epistles are contained in the collections of the apostolic fathers. **II. Snidger**, of Saxon birth, died at Pesarò, Oct. 9, 1047. He was successively canon of Halberstadt, chaplain to the archbishop of Bremen, bishop of Bamberg, chancellor to King Henry III., and in 1046 succeeded Gregory VI. He crowned Henry emperor, held a council at Rome for the extirpation of simony, and is believed to have died of poison. **(III.) Guibert**, antipope, a native of Parma, died in 1100. Made archbishop of Ravenna through the influence of Henry IV., he was elected pope in an assembly held at Brescia in 1080, and while Gregory VII. was closely besieged by the imperial troops in the castle of Sant' Angelo. He excommunicated the lawful pope, who in his turn laid him under his ban, and never consented to absolve him. When Gregory was delivered by Robert Guiscard and his Normans, Clement remained master of a part of Rome, held it during the pontificate of Victor III., and was expelled under Urban II. After some brief stay at Ravenna, he was enabled by the active support of the emperor to reënter Rome, whence he was finally driven under Pascal II. He died miserably after 20 years of intrusion into the papal office. **III.**

Paolo or **Paolino Scolaro**, of Roman birth, died in March, 1191. He was cardinal-priest and bishop of Palestrina, when he was elected pope at Pisa, Dec. 19, 1187. He made his solemn entry into Rome March 13, 1188, after having proclaimed a crusade against the Saracens, who had just recaptured Jerusalem. **IV. Guido Fulcodi** (**GUI FOULQUOIS**, **FOULQUES**, or **FOUQUET**), of a knightly family of St. Gilles in Languedoc, died at Viterbo, Nov. 29, 1268. Successively a soldier, jurisconsult, secretary of the king of France, bishop of Puy, archbishop of Narbonne, cardinal-bishop of Sabina, papal legate to England, and pope, he maintained throughout his whole career a uniform character of simplicity, uprightness, and unselfishness. Elected at Perugia, Feb. 5, 1265, he besought the cardinals to reconsider their vote, but was compelled to assume the duties of the pontificate. He signed the pragmatic sanction which ended the differences between the Roman and French courts, and rejected the reformation of the calendar proposed by Roger Bacon. Having ratified the cession of the kingdom of Naples to Charles of Anjou, made by his predecessor, Urban IV., he has been accused by some historians as accessory to the tragic end of Manfred and Conradin, the heirs of the Swabian dynasty. He was a decided enemy of everything that savored of nepotism; and among the letters preserved of him is one to his nephew Pierre Gros, which is a monument of the pontiff's austere disinterestedness. **V. Bertrand Garcias de Goth**, or **de Gauth**, born at Uzeste or Villandreaux, near Bordeaux, about 1264, died at Roquemaure, in Languedoc, April 20, 1314. The fact of his having been the first pope who resided at Avignon, the part which he took in the suppression of the templars, and the political game which he played with the sovereigns of Christendom, have caused the most contradictory and doubtful accounts to be written about his birth, education, election to the papal office, and the acts of his pontificate. Ordained priest at Bordeaux, he was promoted by Boniface VIII. to the bishopric of Comminges in 1295, and to the metropolitan see of Bordeaux in 1299. The Roman see became vacant July 6, 1304, and after a stormy conclave the influence of the French king caused the archbishop of Bordeaux to be elected at Perugia, June 5, 1305. Whether on account of the distracted state of Italy and the rebellious disposition of the Roman people, or because his protector Philip the Fair prevailed on him to remain within or near his dominions, Clement V. determined to fix his abode at Avignon. His first act after his enthronization was to absolve the king from the excommunication fulminated against him by Boniface VIII., and to create ten French cardinals. On the other hand, he pronounced in 1311, in a council assembled at Vienne, the charges of heresy brought against Boniface to be without foundation. In May of the following year the order of templars, after an existence of 194

years, was suppressed by a solemn bull. The bull of suppression was enforced with great cruelty by Philip the Fair, who caused the grand master and other dignitaries of the order to be burned at the stake, and seized upon all their property situated within his dominions. Clement received at Avignon the homage of Robert of Naples, and henceforth protected this prince against the imperial power. Charles, a nephew of Robert, was at the same time acknowledged as king of Hungary. He excommunicated the Venetians for having occupied Ferrara, which his troops reoccupied before the end of the year. He favored, as far as he dared, Henry of Luxemburg in opposition to Charles of Valois, the brother of the French king; had Henry crowned emperor at Rome by a commission of cardinals, and tried in vain to compel him to make peace with the king of Naples. He published in 1313 the constitutions called Clementines, which form part of the *Corpus Juris Canonici*. **VI. Pierre Roger**, born of a noble family of Limousin, died at Villeneuve d'Avignon, Dec. 6, 1352. A Benedictine monk at first, he was made bishop of Arras and chancellor to Philip of Valois, then archbishop of Rouen and cardinal, and finally elected pope May 7, 1342. He had a controversy with Edward III. of England concerning benefices, ruled that the jubilee should be celebrated every 50 instead of every 100 years, and persisted in residing at Avignon. Petrarch and Rienzi were in vain sent to him by the Romans to urge him to return to his see. Rienzi, whom the pope made his protonotary, went back to Rome, of which he became ruler under the title of tribune. The excommunication pronounced in the preceding reign against the emperor Louis the Bavarian was renewed by Clement, who also confirmed the election of Charles IV. as king of the Romans. He purchased the city and territory of Avignon from Joanna of Naples, whose husband Andrew he had crowned. Villani accuses him of cupidity and gross immorality, while Petrarch praises his culture, eloquence, and generosity. His charity was fully exhibited toward the victims of the great plague of 1348. **(VII.) Robert de Genève**, antipope, born about 1342, died in September, 1394. He was the fifth son of Amadeus of Geneva and of Maud of Auvergne and Boulogne, allied by blood to nearly all the reigning families of Europe, and successively canon of Paris, protonotary of the holy see, bishop of T erouanne and Cambrai, and in 1371 cardinal. Gregory XI. in 1376 appointed him legate or governor of the Romagna and the march of Ancona, placing under his command an army destined to reestablish the temporal authority of the Roman see in the states of the church and the north of Italy, then in open revolt against the pope. The cardinal-legate called to his assistance the famous Jehan de Malestroit, with his band of Breton freebooters composed of 6,000 cavalry and 4,000 infantry. After reducing

the Milanese, Robert and his allies endeavored in vain to terrify the Bolognese into submission, and then ravaged the surrounding territory with fire and sword. The citizens of Cesena, indignant at these atrocities, rose up against Robert, and shut him up within the walls of Murata. In this plight he invoked the aid of Sir John Hawkwood and his "White Companions," then at Faenza. On their arrival before Murata, a full pardon was promised by the cardinal to the citizens if they would open their gates. But once outside the walls, he let loose upon his besiegers the pitiless hordes of Hawkwood and Malestroit, and 5,000 persons perished. On the death of Gregory XI., the cardinals elected an Italian, who assumed the name of Urban VI. The majority of them, being Frenchmen, resented the bitter animosity shown to their nation by the new pontiff, while his haughtiness and harshness offended his own countrymen. Under these circumstances, twelve French and four Italian cardinals met at Fondi, declared the election of Urban invalid, and chose for pope Cardinal Robert, whose sole qualification for the office, besides his Genevese extraction, was his unquestioned but unscrupulous ability. He took the name of Clement VII., and became the first of the line of the antipopes of Avignon, and the prime author of what is called the great western schism. He was at first acknowledged as rightful pope by the sovereigns of Naples, Aragon, and Castile. The rest of Italy, with all Germany, England, Brittany, Hungary, and Portugal, remained faithful to Urban. France was neutral for a time, but, as the new antipope promised to reside at Avignon, Charles V. saw too many political advantages in possessing the chief of the Christian world, and thus became his ardent supporter. This division produced the most lamentable results. Naples in particular became a field of intrigue and bloody strife. The ill-fated queen Joanna was induced to pay homage to Clement, who also persuaded her to adopt as her heir Louis of Anjou, brother to the French monarch, while France and Naples entered into an engagement to expel Urban VI. from Italy. Urban met this danger by proclaiming a crusade against his enemies. England and Flanders thereupon armed themselves in his cause, and the fairest portions of the Low Countries were ravaged by Henry Spencer and his followers. Theological discussions waxed hot in the midst of these calamities, and religious men of both parties and of every Christian nation began to fear for the very existence of the Christian name. Urban VI. died in October, 1389, and Clement thereupon appealed to the cardinals to recognize him as sole pope. But the Italian cardinals elected Pietro Tommacelli, known as Boniface IX. At length, on June 30, 1394, Nicolas de Clémengis, in a memoir presented to the king of France, urged the absolute necessity of terminating the scandal of Christendom by referring their respective claims

to arbitration. The suggestion was approved by the university of Paris, and the cardinals at Avignon were induced by public clamor to urge its adoption on Clement VII. This so affected him that he was seized with sudden illness and died soon after. **VII. Giulio de' Medici**, a natural son of Giuliano de' Medici, and cousin of Leo X., born in Florence about 1475, died Sept. 25, 1534. Carefully educated by his uncle, Lorenzo the Magnificent, he became knight of Malta, grand prior of Capua, archbishop of Florence, cardinal, chancellor of the Roman church, and pope in 1523, his election having been carried over the heads of the Colonna faction. As Charles V. seemed to threaten all Italy with the yoke, Clement formed a league against him with the Venetians and the kings of France and England. The pope, unaided by his royal allies, sought together with Venice to obtain a truce from the emperor; but he soon saw Rome sacked by the Spanish troops commanded by the constable de Bourbon (1527), and became a prisoner in the castle of Sant' Angelo. After having ceded several strongholds to his enemy, and given five cardinals as hostages, he was set at liberty, made peace with the Colonnas, and fled to Orvieto. In 1530 he became reconciled with the emperor, and crowned him at Bologna. On March 23, 1534, Clement gave his judgment on the divorce of Henry VIII., declaring the marriage with Catharine of Aragon lawful and valid, condemning the proceedings against her as unjust, and commanding Henry to take her back as his lawful wife. The bill abolishing the pope's authority within the realm of England was introduced into the commons in the beginning of March, was transmitted to the lords a week later, was passed by them on March 20, and received the royal assent on March 30. "It was not possible," says Lingard, "that a transaction in Rome on the 23d could induce the king to give his assent on the 30th." Thus the judgment of Clement was not the cause of the separation of England from the Roman communion. But in May following was issued the bull which is thought to have rendered the separation irremediable. In 1533 Clement had gone to Marseilles to meet Francis I., and there affianced his niece Catharine de' Medici to the heir to the French throne. He returned to Rome a prey to a slow fever brought on chiefly by anguish of spirit, which soon proved fatal. He had succeeded in making peace with the sovereigns of Ferrara and Florence, had sent missionaries to preach the gospel in Mexico, and had vainly endeavored to correct the ecclesiastical abuses and disorders of Italy. **(VIII.) Gil Muñoz**, antipope, was canon of Barcelona when he was elected pope by the dissenting cardinals after the death of Benedict XIII. (1424). He was installed at Peñíscola, but the reconciliation of the king of Aragon, Alfonso V., with Pope Martin V., put an end to his power, and by abdicating in 1429 he terminated the schism which had divided the church

for 51 years. He received the bishopric of Majorca in compensation for his empty pontificate. **VIII. Ippolito Aldobrandini**, of a noble Florentine family, born at Fano in 1536, died March 3, 1605. Distinguished for his virtues, he became auditor of the rota, referendary of Sixtus V., and cardinal, and succeeded Innocent IX. in the papal chair, Jan. 30, 1592. The principal political movement of his reign was the favor which he showed to the league against Henry IV. of France, and the absolution which he gave to that monarch when he made public profession of Catholicism. He strove to make learning and piety flourish in the church, condemned duels, crowned the poet Tasso, and raised to the cardinalate Baronius, Bellarmin, Du Perron, and other famed men. In his reign began the controversy concerning grace, on occasion of the publication of the works of Molina, which occupied the most distinguished theologians of the 17th century. **IX. Giulio Rospigliosi**, born at Pistoja in 1600, died Dec. 9, 1669. He was auditor of legation in France, nuncio in Spain, and cardinal, and succeeded Alexander VII. June 20, 1667. He coöperated with Louis XIV. in lulling the controversy between the Jansenists and Jesuits, by obtaining subscriptions to the formula which was styled the "peace of the church." He repaired the finances of the pontifical treasury, and vainly sought to unite the Christian princes in aid of the Venetians against the Turks, who were besieging Candia. **X. Emilio Altieri**, born in Rome, July 13, 1590, elected pope, April 29, 1670, after a conclave of more than four months, died July 22, 1676. In his pontificate began the controversy with France concerning the revenues of vacant sees. He wholly abandoned the administration of the government to Cardinal Paluzzi, his nephew by adoption. **XI. Giovanni Francesco Albani**, born at Pesaro, July 22, 1649, succeeded Innocent XII. Nov. 23, 1700, died March 19, 1721. He supported Louis XIV. in the war of the Spanish succession, recognized the archduke Charles only by constraint of the imperial troops which invaded the Papal States in 1709, and the ancient fiefs of the church, Sicily, Sardinia, Parma, and Piacenza, were given to new princes. He had a controversy with Victor Amadeus II., king of Sicily, concerning ecclesiastical jurisdiction in that kingdom, and received with royal honors the son of James II., the pretender to the throne of England. He confirmed the condemnation of the five famous propositions of Jansenius by the bull *Vineam Domini* (1705); and by the bull *Unigenitus* (1713) he condemned 101 propositions extracted from the "Moral Reflections" of Quesnel. He promoted literature and the arts, and enriched the Vatican library with valuable oriental manuscripts. **XII. Lorenzo Corsini**, born at Florence in 1652, died Feb. 6, 1740. He was created cardinal in 1706 and bishop of Frascati in 1725, and was elected pope July 12, 1730, as successor of Benedict XIII. One

of his first acts was to punish Cardinal Coscia for maladministration under the last pontificate. His reign was troubled by the disagreement between the courts of Vienna and Madrid, which excited fierce wars in Italy, and he indemnified the cities of Ferrara, Bologna, and Ravenna, which had been pillaged by the imperial troops. In 1738 he invested Don Carlos with the kingdom of Naples and Sicily, adjudged to him by the treaty of Vienna. In 1740 he restored the liberties of the republic of San Marino. He at first applauded the doctrines of St. Thomas, and gave to the schools of the Dominicans the privileges of universities, but afterward showed equal favor to the anti-Thomists. He founded in 1734 the Corsini seminary, designed for the education and conversion of young Greeks; and his efforts for the promotion of the arts and sciences in Rome were more successful than his political enterprises. **XIII. Carlo Rezzonico**, born in Venice in March, 1693, became cardinal in 1737 and bishop of Padua in 1743, succeeded Benedict XIV. July 6, 1758, and died Feb. 3, 1769. He actively administered the Papal States, and was in controversy with several of the governments of Europe throughout his reign. The first question related to the Jesuits, who had been already expelled from Portugal and France, but whom he eulogized and confirmed in their former privileges by the bull *Apostolicam* (1765). This, however, did not prevent them from being exiled soon after from Spain, the Two Sicilies, Parma, and Malta. He attempted in vain to maintain ecclesiastical jurisdiction in the duchy of Parma; and when he excommunicated Duke Ferdinand in 1768, the Bourbons acted in combination against him according to the terms of the family pact, and France seized Avignon, Naples captured Benevento, and Spain added violence to the persecution of the Jesuits. A splendid mausoleum, one of the best works of Canova, is erected to his honor in the church of St. Peter. **XIV. Giovanni Vincenzo Antonio Ganganelli**, born at Sant' Arcangelo, Oct. 31, 1705, died Sept. 22, 1774. He received a learned education in the schools of the Jesuits and the convents of the Franciscans, gained distinction as a teacher of philosophy, and became successively director of the college of St. Bonaventura at Rome, cardinal, and councillor of Benedict XIV. He was elected pope as successor of the preceding, May 19, 1769, after the conclave had sat nearly three months, during which all the sovereigns of the house of Bourbon had pledged themselves either to obtain from the new pope the suppression of the Jesuits, or to throw off their allegiance to the Roman see. His predecessor, in seeking to save the Jesuits, had involved himself in a contest with almost all Europe, and in striving to maintain ecclesiastical immunities had alienated a part of his states and had diminished the respect of civil governments for the holy see. Clement XIV. suppressed the reading of the bull *In Cena Domini*,

which had irritated the Bourbon courts, but prudently and firmly resisted them when they demanded the immediate abolition of the society of Jesus. After four years of investigation into the charges brought against the society, and when Austria united with the other Catholic powers in assailing it, he at length, July 21, 1773, granted the famous brief of suppression, *Dominus ac Redemptor*. By this measure he prevented a rupture with the princes of Europe, and recovered Avignon, Benevento, and other places which had been seized by France and Naples. A man of unquestioned piety, learning, and ability, his pontificate occurred in evil days. The violence brought to bear on him by the Catholic courts in order to obtain the suppression of the Jesuits filled his soul with bitterness. Incontrovertible testimony establishes the fact that he died broken-hearted. The letters published as his by Caraccioli, his biographer, are considered unauthentic. The Clementine museum is a monument of his munificence and love for the fine arts. Theiner published a history of his pontificate (3 vols., Leipsic, 1853), which was passionately assailed by Crétineau-Joly; and the memory of the pontiff has been vindicated by the Jesuit De Ravignan (*Clément XIII. et Clément XIV.*, Paris, 1854).

CLÉMENT, Jacob, a Flemish composer of the 16th century, principal chapelmaster of the emperor Charles V. He stood at the head of his profession in the period between Desprès and Palestrina, excelled both in sacred and secular music, and was called *Clemens non papa*. Seven of his posthumous books of motets, in four parts, were published in London in 1567, and his *Missa Defunctorum* in 1580.

CLÉMENT, Jacques, a French regicide, born in Champagne about 1565, killed at St. Cloud, Aug. 1, 1589. He was a monk, and was selected at the suggestion of Bourgoing, prior of the convent of the Jacobines at Paris, as the instrument of the duke de Mayenne and the other leaders of the league for the assassination of Henry III. After having spent July 31, 1589, in fasting, and partaken of the eucharist, Clément went the next morning to St. Cloud, where, as the bearer of a letter from Achille de Harlay, he was admitted to the palace. While Henry III. was reading the letter Clément stabbed him. The king, throwing the knife which had inflicted a mortal wound into the murderer's face, exclaimed, "Oh, the wicked monk! he has killed me. Put him to death." The attendants killed him on the spot, and his remains were dragged in the mire, quartered, and burnt. The king died next morning, and Clément was proclaimed a martyr by Bourgoing, and by Pères Commelet, Guignard, and Mariana. The last named published *De Rege et Regis Institutione* (1599), in glorification of the regicide.

CLÉMENT, Jean Pierre, a French historian and political economist, born at Draguignan, June 2, 1809. He early acquired prominence as a

free-trader and as a writer on political economy and history; and in 1855 he was elected to the academy of moral and political sciences. His works include *Histoire de la vie et de l'administration de Colbert, précédée d'une notice historique sur Nicolas Fouquet* (1846); *Le gouvernement de Louis XIV.* (1848); *Jacques Cœur et Charles VII., ou la France au XV^e siècle* (2 vols., 1853); *Histoire du système protecteur en France depuis le ministère de Colbert jusqu'à la révolution de 1848* (1854); editions of *Réflexions sur la miséricorde* and of *Lettres de la duchesse de La Vallière* (2 vols., 1860); and *Lettres, instructions et mémoires de Colbert* (8 vols., 1863-'72), published under the auspices of the government, and in 1872 crowned with a valuable prize by the academy.

CLEMENT, Knut Jungbohn, a Danish historian, born on the island of Amram, N. Friesland, Dec. 4, 1803, died at Bergen, N. J., Oct. 7, 1873. After travelling in Great Britain, France, Germany, &c., at the expense of the Danish government, he became professor of history at the university of Kiel. In 1873 he visited the United States. He published several works relating to philology, and to his travels in Ireland, Friesland, Holland, and Germany. Among the principal are, in German, *Erklärende Einleitung zur Geschichte Dänemarks* (Hamburg, 1839); *Die nordgermanische Welt* (Copenhagen, 1840); *Die Lebens- und Leidensgeschichte der Friesen* (Kiel, 1845); *Die geeignetsten Mittel zur Besserung der Schleswiger und Holsteiner* (Altona, 1848); and *Das wahre Verhältniss der süd-jütischen Nationalität und Sprache* (Hamburg, 1849). In 1873 he completed, in English, his "History of Ireland" (3 vols.), from original documents and personal investigations.

CLEMENT OF ALEXANDRIA (TITUS FLAVIUS CLEMENS, surnamed ALEXANDRINUS), one of the fathers of the church, born probably at Athens about the middle of the 2d century, died in Alexandria about 215. Early devoted to the study of philosophy, he travelled through Greece and visited Italy and Egypt. He was a proficient in the Stoic and Platonic philosophies, and had also listened to Christian teachers, when through the influence of Pantænus, master of the Christian school at Alexandria, he embraced Christianity, and became the assistant, according to others the successor, of his master in the school. The persecution under Severus in 202 obliged both to seek refuge in Palestine. He visited Jerusalem and Antioch, and according to some returned to Alexandria, but appears to have been in Jerusalem in 210 or 211, for Eusebius mentions him at that date as the bearer of a letter from the bishop of Jerusalem to the church at Antioch. Little is known of the later years of his life. He had many illustrious pupils, among whom was Origen. He is distinguished among the fathers of the church by his large acquaintance with and sincere admiration of the ancient Greek philosophy. Unlike Tertullian

and Athenagoras, he esteemed philosophy a divine work, and philosophers the prophets of paganism, whose lessons were to prepare the way for Christ among the gentiles, as the Mosaic dispensation had prepared it among the Hebrews. Adopting no one of the philosophical schools, and forming no connected scheme of Christian theology, his efforts to reconcile philosophy and religion tended to allegorical interpretations of the Scriptures, and to speculations in which the metaphysician is more apparent than the Christian. Yet by his comparison of Christian with Hellenic ideas he exerted an important influence upon his age and upon the development of Christian philosophy. His three principal extant works are a hortatory address to the Greeks (*Λόγος προτροπικός πρὸς Ἑλλήνας*), on the vanity of heathenism and the superiority of the gospel; a treatise (*Παδαγωγός*) on the moral law of Christianity, rather with reference to the details of life than to general principles; and a discursive collection (*Στρωματεῖς* or *Στρώματα*), containing religious thoughts, philosophical maxims, and various information on topics of antiquity. The best complete edition of his works is by Bishop Potter, in Greek and Latin (2 vols., Oxford, 1715). The principal works concerning his life and doctrine are a special treatise of Neander (Heidelberg, 1811); Guericke, *De Schola quæ Alexandria floruit* (Halle, 1824-'5); Eylert, *Clemens von Alexandrien als Philosoph und Dichter* (Leipzig, 1832); Kaye, "Account of the Writings and Opinions of Clement of Alexandria" (London, 1835); Böhringer, *Die Kirche Christi und ihre Zeugen* (2d ed., Zürich, 1861); and Freppel, *Clément d'Alexandrie* (Paris, 1866).

CLEMENT OF ROME. See CLEMENT I., pope.

CLEMENTI, Muzio, an Italian pianist and composer, born in Rome in 1752, died at Evesham England, March 10, 1832. His father was a silversmith, and the son evinced at a very early age a passion for music, which the father fostered, providing him with the best instructors. His first master was Buroni, afterward first composer of St. Peter's. At seven he was placed under Cordicelli for instruction in thorough bass, and at nine he was so far advanced as to be able to pass successfully the rigid examination necessary for admission to the rank of organist at Rome. His next teachers were Santarelli, a distinguished master of singing at Rome, and Carpini, an equally famous contrapuntist. While under the instructions of the latter Clementi composed a mass for four voices. When Clementi was 14 years old Mr. Peter Beckford, a nephew of Alderman Beckford, being upon a visit to Rome, was so much struck with his talent, especially as a player upon the harpsichord, that he invited him to England. This invitation was accepted, and from this time his interests were mainly in England, where he eventually became a partner in a leading musical house. His first residence in that country

was at Mr. Beckford's seat in Dorsetshire, where he was received as one of the family. Here he zealously pursued his studies, becoming at the age of 18 the foremost harpsichord player of his day, and composing his second *opus*, which laid the foundation for the modern sonata form and became a model for future works of that description. This at the time was also estimated as a work of extraordinary difficulty, not to be attempted by any but the best musicians; but such advances have been made in technical skill that it is now within the reach of players of moderate ability. For some years after this Clementi played the harpsichord at the opera. His reputation increased with rapidity and extended to the continent. In 1780 he visited Paris, where he was received with enthusiasm. The following year he went to Strasburg, Munich, and Vienna. At the latter city the emperor Joseph II. invited him to his palace, and he played before the court alternately with Mozart. In 1783 John B. Cramer became his pupil, and about the same time *Opus 12*, a set of sonatas, was published, upon one of which both Samuel Wesley and Dr. Crotch delivered public lectures in London. In 1784 Clementi returned to England, where he remained till 1802, spending much of his time in teaching. Among his most eminent pupils were Cramer, John Field, Zeuner, Kalkbrenner, Berger, and Klengel. He gave up teaching in 1800, and devoted himself to perfecting the mechanism of the piano. Connecting himself in business with Mr. Colard, in time he amassed a fortune; but he was not idle in his art, composing symphonies and other works for orchestra, and also for piano; prominent among the latter being his *Gradus ad Parnassum*. He was highly esteemed in England, and passed the latter years of his life in retirement. He retained his technical skill to the close of his life, playing and improvising at the age of 80, to Cramer, Moscheles, and others, on one occasion with so much vigor and execution as to astonish his hearers.

CLEMENTINES, the name first given to a collection of pontifical constitutions and decrees published in 1313 by Clement V. They are found embodied in the *Corpus Juris Canonici*, where they form 5 books and 52 titles. In 1317 John XXII. published this body of laws in due form, and sent copies of it to the universities of Paris and Bologna. They were issued in a separate folio volume in Mentz, 1460.

CLEOBIS AND BITON. See BITON AND CLEOBIS.

CLEOBULUS, one of the seven sages of Greece, a native of Lindus in Rhodes, and the son of Evagoras, lived in the 6th century B. C. He studied philosophy in Egypt, and was remarkable for personal strength and beauty, and for his enlightened views on female education and on other subjects. He composed songs, riddles, and sayings; among others, an ingenious riddle on the year is attributed to him by Diogenes Laërtius, while others regard it as com-

posed by his daughter Cleobulina, who also wrote enigmas in hexameters, and was renowned for her accomplishments and virtues. Several of his sayings are preserved, as: "Do good to a friend to make him a better friend, and to an enemy to make him a friend;" "Learn to bear nobly the changes of fortune."

CLEOMBROTUS I., a king of Sparta of the Agid line, son of Pausanias, succeeded his brother Agesipolis I., 380 B. C. In 378 he was sent into Bœotia at the head of an army, but as he returned without effecting anything, he was not again intrusted with command till 376, when the illness of his colleague Agesilaus compelled the ephors to appoint him once more general-in-chief, but he again returned without result. In 374 he was sent into Phocis with an army to aid the Phocians in repelling the Thebans from their territory, which he effected without any contest. He remained in Phocis till 371, when he received orders to enter Bœotia and commence offensive operations against the Thebans. Having captured Creusis and 12 triremes in its harbor, he advanced to Leuctra, where he rashly gave battle to Epaminondas on ill-chosen ground and was totally defeated. He displayed heroic bravery, and was fatally wounded.

CLEOMEDES, a Greek astronomer, who flourished probably in the 1st century, was the author of a treatise on the "Circular Theory of the Heavenly Bodies," which is still extant. It consists of two books, the first of which treats of the universe in general, of the zones, of the motions of the stars and planets, of day and night, and of the magnitude and figure of the earth. The most interesting dissertations in the second book are on the magnitude of the sun and moon, and on the illumination, phases, and eclipses of the moon. The latest and best editions of this work are by Backe (Leyden, 1820), with a Latin translation and comments by Balfour; and by C. C. T. Schmidt (Leipzig, 1832).

CLEOMENES, the name of three kings of Sparta, of the Agid line. **I.** Son of Anaxandrides, reigned from about 520 till 491 B. C. Before his accession he was regarded as almost insane; and subsequently he displayed great rashness and cruelty, especially in the burning of Argive captives after the great battle in which 6,000 of his enemies fell. He commanded the Spartans who were sent, in obedience to the repeated oracles of Delphi, to deliver Athens from the tyranny of Hippias (510). He then assisted the party of Isagoras against the Alcæonidæ headed by Clisthenes; but Isagoras, after having banished 700 families from Athens, still more betrayed his ambitious schemes by attempted changes in the senate, and roused the people against himself; the exiles were recalled, and Cleomenes was besieged in the acropolis, and compelled to capitulate. Many years after, accused by his colleague Demaratus of a leaning toward Persia, he bribed the oracle of Del-

phi, and caused the deposition of Demaratus. He was soon banished himself, and went to Thessaly, then to Arcadia, where he incited the people against the Spartans, who, dreading his revenge, permitted him to resume the throne; but on his return the insanity which he had manifested from his earliest life became so violent that he was confined in the stocks, where he committed suicide. **II.** Son of Cleombrotus I. and successor of his brother Agesipolis II., reigned 370-309 B. C. Nothing historically important is recorded of his life. **III.** Son of Leonidas II., reigned 236-220 B. C. He married at an early age the widow of Agis IV., commenced war with the Achæan league, caused the banishment or death of distinguished citizens opposed to his schemes of regeneration, poisoned his infant colleague, and reigned with his own brother Euclidas. He proclaimed the abolition of all debts, relinquished his own property, made a new distribution of the lands, and restored the ancient system of education, the public tables, and other institutions of Lycurgus. The Achæans, attacked and beaten by Cleomenes, invoked the aid of Macedon; and Antigonus Doson entered the Peloponnesus with a large army, and routed the Spartans in the bloody battle of Sellasia. Cleomenes fled to his ally, Ptolemy Euergetes of Egypt, who received him kindly, but soon died, and his son Philopator threw the Spartan king into prison on a charge of conspiracy against his life. He escaped, and killed himself, after a vain attempt to raise an insurrection.

CLEON, an Athenian politician, died in 422 B. C. He was the son of Cleænetus, and a tanner by trade. Endowed with eloquence, he turned his attention to politics, and soon became one of the popular leaders. After the death of Pericles, and for a period of six years, Cleon was the most influential man in Athens. In 427 he persuaded the Athenians to doom the adult males of Mytilene, their revolted ally, to death, and the women and children to slavery; but the vote was rescinded before the edict could be executed. In the "Babylonians" of Aristophanes, represented the next year, Cleon supposed himself assailed, and he retorted by commencing a suit either against the poet or the performer of the caricature; but Cleon himself was brought to trial, and forced to give up a sum of money which he had unfairly obtained from some of the subjects of Athens. These attacks, however, did not shake his power, and he successfully opposed the attempt to grant peace to Sparta, which state was anxiously desirous of bringing the Peloponnesian war to a close when a number of her citizens were shut up in the island of Sphacteria. By the jeers of Nicias and the rest of the peace party, he was induced to take command of the forces at Sphacteria, promising to capture or slay the Spartans within 20 days. His enemies consoled themselves with the belief that he would

fail, and that failure would ruin him. But complete success crowned his labors, and the Spartans were forced to surrender. Although the merit of the military exploit is principally due to Demosthenes, the Athenian general, it is undeniable that Cleon's arrival on the scene of operations infused new spirit into the assailants, whose numbers were overwhelming. His political character was nevertheless bitterly assailed by Aristophanes in his comedies, "The Knights" and "The Wasps." The close of Cleon's career was marked by his mismanagement of an expedition into Macedonia, to operate against the Spartan Brasidas. The Athenians were totally defeated at Amphipolis, Cleon being slain and Brasidas mortally wounded. Cleon is represented by Thucydides and Aristophanes as a mere demagogue; but Grote and others have zealously endeavored to effect a reversal of the unfavorable judgment pronounced against him by his enemies, and by the writers of the aristocratic faction, of which he was the leading opponent.

CLEOPATRA, the last queen of Egypt, third and eldest surviving daughter of King Ptolemy Auletes, born in Alexandria in 69, died there, August 30, 30 B. C. In 51 her father died, and left her by his will the joint heir of the throne with her brother Ptolemy, who was also, according to a not uncommon practice of the Egyptian royal families, to become nominally her husband. Cleopatra was at this time only 17 years of age; but her remarkable precocity, her great talents, and the unbridled ambition of which she already gave unmistakable indications, soon showed the intriguing courtiers who surrounded her and the still younger Ptolemy that so long as she shared the throne they could not hope for that uncontrolled power which they had expected to enjoy on account of the youth and inexperience of the two rulers. Desirous therefore of ridding themselves of the young queen, they succeeded without difficulty in turning her brother against her; and taking advantage of one of the popular riots then frequent in Alexandria, they excited the people by accusing her of scheming for undivided power, and expelled her from the city in the year 49. Pothinus, Ptolemy's guardian, and Achilles, the commander of the army, were the leaders in this movement. Cleopatra at once began preparations for regaining her rights. Rome, where she might have sought aid, as the senate had confirmed her father's will, was in too disturbed a state to answer any appeal, and she attempted none; but collecting her adherents and such forces as she could procure on the Arabian boundary of Egypt, she began to advance upon the country, and prepared for an engagement with the army of Achilles sent against her. In the mean time important events were happening elsewhere. The war between Cæsar and Pompey had been ended by the overwhelming defeat of the latter at Pharsalia (Aug. 9, 48); and the conquered general fled to Egypt, where he

hoped to find a friendly reception, more especially as his party had proclaimed themselves in favor of Ptolemy in his strife against his sister. The treacherous assassination of the Roman leader near Pelusium showed how fatally mistaken was his plan of flight; but the Egyptians failed to gain by his murder the expected end, that of keeping the conqueror away from their country. Pompey had been dead but a few days when the ships of Cæsar appeared in the harbor of Alexandria, early in the month of October. In want of money, and perhaps disposed to interfere in Egyptian affairs, he landed in the city and took up his residence there for the winter months, in spite of the opposition of the people. Several writers even represent him as having been before this attracted by the report of Cleopatra's beauty, which was certainly already famous, and as having prior to his coming received secret agents bringing appeals from her, so that he was even now prejudiced in her favor and ready to embrace her cause; but this is by no means certain. His first act was an impartial one. When he had established himself in the royal palace, suppressing the violent resistance of the Alexandrians, and had the young king entirely in his power, he commanded both the combatants for the throne to lay down their arms and submit the question of their rights to him. Achilles, encamped with his army at Pelusium, refused to obey the order, in spite of the fact that the young Ptolemy was held a virtual prisoner in the city. But Cleopatra at once obeyed, and disbanded her army. She now determined to seek Cæsar in person, and resolved upon the daring venture which forms a celebrated episode in her career. With a single trusted attendant, a Sicilian named Apollodorus, she made her way at twilight, in a little boat, from a larger vessel out at sea, into the harbor of Alexandria, and succeeded in reaching unobserved the steps leading from the royal palace to the water. Wrapped in a roll of heavy carpet tied with cords, she was now carried by Apollodorus into Cæsar's presence. The carpet was unrolled, and the queen, whose beauty at this period of her life must, according to the old historians, have been most brilliant and perfect, appeared for the first time before the astonished Roman. By the added influence of her personal fascination and this daring *coup de théâtre*, Cleopatra's end was gained at once, and from this moment until Cæsar's death her power over him does not appear to have decreased. He now interfered actively, in her interest, in Egyptian affairs, and at first brought about a kind of reconciliation between her and her brother; but this was not lasting, and a complication of intrigues ensued, by which first one and then another of Cleopatra's family endeavored to gain possession of the throne and to drive Cæsar and the queen from the country. A war followed in which Cæsar, cut off in a foreign port, and with only the

troops he had brought with him, was very hard pressed; but he conquered. Ptolemy, who had escaped from the palace to join the Egyptian army, fell in a battle on the Nile near Memphis; and Cleopatra was again made queen, her only surviving brother, a child of six years, being nominally associated with her. The country was now quiet, and the remaining months of Cæsar's life in Egypt were given up to revelry and luxury, which Cleopatra prepared for him with all the resources of her riches and ingenuity; but he was soon compelled to abandon this course of brilliant festivals and the idleness of Alexandria for the East, where Pharnaces, the king of Bosphorus, was in dangerous revolt. He left Egypt in 47, and a few months after his departure Cleopatra bore him a son. Even before his going he had agreed that Cleopatra should go to Rome on his return, and he had no sooner reached that city after conquering Pharnaces than he prepared to carry out the plan. In 46, with her little son Cæsarion, she set sail from Alexandria, and made her entry into Rome with great splendor; ostensibly coming to ask alliance from the senate, but recognized by every one as the acknowledged mistress of Cæsar, who installed her in a palace near the Tiber. Here she held her court like a rightful queen of Rome, flattered by the chief men of the time for the sake of the dictator's favor, but hated by them and by the people, who saw in Cæsar's open relations with a foreign woman a disgrace which Romans felt with special keenness. For a time she seemed to have reached the summit of her ambition, for the dictator treated her with every favor and seemed about to make her his companion in power; when suddenly his assassination (44) destroyed all her hopes and plans at a blow. A short time after the murder she returned to her own capital. During the civil war which followed she preserved a neutral attitude, having much to dread, whichever side conquered. One of her generals, Serapion, assisted Cassius, contrary to her wish, and was afterward punished for his action. Another of her leaders was also induced to join Cassius; but in the main her neutrality was well preserved until the battle of Philippi (42), the event which placed the triumvirate in power, and made Mark Antony the ruler over the East. Cleopatra now saw the necessity for action, and, relying upon the same power of personal fascination that had won Cæsar, she prepared to meet the conqueror. After spending a little time in Athens, Antony had begun a journey into Asia, and had finally established a brilliant court at Tarsus, where the various eastern potentates were already thronging to do him homage. Cleopatra alone did not appear; such a delay as should stimulate Antony's impatience to see her was a part of her plan. For the successful triumvir was not now to meet her, as Cæsar had done under similar circumstances, for the first time. Antony had

seen and admired her in Rome, and she appears to have known that among all the rulers of his eastern dominions, the famous queen was the one for whose coming he was most anxious. Instead of summoning her peremptorily, he sent an ambassador to tell her that she had nothing to fear from him, and to beg that she would visit him at Tarsus; and he followed this message by several letters of the same purport before Cleopatra believed that she had sufficiently aroused his impatience, and at last obeyed (41 B. C.). As he sat enthroned in the market place of the town, it was announced that the Egyptian queen was approaching up the Cydnus, in that splendid progress pictured in sufficiently glowing prose by Plutarch, but made famous for all time by the description of Shakespeare. When Antony sent messengers to ask that she would come to him, she replied that she had hoped to see him first her guest; and the triumvir visited her as soon as she had landed. The beautiful queen's conquest was immediate and complete; with this meeting began that unbridled life of the two lovers that has formed ever since a favorite theme with historians, romancers, and poets; and "from this moment," says Appian, "the before untiring energy of Antony began to grow dull; only that happened which Cleopatra desired, without long inquiry as to what was right and sacred." When Cleopatra returned to Egypt, it was with the promise of another meeting; and Antony, as soon as he could make the most necessary disposition of his troops and his affairs, followed her to Alexandria. The winter of 41-40 passed in revelry of every kind, and only the complications which arose in Rome, and which soon grew too formidable to be neglected, called him from her in the spring. While at the seat of the war against the Parthians, in Asia, he received the news that his party, headed by his wife Fulvia, to whose ambition and desire to distract his thoughts from Cleopatra the outbreak of the conflict in Italy was chiefly due, had been defeated at Perugia. He hastened to Athens on his way westward, and there meeting Fulvia, who had fled thither, he arranged his plans, and sailed for Italy. But the decisive contest was this time averted. Fulvia, left behind in Sicily, and neglected and thrust aside by her husband, died, overwhelmed in grief and anger. A reconciliation between Octavius and Antony was arranged at Brundisium, and the sister of the former, Octavia, became Antony's wife. Cleopatra had now to endure three years of separation from the man whom she thought she had successfully attached to her for life; and we have descriptions from several writers of her rage and jealousy on hearing of his new marriage. But her hold upon him was stronger than she knew. For two winters Antony lived in comparative quiet with Octavia in Athens; the summers were full of activity among the constant complications, quarrels, and reconcilia-

tions of the triumvirate's politics; but in the year 37 the necessity of preparing for another campaign against the Parthians called him again into the East. No sooner was he separated from Octavia than the old love for Cleopatra returned in its full force. Immediately after he had landed on the Syrian coast, he sent a trusted messenger to her, and she hastened to meet him at Laodicea. The old life began again, and, as though to atone for his neglect, he heaped favors upon her, adding province after province to her kingdom, in spite of the complaints of the Romans. Completely reconciled, she returned to Alexandria, while Antony pressed on into Asia, upon his disastrous Parthian expedition. On his return Cleopatra met him on the coast with aid and provisions for his army; and now again he accompanied her to Egypt, and remained there through the next winter, planning a new campaign for the spring. This was more successful, and through it he conquered Armenia. But the decisive struggle with Octavius was not to be longer delayed, and Antony now seemed determined to hurry it on. Returning to Alexandria (34), he celebrated an arrogant triumph, at which Cleopatra was declared a supreme ruler, or "queen of kings;" her son by Cæsar was proclaimed legitimate, a direct attack on Octavius's pretensions to power; and Antony's own sons by Cleopatra were made the possessors of rich Roman provinces. Shortly after this he divorced Octavia, though he did not formally publish the fact till later. He seemed deliberately to attempt to insult the Roman people; yet they looked upon Cleopatra as the author of all that he did, and concentrated their anger upon her. The conflict between Antony and Octavius broke out early in 32, but it only became general when the Roman senate, a little later, declared war, not against Antony, who had passed the previous year with Cleopatra in the old revelries at Ephesus, Samos, and Athens, but against the Egyptian queen herself, who remained by him, aiding his preparations, and urging him to hasten the decisive conflict. The winter of 32-31 passed without event, but in the spring Octavius began with energy those movements which led to the massing of his troops at Actium, and to the decisive battle of the war. Cleopatra seems to have induced Antony, against his better judgment and that of his generals, to take the fatal step of forcing, by an imprudent movement, the engagement at Actium (Sept. 2, 31); but whether she was guilty of positive treachery when, in the midst of the battle, she gave the signal for retreat and set sail for the Egyptian coast, or whether she acted from momentary cowardice, is disputed. Escaping through an opening in the enemy's line of galleys, she made her way to sea, and Antony, abandoning the battle and deserting his troops, sailed after her with all speed to Egypt. All chance of successful resistance to Octavius was now lost; the winter passed away in preparations for de-

fence, in the old life of excesses, and in attempts made by Antony to preserve the allegiance of his troops and generals, many of whom went over to the enemy. Cleopatra seems to have retained her energy, while Antony gave himself up to despair. Many stories of this time are told by ancient authors, in which it is difficult to separate the truth and fiction—of a society, "the companions in death," in which the two revellers gathered their old associates; of Cleopatra's experiments to find the easiest way to die; of Antony's moody withdrawal from all companionship for a time, until he suddenly plunged into greater excesses than ever. In the spring Octavius appeared before the city. The last struggles Antony was able to make were soon over, and both he and Cleopatra seemed about to fall into the hands of the conqueror. As Antony and his troops fled into the city from their last attempt at resistance, the queen gave up all for lost; and hastening to an immense mausoleum she had had constructed some time before, she locked herself in it, accompanied only by two of her women, Iras and Charmian. Antony, returning to the palace, received either at her wish or by accident the report that she had ended her life. Determined not to be separated from her, he attempted to kill himself, but only inflicted a mortal wound. As he lay dying, he heard that Cleopatra lived; he had himself carried to the mausoleum, and there, when the queen and her two women had with great difficulty raised him to the only way of entrance left unclosed, he expired in Cleopatra's arms. Octavius now entered Alexandria. In spite of her precautions, the queen was captured in her mausoleum, and brought before him. He assured her that no harm should befall her; but beyond this she could obtain no intimation in regard to her future fate. The fascination that had conquered Cæsar and Antony had no effect upon him, and after trying all her power of charming, Cleopatra at last saw that she was only allowed to live to grace the conqueror's triumph. She was carefully watched, lest she should put an end to her own life; but she successfully eluded the vigilance of her guards by a skilful device. A countryman bringing her figs brought with them an asp in his basket, and thus furnished her the means of death. Causing Iras and Charmian to array her in her most splendid royal robes and in her crown, she placed the asp in her breast and died from the poison of its bite. Her women imitated her, and the soldiers of Octavius found them lying by her, dead.

CLEPSYDRA (Gr. κλεψύδρα, from κλέπτειν, to steal, and ὕδωρ, water), a hydraulic clock in use among the ancients, which measured time by the quantity of water that escaped from a small orifice in a reservoir. The simplest kind consisted of a transparent vase, filled with water, graduated, and having a small opening in its bottom. As the liquid gradually escaped,

its height in the vase marked the hour. Clepsydras were in use in Egypt under the Ptolemies, and a great improvement in them was made by Ctesibius, a mathematician of Alexandria, about 235 B. C. In his instrument the water was made to drop upon wheels which were thereby turned, and the motion was communicated to a small statue, which gradually rose and pointed with a rod toward the hours marked on a diagram. Clepsydras measured the time allowed for speakers in courts of justice, and they are frequently referred to in the writings of Aristophanes, Aristotle, Plato, Demosthenes, Cicero, and Pliny, like the sands of the hour glass in modern literature. Soon after the decline of Rome they were spread throughout Europe, but their use was abandoned after the invention of pendulum clocks. At the beginning of the 9th century Charlemagne received a magnificent clepsydra as a present from the caliph Haroun al-Rashid. The fact that the quantity of water escaping from the orifice varies according to the height of the column and the shape of the vase furnishes a difficult mathematical problem, which occupied the most skillful geometers of the 18th century. For its solution Bernoulli received a prize from the French academy of sciences.

CLERC, Laurent, a deaf mute, one of the founders and teachers of the asylum for the deaf and dumb at Hartford, Conn., born at La Balme, department of Isère, France, Dec. 26, 1785, died in Hartford, July 18, 1869. In his infancy he fell into the fire, when his head and face were badly burned, and his parents attributed the loss of hearing and smell to this misfortune. At the age of 12 his uncle took him to Paris, and placed him in the institution for the deaf and dumb. The abbé Sicard, though nominally its director, was then in prison for his alleged hostility to the republic; but Jean Massieu, himself a deaf mute, became his teacher till the release of Sicard, when he became a favorite pupil of the abbé, and made such rapid progress that in 1805, after eight years' instruction, he was appointed tutor, and in 1806 a salaried teacher. His aptitude for teaching was such that in a few years the abbé confided to his charge the highest class in the institution, which he taught with great success. In 1815, while on a visit to England, he formed the acquaintance of the Rev. Dr. Gallaudet, whom he accompanied in 1816 to the United States. In 1817 they opened the American asylum for the deaf and dumb at Hartford, and Clerc contributed much to the success of this institution, from which he retired on a pension in 1858, after having been a teacher of deaf mutes for more than 50 years. The greater part of the teachers sent to other institutions for the deaf and dumb from this asylum received their training at his hands. He married in 1819 Miss Boardman, a pupil of the asylum, and like himself a deaf mute. Their children all speak and hear. The eldest son became an Episcopal clergyman.

CLERC, Jean Le. See **LE CLERC.**

CLERFAYT, or Clairfait, François Sébastien Charles Joseph de Croix, count de, an Austrian general, born at Bruille, in the Low Countries, Oct. 14, 1733, died in Vienna, July 18, 1798. He entered the Austrian army at the age of 20, distinguished himself in the seven years' war and in that of the Bavarian succession, and in 1773 became a major general. He was afterward made chamberlain, but rarely showed himself at court, being opposed to the innovations of Joseph II. and to the measures which led to the troubles in the Netherlands in 1787. In 1788-'9, as lieutenant field marshal, he commanded an army corps on the lower Danube, successfully operating against the Turks, who threatened the banat of Temesvár and Transylvania, and subsequently aiding Marshal Laudon in the taking of Belgrade. In 1792 he commanded the Austrian contingent in the war with France, made himself master of Stenai, and compelled the retreat of Dumouriez. After the battle of Jemmapes he conducted the successful retreat to Mons. In 1793 he distinguished himself at Aldenhoven, Maestricht, and Neerwinden, but was defeated at Wattignies. In the campaign of 1794, at the head of a corps of observation in West Flanders, he acted on the defensive against Pichegru, and was repeatedly beaten. Succeeding the prince of Coburg in the chief command in the Austrian Netherlands, he met with new defeats, and was compelled to recross the Rhine. In 1795 he was made field marshal, with command of the troops on the Rhine, defeated Jourdan, and stormed the intrenchments of the French before Mentz, compelling them to raise the siege of that city; and on Dec. 21 he concluded an advantageous armistice with the French republic. He was recalled to Vienna in January, 1796, and honored with the collar of the golden fleece and made councillor of state; but his command was given to the archduke Charles.

CLERGY (Gr. κληρος, lot, portion, heritage), a collective term commonly applied to all persons consecrated to the service of the church, because they are metaphorically said to be the portion or heritage of the Lord, as was the tribe of Levi under the Mosaic dispensation. Some, however, suppose that the term relates to the lot by which Matthias was selected to be an apostle; and others suppose it to be used as a technical term, simply denoting rank or degree. Among the Hebrews, Egyptians, and other ancient nations, a certain class of persons were set aside for the celebration of religious worship, and the Christian church from its very birth had its appointed pastors, or even, as the Roman Catholics and other episcopal denominations hold, its three clerical orders of bishops, priests, and deacons. Although the distinction between clergy and laity was perhaps not so strongly marked at first as it afterward became, the separation of ecclesiastics from ordinary secular affairs, and the appropriation of means for their support, dates from a very

early period. A practice of living in community, like the monks of the present day, appears, from the narrative of St. Luke in the Acts of the Apostles, to have originated with the clergy of Jerusalem; and though interrupted by persecution, it was not entirely abandoned until the distinction was made between secular and regular clergy, when the former ceased to live in communities. It was introduced into various parts of Christendom, and is mentioned by Bede as having been enforced in England by St. Augustin, acting under the orders of Gregory the Great. As the church emerged from poverty, the influence of the clergy became more and more palpable. They were revered not only as spiritual guides and ministers of the sacraments, but as the depositaries of nearly all the learning of the age, so that by the 12th century the term *clericus* became the common designation of every person of education. Civil rulers granted them numerous privileges and exemptions. No bishop could be compelled to appear before a secular court, no presbyter could be interrogated by the torture, no lay tribunal could take cognizance of ecclesiastical matters, nor were the clergy under the Roman empire subject to many of the taxes laid upon the people, or called upon to fill certain public offices. They obtained temporal jurisdiction not only over their own body, but over the laity, and in the German empire the sovereignty of many of the states was vested in them. They thus acquired in the process of time a preponderating influence in European politics, which, however much it may have been at times abused, was unquestionably the only barrier between popular rights and the encroachments of despotic princes, just as in former generations their spiritual influence over the barbarian invaders had saved Europe from slavery. During the middle ages, when the clergy formed a vast, disciplined, and wealthy body, dispersed throughout the known world, each member recognizing his proper superior, and all bowing before the supremacy of the bishop of Rome, this power reached its meridian, though from the days of the first Christian emperors to the most modern times the respective boundaries of secular and ecclesiastical authority have been a subject of contention in nearly every country of the old world. The clergy were anciently subjected to many disciplinary regulations, the chief of which are still in force in the Roman Catholic church, and some of them are observed among Protestant denominations.—In the Roman Catholic church, the ecclesiastical body embraces a hierarchy, which claims to have been instituted by Christ himself, and of which the visible head is the pope. According to the creed of this church, the government of the faithful was committed to St. Peter as the chief of the apostles, from whose successors in the see of Rome all other bishops derive their power to rule. Besides the orders of bishops, priests, deacons, and sub-

deacons, there are inferior officers who fulfil various functions connected with the sanctuary; these are acolytes, lectors, exorcists, and ostiaries, forming degrees by which candidates must ascend to the priesthood. Subdeacons are obliged to take a vow of perpetual celibacy, according to an ancient regulation founded upon a still older custom of the church. It is held that at the introduction of Christianity married men were permitted to take orders on condition of separating from their wives.—In the Greek church there are six orders of clergy, namely: bishop, deacon, subdeacon, lector, cantor, and liturgist. Every secular priest is required to marry a virgin before ordination, but is not allowed to marry a second time; and should his wife die he ceases to exercise the functions of his office, and enters a monastic order. Both Greek and Roman clergy are divided into regular and secular, the former comprising members of religious orders, and the latter all other ecclesiastics. The monks of the first ages were not necessarily connected with the clerical state; but subsequently monks were commonly ordained priests, though partially exempt from episcopal jurisdiction, while their abbots, even if not consecrated bishops, were clothed with episcopal authority, and wore episcopal insignia. The monks of the Greek church are under the same obligation of celibacy as their western brethren.—The church of England recognizes three orders of clergymen, bishops, priests, and deacons, who are comprised in the two provinces of Canterbury and York, each having its archbishop. Each bishopric is divided into archdeaconries, and each archdeaconry into parishes. The last are filled by incumbents who, when possessing the entire tithes of the parish, are styled rectors; when sharing them with lay patrons or cathedral chapters, are termed vicars; and when receiving a stipend from the impropriators of the tithes, bear the title of perpetual curates. Many of the livings are in the gift of laymen. The bishoprics are in the gift of the crown, which nominates a person to be elected by the cathedral chapter, and confirmed by the archbishop. The clergy meet by delegates in convocation at the beginning of every new parliament; though for a long period this practice was disused, the assemblage being regularly dissolved by the archbishop before it could proceed to business. A clergyman is exempt from jury duty, from attendance at a court leet, from arrest in civil suits while celebrating divine service, from filling the office of bailiff, constable, or the like; but, on the other hand, he cannot sit in the house of commons, engage in trade, or farm lands to the extent of more than 80 acres, or for the term of more than seven years. The clerical system of the Protestant Episcopal church in America resembles that of the parent establishment, except in local regulations, and in that it has no archbishops. Some other Protestant communions recognize degrees of

clerical dignity, and lay claim to an apostolic succession, but the majority believe in the ministry of only one order.

CLERGY, Benefit of. See BENEFIT OF CLERGY.

CLERK (Lat. *clericus*, from Gr. *κλήρος*, portion or heritage), the designation of all ecclesiastics in the middle ages. The various usages of the word illustrate the influence exercised by the clergy in the affairs of learning and civil administration. After the barbarism of the northern tribes was transplanted southward, the ecclesiastical order alone retained acquaintance with ancient literature and some of the traditions of ancient scholarship. They were therefore esteemed a learned class, and clerk was synonymous with man of science. At the period of the renaissance it was a complimentary title for men of distinguished learning, even if they were not attached to the priesthood. Most of the high offices were in their hands, since they possessed above others the intelligence requisite for fulfilling them. As learning became more widely diffused, and other classes became qualified to administer affairs, the term clerk was gradually limited to its present signification of an officer in whose duties the keeping of records predominates; and it is now antiquated, except in legal papers, as an appellation of the clergy. Among classes of clerks, in their ecclesiastical capacity, were the *clerici acephali*, who were distinguished from the *clerici canonici* by not uniting in a congregation under the orders of a bishop; the clerks or brothers of common life, a congregation of regular canons which was originated by Gerard Groot of Deventer in the latter part of the 14th century, and spread throughout the Netherlands and Westphalia; and the regular clerks, who lived in community, with or without vows, and formed various congregations, as the Theatines, Barnabites, and Jesuits.—The ministers of France were formerly termed royal clerks and clerks of accounts. A large number of clerkships in the courts and government offices of England were abolished by statutes in 1832 and 1837; but several high officers are still designated by this title, as the clerk of the crown, who attends upon both houses of parliament, and issues writs of summons to peers and judges, and writs for the election of members of the house of commons; the clerk of the house of commons, who endorses the bills and signs the orders of the house, and reads whatever may be required in the course of proceedings; and the clerk of the parliaments, who is the chief ministerial officer of the house of lords, and waits upon the king or queen to receive the royal assent to bills, which he communicates to the lords.

CLERK, John, a British naval tactician, born at Eldin, Scotland, about 1730, died in 1812. He was a country squire who studied naval science, and is said to have disclosed in 1779 his discovery of a new mode of operation for breaking the enemy's line in naval battle, which was successfully applied by Rodney in

his victory over the French under De Grasse in the West Indies, April 12, 1782, and subsequently by other British commanders in many memorable encounters. Sir Howard Douglas, whose father had served under Rodney, contested Clerk's claim to the discovery; and it was asserted by others that Clerk had taken his "Essay on Naval Tactics" (privately circulated in 1782; republished 1790-'98, with additions; new ed., 1804; French translation by Lescahier, 2 vols., 1797) from Father Paul Hoste's *L'Art des armées navales* (Lyons, 1696 and 1727). The fact of his having never been in the naval service, or even at sea, strengthened his opponents; but Clerk's claim to the invention is generally regarded as substantiated.

CLERKE, Charles, an English navigator, born in 1741, died Aug. 22, 1779. He was educated at the naval academy of Portsmouth, and made his first voyage round the world as midshipman under Commodore Byron. In 1768 he sailed round the world a second time, accompanying Capt. Cook in the *Endeavor*, and was raised to the rank of lieutenant. In 1776 he was placed in command of one of the ships which formed the Cook squadron, and on the death of Capt. Cook in 1779 he succeeded to the chief command. The hardships which he was compelled to endure while searching for a passage between Asia and America broke down his health, and he expired off the coast of Kamtchatka, and was buried at Petropavlovsk.

CLERMONT, a S. W. county of Ohio, separated from Kentucky on the S. and S. W. by the Ohio river, touched on the N. W. corner by the Little Miami, and intersected by one of its branches; area, 462 sq. m.; pop. in 1870, 34,268. The soil is fertile, and the surface rolling and hilly. The Marietta and Cincinnati and the Cincinnati and Muskingum Valley railroads touch the N. W. corner. The chief productions in 1870 were 181,532 bushels of wheat, 878,027 of Indian corn, 325,755 of oats, 308,006 of potatoes, 19,535 tons of hay, 769,133 lbs. of butter, 39,425 of wool, and 1,219,762 of tobacco. There were 8,107 horses, 6,837 milch cows, 5,848 other cattle, 12,762 sheep, and 25,028 swine; 8 grist mills, 13 saw mills, 2 distilleries, 24 manufactories of furniture, and 1 of woollen goods. Capital, Batavia.

CLERMONT, or Clermont-Ferrand, a town of Auvergne, France, capital of the department of Puy-du-Dôme, 215 m. S. S. E. of Paris; pop. in 1866, 37,690. It is situated on a hill between the rivers Bedat and Allier, in a mountainous region at the foot of a range of extinct volcanoes, the highest of which is the Puy-de-Dôme mountain. A line of boulevards extends almost round the circuit of the town. In the place de Jaude, the principal square, is a statue of Desaix, and another square is named after the poet Delille, who, like that general, was born near Clermont. Pascal was a native of the town. The W. part of the cathedral, which was greatly damaged during the revolu-

tion, was pulled down in 1855, and has since been in course of restoration. The most ancient church is Notre Dame du Port, of the 11th century, with a modern tower and the statue of a black Virgin, reputed to have miraculous powers. The *palais de faculté* contains several museums and collections, and a public library with 30,000 volumes and curious ancient MSS. In the centre of the Cours Sablon, extending along the east of the town, is a fine fountain. There are two medicinal springs. The most famous, in the suburb of St. Alyre, called *la fontaine pétillante*, issues out of a volcanic tufa resting upon granite. A large stalactite forms a species of bridge, and both fountain and bridge are situated in a garden to which a bath house is attached. The town contains a society for science and fine arts, an academy, a lyceum, a medi-

Cathedral of Clermont.

cal and pharmaceutical school, a normal and a theological seminary, and schools of design, of trades, and of geology and botany. There is an active traffic in agricultural productions, and an important transit trade with Paris and southern France. Silk, linen, cotton, hemp, leather, cutlery, chemical articles, lava ware, and other goods are manufactured. — Under the name of Nemetum or Nemossus, Clermont was the capital of the Arverni, and was enlarged by Augustus, who called it Augustonemetum. Subsequently it was destroyed, and on being rebuilt it received the present designation from the castle of Clarus Mons, which defended the town, and it became the capital of Auvergne, sharing the subsequent fortunes of that province. It is one of the oldest bishoprics of France. The most celebrated of the many ecclesiastical councils held here was that of 1095, when the

first crusade was resolved upon, the badge of the cross worn by the crusaders being first adopted here. Clermont and Montferrand were separate towns till 1633, when they were united by avenues, 2 m. long.

CLERMONT-L'HÉRAULT, or **Clermont-Lodève**, a town of France, in the department of Hérault, 22 m. W. of Montpellier; pop. in 1866, 6,050. Cloth, silks, leather, cutlery, and pottery are manufactured here. The church of St. Guelhelm-le-Desert is a fine Romanesque structure.

CLERMONT-DE-L'OISE, or **Clermont-en-Beauvaisis**, a town of France, in the department of Oise, 35 m. N. of Paris; pop. in 1866, 5,743. It is pleasantly situated on the slope of a hill, and contains, besides a communal college and a public library, three remarkable architectural monuments—an old castle, a hôtel de ville, and the church of St. Samson. The castle has been converted into a prison for females, with about 1,000 inmates. It was a strong fortress between the 10th and 14th centuries, and was taken by the English in 1359 and 1434, and by Henry IV. in 1595. The elder Condé retired hither in 1615. The hôtel de ville was built about 1300, and is an extensive and beautiful edifice, of great interest to architects and antiquaries. It contains among other rare curiosities the funeral monument of a Greek who died in Gaul during the Roman dominion and was buried at Clermont. The church of St. Samson dates from the 14th century, and occupies the highest part of the town. The exterior is very striking, and the interior has a curious altar of carved wood, and other interesting carvings, and some fine paintings. The windows of painted glass are also remarkable. Clermont was the birthplace of King Charles the Fair (1294). It has considerable trade in cattle and horses, and linen and cotton goods and hosiery are manufactured.

CLÉRY, Jean Baptiste, celebrated for his devotion to Louis XVI., and as the faithful valet of the dauphin Louis XVII., born at Jardy, near Versailles, in 1759, died at Hietzing, near Vienna, May 27, 1809. Cléry was one of the few attendants permitted to share the prison of Louis XVI., who a few days before his death divided a loaf of bread with him as the only proof of regard he was able to show him. Cléry published the *Journal de ce qui s'est passé à la tour du Temple pendant la captivité de Louis XVI.* (London, 1798), which passed through many editions.

CLESINGER, Jean Baptiste Auguste, a French sculptor, born in Besançon about 1820. He studied under his father and in Italy, and acquired popularity in 1844 by his bust of Scribe. His subsequent works include a "Girl Bitten by a Serpent," a statue of Louise of Savoy, colossal busts of "Liberty" and "Fraternity," a statue of Rachel as "Phædra," and one of "Tragedy" for the théâtre Français; equestrian statues of Francis I. and of Napoleon I. as Roman emperor, for the Louvre; an admirable figure of a "Gypsy Girl," a bust of

Charlotte Corday; and two statues of Sappho. He has executed many other works relating to classical and mythological subjects. In 1867 he made busts of the emperor of Russia and of the king of Prussia (the present emperor of Germany) for the hôtel de ville, and in 1869 a statue of "Cleopatra in presence of Cæsar." He married the daughter of George Sand.

CLEVELAND, a port of entry and the capital of Cuyahoga co., Ohio, the second city in size and importance in the state, situated on the S. shore of Lake Erie, at the mouth of Cuyahoga river, in lat. 41° 30' N., lon. 81° 46' W., 120 m. N. E. of Columbus, 225 m. N. E. of Cincinnati, and 170 m. S. W. of Buffalo. The growth of Cleveland has been very rapid, the population at the various decennial periods since 1810 having been as follows: in 1810, 57; 1820, 150; 1830, 1,075; 1840, 6,071;

1850, 17,034; 1860, 43,417; 1870, 92,829, of whom 38,815 were foreign born and 1,294 colored. Of the foreigners 15,856 were natives of Germany, 9,964 of Ireland, 4,008 of England, 2,634 of British America, 2,155 of Austria (proper), and 786 of Bohemia. There were 3,562 persons over 10 years of age who could not read, and 4,575 who could not write, of whom 3,748 were foreign. There were 16,182 families, with an average of 5.32 persons to a family. The population is now (1873) estimated at more than 150,000. The city received its first impetus from the completion in 1834 of the Ohio canal, which connects Lake Erie at this point with the Ohio river at Portsmouth. A further stimulus was given after 1850 by the development of the railroad system, and since 1860 its prosperity has been increased by the rapid extension of manufacturing industry.

Cleveland, from the Reservoir.

The greater portion of the city is built on a gravelly plain, elevated from 60 to 100 ft., and overlooking the lake. The river passes through it in a winding course, dividing it into two parts, and affords several miles of dock front. The harbor has been improved by the dredging out of a commodious ship channel, which branches from the river near its mouth, and by the erection of two piers, 200 ft. apart, stretching several hundred feet into the lake. On the E. pier is a lighthouse, and another stands on the cliff above.—Cleveland is laid out with much taste, chiefly in squares. The principal streets are from 80 to 120 ft. wide, Superior street having a width of 132 ft., and are lighted with gas and well paved. The abundance of shade trees, chiefly maple, has given to it the title of the "Forest City." The business blocks are mostly of brick and stone, from

three to five stories high, and a large proportion of the dwellings are of the same materials. Euclid avenue is lined with elegant residences, each surrounded by ample grounds, and is considered the handsomest street in the country. Prospect street, parallel to the avenue, ranks next in beauty. River and Merwin streets, on the E. bank of the Cuyahoga, are occupied by the produce and shipping houses, and by many of the wholesale grocery stores. The jobbing business is principally in Water street, while Superior street is occupied by the larger retail stores, the banks, and the bookstores. The retail grocery, provision, and fruit stores are situated mostly in Ontario street, S. of the public square. This square, known as Monumental park, which occupies 10 acres near the centre of the city, was formerly open to foot passengers only, but since 1866 it has been divided

into four smaller squares by the extension of Superior street from E. to W. and of Ontario street from N. to S. The square is shaded with trees, and is carefully kept. In the N. W. corner there is a handsome fountain; in the S. W., a pool and cascade; in the centre stands a statue of Commodore Perry, the hero of the battle of Lake Erie, erected in 1860 at a cost of \$8,000. The pedestal is of Rhode Island granite 12 ft. high; the statue itself is of Italian marble, and is 8 ft. 2 in. high. In front of the pedestal is a marble medallion, representing the passage of Perry in a small boat from the Lawrence to the Niagara during the battle. West of the river is another park, called the Circle, which has a fountain in the centre, and is finely adorned with shade trees. The city cemetery is on Erie street; it is laid out with rectangular walks, shaded with trees, and contains many tasteful monuments. Woodlawn cemetery, more recently opened, is on the E. boundary of the city. It is prettily laid out, with paths winding among the native trees, and is rich in monuments and statuary. Lake View cemetery, containing 300 acres, 250 ft. above the level of the lake, was opened in 1870, on Euclid avenue, about 5 m. from the city. There is also a Roman Catholic cemetery, and a fifth on the W. side of the city. The water works stand near the lake, W. of the river, and to Jan. 1, 1870, had cost \$798,243 52. By means of a tunnel 5 ft. 2 in. high and 5 ft. wide, extending 6,600 ft. under the lake, pure water is obtained, which is forced by two powerful engines into a large reservoir, occupying the highest point W. of the river, whence it is distributed through the city. The United States building, containing the custom house, post office, and federal courts, the county court house, and the city hall are fine buildings of stone. Case hall, a beautiful edifice near the park, built in 1866, contains, besides the rooms of the Cleveland library association, a hall capable of seating 1,500 persons. The house of correction, on the E. border of the city, is a large and splendid building. The Cleveland medical college occupies an imposing structure on the corner of Erie and St. Clair streets. The city infirmary is five stories high, and cost \$25,000. The union railway depot, a massive stone structure, built in 1866, is one of the largest buildings of the kind in the world. The two high school buildings are handsome edifices of brick and stone, and several of the churches are noteworthy structures. Several bridges cross the Cuyahoga, connecting the different portions of the city, and there are seven street railroad companies.—The steam railroads terminating at or passing through Cleveland are as follows: the Lake Shore and Michigan Southern; Cleveland, Columbus, Cincinnati, and Indianapolis; Atlantic and Great Western (Mahoning division); Cleveland and Pittsburgh; and Cleveland, Mt. Vernon, and Delaware. These roads and the canal connect the city with the coal

fields and grain districts of the state, and the oil region of Pennsylvania, while several lines of steamboats run to the various lake ports. The trade with the Lake Superior mining region is important, and large quantities of copper and iron ore are shipped thence to this port. The trade in wool and lumber is also extensive. The following table exhibits the receipts and shipments of bituminous coal, in tons of 2,000 lbs., from 1865 to 1870:

YEARS.	Received by canal.	Received by rail.	Total receipts.	Shipments.	Consumed at Cleveland.
1865.....	158,112	307,438	460,550	214,837	245,713
1866.....	171,569	404,826	576,395	279,840	296,553
1867.....	125,192	444,814	632,016	324,027	297,989
1868.....	197,475	547,964	745,439	392,388	353,051
1869.....	225,401	655,211	910,621	396,067	524,555
1870.....	120,000	774,000	894,000	482,390	411,610

The trade in anthracite coal amounts to about 10,000 tons per annum. The foreign trade is exclusively with Canada. The imports for the year ending June 30, 1872, amounted to \$584,576; the exports were valued at \$893,172. There were entered from foreign countries 312 American vessels, of 86,753 tons, and 252 foreign vessels, of 46,479 tons; cleared for foreign ports, 274 American vessels, of 52,693 tons, and 269 foreign vessels, of 47,316 tons; entered in the coastwise trade, 599 steamers, of 395,174 tons, and 2,289 sailing vessels, of 450,501 tons; cleared, 590 steamers, of 396,618 tons, and 2,333 sailing vessels, of 467,234 tons. The total number of vessels cleared in 1863 was 3,109, with an aggregate tonnage of 1,112,696; in 1872, 3,466, with an aggregate tonnage of 963,861. In the latter year there were registered, enrolled, and licensed at this port 446 vessels, of 66,013 tons, including 181 sailing vessels of 40,076 tons, 60 steamers of 15,294 tons, 201 canal boats of 10,173 tons, and four barges of 469 tons. There were built during the year 5 sailing vessels of 2,229 tons, and 2 steamers of 1,598 tons.—The manufactures, particularly of iron and coal oil, are very important. In the production of refined petroleum the city is second only to Pittsburgh. Other important products are sulphuric acid, wooden ware, agricultural implements, marble and stone, grindstones, railroad cars, and white lead. Pork packing is also carried on to some extent, 36,415 hogs having been packed during the season of 1870-'71, and 35,010 in 1871-'2. There are 50 incorporated companies (chiefly manufacturing), of which 38 have an aggregate capital of \$11,690,000. According to the census of 1870 there were 1,149 manufacturing establishments in Cuyahoga county, most of them in Cleveland; steam engines, 274, of 9,388 horse power; water wheels, 55, of 2,179 horse power; hands employed, 10,063; capital invested, \$13,645,018; wages paid, \$4,539,065; value of materials, \$16,861,357; of products, \$27,049,012. The following table exhibits the principal manufactures:

ARTICLES.	No. of estab- lishments.	Capital.	Value of Products.
Agricultural implements.....	3	\$259,000	\$145,500
Boats.....	9	141,800	257,860
Boots and shoes.....	9	67,200	202,292
Bread, &c.....	26	79,700	283,114
Breweries.....	25	449,500	511,050
Brick.....	23	42,800	113,700
Bridge-building.....	2	175,000	536,000
Cheese.....	14	40,450	202,565
Clothing.....	77	211,105	583,389
Coal oil, rectified.....	16	520,000	4,283,065
Coffee and spices, ground.....	3	160,700	207,500
Cooperage.....	63	233,700	1,051,785
Edge tools and axes.....	2	88,000	96,000
Flour mills.....	13	744,500	1,903,155
Furniture.....	29	291,400	505,975
Gas.....	1	525,000	232,792
Gunpowder.....	1	150,000	165,000
Iron, forged and rolled.....	8	1,190,000	2,290,784
" bolts, nuts, &c.....	3	175,000	222,000
" nails and spikes, cut, &c.....	3	65,150	127,450
" pipe, wrought.....	2	47,500	169,000
" pigs.....	2	120,000	398,000
" castings (not specified).....	12	803,000	1,097,000
" stoves, heaters, &c.....	4	355,000	270,000
Leather, tanned.....	10	63,400	173,844
" curried.....	9	48,200	115,814
Lightning rods.....	1	150,000	150,000
Lime.....	3	36,700	85,400
Lumber, planed.....	7	69,000	183,300
" sawed.....	32	80,900	170,512
" staves, shooks, &c.....	2	3,500	132,400
Machinery (not specified).....	14	150,100	173,445
" railroad repairing.....	3	1,225,000	997,070
" engines and boilers.....	11	159,300	406,300
Malt.....	5	331,500	282,500
Matches.....	1	250,000	110,000
Paints.....	4	185,000	244,400
Paper.....	3	390,000	531,175
Pianos.....	3	81,000	113,530
Fork, packed.....	4	195,800	1,195,570
Printing, newspaper.....	9	91,500	151,740
" job.....	5	54,500	113,550
Saddlery and harness.....	33	41,330	113,406
Sashes, doors, and blinds.....	3	314,500	344,500
Sewing machines.....	2	46,000	230,000
Steel springs.....	1	70,000	100,000
Sulphuric acid.....	2	32,000	63,800
Tin, copper, and sheet-iron ware.....	50	108,460	234,495
Tobacco and snuff.....	2	60,000	337,000
" cigars.....	52	118,250	450,896
Tombstones.....	5	159,400	325,500
Wagons.....	47	162,200	264,296
Wooden ware.....	3	324,000	337,500
Woollen goods.....	3	251,000	211,100

Cleveland contains 6 national banks, with an aggregate capital of \$4,300,000, 2 savings banks, and 9 insurance companies (2 life), with a capital of \$1,950,000. There are 31 hotels and 3 markets.—The city is divided into 17 wards, and is governed by a mayor and common council of two members from each ward. There are also a clerk, who is likewise clerk of the common council, an auditor, a treasurer, a solicitor, a street commissioner, a civil engineer, and a superintendent of markets. The board of improvements consists of the mayor, street commissioner, engineer, a clerk, and two other members; the board of health is composed of the mayor, health officer, and six others. The United States circuit and district courts for the northern district of Ohio are held here; also the state district court, the court of common pleas, a probate and a police court. The board of metropolitan police consists of the mayor, a secretary, and a superintendent. The city is

divided into 5 precincts, and the force, besides the privates, is composed of a captain, 6 sergeants, 3 acting sergeants, 3 detectives, and 3 special detectives. The fire department is under the control of a chief engineer and 2 assistants. There are 7 steam engines, 2 hook and ladder companies, and a fire alarm telegraph, under the charge of a superintendent. The assessed value of property in 1870 was \$51,841,746.—There are several well conducted reformatory and charitable institutions. The house of correction is under the charge of a board of directors. The city infirmary, to which the sick and homeless poor are taken, has attached to it a good farm, which is worked by the inmates of the institution. Connected with the infirmary is a house of refuge for children, where they are instructed and taken care of until of an age to maintain themselves. St. Vincent's male orphan asylum contains 150 orphans under the charge of the sisters of charity, and St. Mary's female orphan asylum, under the charge of the ladies of the Sacred Heart of Mary, has 160 inmates. The "little sisters of the poor" provide for 70 aged men and women. The Cleveland orphan asylum is supported by voluntary contributions, and by an endowment fund of about \$54,000. The Episcopalians have a home for sick and friendless widows, and the Jews support an orphan asylum. A United States marine hospital has been established here, and is situated on the border of the lake. The charity hospital, established partly by the city and partly by subscriptions, is attended by the sisters of charity. There are also a homoeopathic hospital and a city hospital. In the industrial school poor and homeless children are provided with food and shelter, and are taught the common branches of education, sewing, domestic labor, and brush making. The public schools are under the control of a superintendent and a board of education of one member from each ward, and consist of 2 high schools and 16 grammar and primary schools. The average attendance of pupils in 1871 was 8,175, of whom 4,133 were males and 4,042 females, the number of teachers was 187, of whom 9 were males; the receipts were \$145,049 67 from taxation, and \$48,457 69 from the state fund; expenditures, \$143,700 95, of which \$118,655 were for teachers' wages and \$27,880 69 for sites and buildings. The Cleveland female seminary had 13 instructors, 100 pupils, and a library of 1,000 volumes; the Union business college had 6 teachers and 448 pupils. There are two German and English schools, 7 other seminaries and schools belonging to Protestant societies, 11 Roman Catholic academies and schools, and 6 private and select schools. The Ohio State and Union law college in 1871 had 2 professors, 28 students, and a library of 2,500 volumes. The Cleveland medical college (medical department of the Western Reserve college at Hudson) and the medical department of the uni-

versity of Wooster are situated here. The homeopathic hospital college, founded in 1849, which admits females, in 1871 had 17 professors, 86 students, and a library of 2,000 volumes. St. Mary's ecclesiastical seminary (Roman Catholic) has 3 professors and 25 students. The Western Reserve historical society has its seat here. The Cleveland library association have a reading room and a library of 12,000 or 15,000 volumes. The public library, opened in 1869, contains about 8,500 volumes. There are 6 daily newspapers (1 German), 3 tri-weekly, 1 semi-weekly (German), 10 weekly (2 German and 1 Bohemian), and 1 semi-monthly and 7 monthly periodicals. The principal place for dramatic entertainments is the academy of music, besides which there are a Bohemian theatre, a German theatre, a theatre comique, and various other public halls for lectures, &c. The freemasons have 2 halls and 13 lodges, chapters, &c., of which 1 is for Germans; the odd fellows have a hall, 2 encampments, and 10 lodges (2 German). There are 10 temperance societies, and 25 lodges, &c., of other orders. The city contains 88 churches, divided as follows: 7 Baptist (1 German and 1 colored), 1 Bible Christian, 13 Roman Catholic (1 Bohemian, 1 French, and 4 German), 1 Christian, 5 Congregational (1 colored), 1 Disciples', 2 Evangelical (German), 4 Evangelical Association (3 German), 2 Evangelical Lutheran (German), 2 Evangelical Protestant (1 German), 1 Free Will Baptist, 1 Friends', 2 Jewish, 15 Methodist (2 German and 1 colored), 7 Presbyterian, 11 Episcopal, 4 Reformed (3 German), 1 Spiritualist, 1 Swedenborgian, 1 Unitarian, 3 United Evangelical (1 German), 1 United Brethren (German), 1 Universalist, and 1 miscellaneous. There are a young men's Christian association, a women's Christian association, 2 convents, and 2 other Catholic religious associations.—Cleveland was laid out in 1796, and was named in honor of Gen. Moses Cleaveland, a native of Connecticut, under whose charge the first surveys in what is known as the Western Reserve were made. It was until 1806 confined to the E. shore of the Cuyahoga, and was an important strategic point in the war of 1812. A portion of what is now the city of Cleveland was incorporated as a village in 1814. A city charter was granted in 1836.

CLEVELAND, Charles Dexter, an American author, born at Salem, Mass., Dec. 3, 1802, died in Philadelphia, Aug. 18, 1869. He graduated at Dartmouth college in 1827, and was professor of Latin and Greek at Dickinson college, and afterward of Latin in the university of New York, till 1834. He then taught a school for young ladies in Philadelphia till 1861, when he was appointed United States consul at Cardiff, Wales. He published "The Moral Characters of Theophrastus" (1827), "Compendium of Grecian Antiquities" (1828), "Compendium of English Literature" (1850), "Hymns for Schools" (1850), "English Literature of the Nineteenth Century" (1851), a critical

edition of "Milton's Poetical Works" (1853), "Compendium of American Literature" (1858), "Compendium of Classical Literature" (1861), and "Lyra Americana" (1868).

CLEVELAND, Henry Russell, an American author, born in Boston in 1809, died in St. Louis, June 12, 1843. He graduated at Harvard college in 1827, prepared an edition of Sallust, wrote "The Life of Henry Hudson" in Sparks's "American Biography," and was a frequent contributor to literary periodicals. A collection of his writings, edited by G. S. Hillard, has been published (Boston, 1844).

CLEVENGER, Shobal Vail, an American sculptor, born at Middletown, Ohio, in 1812, died at sea, Sept. 28, 1843. In his youth he worked as a stonecutter in Cincinnati, where the figure of an angel which he carved on a tomb attracted attention. From Cincinnati he removed to Boston, where he executed busts of Webster, Clay, Van Buren, and others. He afterward went to Europe, taking up his residence at Florence, where he executed many busts, which showed a rapid advance, and gave promise that he would attain the first rank in his profession. Having been attacked by pulmonary consumption, he embarked for America, but died on the passage.

CLEVES (Ger. *Kleve* or *Cleve*), a town of Rhenish Prussia, in the district and 48 m. N. W. of the city of Düsseldorf, about 4 m. from the Dutch frontier and the Rhine; pop. in 1871, 9,038. It is built upon three gently sloping hills, in a fertile region with extensive valleys and woodlands, which in the 17th century were converted into pleasure grounds by Prince John Maurice of Nassau-Siegen, whose iron tomb is near the town. The mineral spring in the Thiergarten was restored in 1846, and a drinking hall and bath house were added in 1847. The castle of Schwandenburg, the former ducal residence, and the birthplace of Anne of Cleves, the fourth wife of Henry VIII. of England, is famous for its picturesque tower, said to have been built by Cæsar. It is now used as a prison and for public offices. Among the other public buildings are the Prinzenhof, belonging to the princess of Waldeck; a Roman Catholic church, with monuments of the counts of Cleves; and places of worship for Protestants, Mennonites, and Jews. There are several schools and a gymnasium, and a monument of the elector of Brandenburg, John Sigismund, by Bayerle. It is connected with the Rhine by a canal, and by railway with other parts of Germany and with Holland. There are manufactories of cotton, leather, and tobacco.—Cleves was formerly the capital of a county, and subsequently of a duchy, which formed part of the Westphalian circle of the German empire, and in 1609 fell to Brandenburg, with the exception of a portion annexed to Neuburg. By the treaty of Lunéville (1801) a part of the duchy was ceded to France, and a part was in 1806 incorporated with the grand duchy of Berg. In 1815 the whole was restored to Prus-

sia, except some districts on the Maas, and a few villages which were claimed by Holland.

CLIENT (Lat. *cliens*, according to some from an old Latin verb, *cluere*, to obey), in Roman antiquity, a man of inferior class, or lower situation, connected for mutual service and obligation with a citizen of better standing, in this relation called patron (*patronus*), or protector. This relation of client and patron (*clientela*), which seems to have been of great historical importance in the first centuries of the Roman state, is said to have been introduced by Romulus, in order to form a social link connecting the two separate and naturally antagonistic bodies of Roman society, the patricians and the plebeians. Some even believe that at the earliest period of Roman history the names patricians and patrons were identical, and that the clients embraced the whole bulk of the plebs. But this supposition, though founded on testimony of ancient date, can hardly be proved, the history of this institution in general being involved in great obscurity. According to Dionysius, whose history contains a summary of the mutual obligations of clients and patrons, together with a historical sketch of the institution, both of doubtful accuracy, the patron was the legal adviser and paternal protector of the client, and bound to assist him in need or danger; the client was bound to filial respect and reciprocal assistance, to contribute to the portion of the patron's daughters in case he became poor, to ransom him if made captive, and to vote for him or his friends when standing for office. The client and patron were not allowed to sue or to bear witness against each other, and had religiously to abstain from any injury to each other. The client accompanied his patron in war, being in this respect similar to the vassal of the middle ages, and bore his family name, partaking in the sacrifices and sepulchre of the *gens* with which he was thus associated. If he died without an heir, his patron (according to Niebuhr) inherited his property. The wife of the latter was the *matrona* or patroness of the protected family. Illustrious families found their pride in the number of their clients, and strove to gain new ones, the relation being hereditary. Freedmen became natural clients. It is stated that Romulus, regarding the connection as a religious tie, and an infringement upon its duties as a sacrilegious act, bestowed upon clients the right of unlimited self-defence against tyrannical patrons, but this can hardly be accepted. Whatever the original condition of the clients may have been, their situation was made more favorable by the constitution of Servius Tullius, admitting the plebeians to a regular share in the political affairs of the state. Though greatly modified in the course of time, the institution maintained itself down to the period of the emperors. Foreigners also often stood under the protection of distinguished Roman citizens, chosen as patrons. Even foreign states which were in alliance with Rome had their patrons

in the capital of the mighty republic, and the senate often referred the decision of international disputes to the respective patrons. Similar institutions are said to have existed at an early age among other nations of Italy, as well as among some tribes of Thessaly.—In modern usage the term client designates a person who commits his legal cause to a lawyer or counsellor.

CLIFTON, a watering place of Gloucestershire, England, now forming a suburb of Bristol; pop. in 1871, 20,701. It is built on the southern acclivity of a steep cliff, nearly at the top of which is York crescent, a fine row of houses. Above this are Clifton down and St. Vincent rocks, 300 ft. high, crowned by an observatory. In some places the rock rises perpendicularly, and the Avon flows through a deep gorge, which is crossed by a suspension bridge of 702 ft. span and 260 ft. above the river. The bridge was built after designs by

Clifton Suspension Bridge.

Brunel, and partly from funds left by Alderman Vick in 1753; but owing to lack of money it was long in an unfinished state, and was not completed till 1864. Clifton is the seat of a Roman Catholic bishop, and near it is Stapleton, the palace of the Anglican bishop of Gloucester and Bristol. Clifton college occupies an area of 15 acres, and comprises a gymnasium, boarding houses, schools, and chapels. There is a fine zoological garden. The scenery of the neighborhood is romantic. The hot spring, situated at the foot of St. Vincent rocks, has a temperature of 76° F., and discharges about 40 gallons a minute. The principal mineral ingredients of the water are salts of lime, and when it is drawn into a glass a few bubbles of carbonic acid gas are emitted. The water is useful in many disorders. The spring has been known for centuries, but was first enclosed by the corporation of Bristol in 1690. There are now a pump room and hot and cold baths. The climate is salubrious, though strong winds prevail from the west and southwest. Rain frequently falls, but owing to the absorbent nature of the soil the ground soon dries.

CLIMATE (Gr. *κλίμα*, Fr. *climat*), the condition of any portion of the earth's surface in respect to temperature, moisture, and other atmospheric phenomena. The Greek original (from *κλίειν*, to slope or incline) was employed to signify the obliquity of the sphere, to which the inequality of the length of the day was due, the word primarily signifying an inclined plane or slope; hence applied to a belt or zone of the earth's surface differing, for the reason above given, from another or contiguous belt in the length of its day. The geographer Ptolemy was the first to establish these belts and to define them as climates; dividing the surface from the equator to the 58th parallel into 25 such climates, differing a quarter of an hour each in the length of the longest day; next from the 58th to the 63d parallel making four climates of one half hour's difference each, and from the 63d to the 66th parallel three climates of one hour each. From the polar circle to the pole there were six climates of one month's difference each. At the equator the first belt was 4° 15' in width, diminishing gradually till at the 45th parallel it was 1° 50' in width, and at the 57th parallel 30' only. This irregular and fanciful division long remained, in consequence of the difficulty of attaining to any positive basis of distinction on astronomical or purely geographical grounds. As discoveries extended in all directions, and particularly to western Europe, distinctions founded on latitude or length of the day were found to be inapplicable and valueless, and they fell into disuse long before observation began with the instruments now in use to measure the heat, the weight of the air, &c. With the invention of these instruments the word climate came to signify the aggregate of atmospheric conditions affecting organic existence, animal and vegetable; and particularly the degree of heat, the winds, the rain, the changes in atmospheric weight, and all like sensible conditions. The barometer, developed from the Torricellian vacuum in 1643, was the first instrument suited to exact observation; soon afterward expandible fluids were used as measures of heat, and good spirit thermometers were in use in 1680. But it was not till 1730 that mercury was substituted for spirit in part, and permanent series of observations began to be recorded; the first in America being at Charleston by the learned Dr. Lining in 1738. Great activity existed near the close of the 17th century, when these instruments were novel, and when positive and even mathematical precision was hoped for through records of their observation; and the earlier "Philosophical Transactions" of the royal society are full of papers and discussions on the subject. But it was soon found that there was no parallel in this to other departments of physics, and interest in it greatly declined until the new and broad generalizations of Humboldt were put forth. To Sir William Herschel and Alexander von Humboldt the world is chiefly indebted for the rapid progress

made in the science of climatology within the present century. Humboldt in 1817 published his celebrated treatise entitled *Des lignes isothermes, et de la distribution de la chaleur sur le globe*, in which he showed that the decrease of heat with the increase of latitude takes place more slowly on the west coasts of the old world than on the east of the new. He connected places having an average amount of temperature during the year by isothermal lines, the convex summits of which fell near the west coast of the old world, and their concave near the east coast of the new. By combining the decrease of temperature by increasing elevation with its decrease by increasing latitude, he represented the intersection of isothermal surfaces with a vertical plane cutting the surface of the earth along a meridian, and showed that if the examination of places of equal summer heat and equal winter cold were conducted in a similar manner by drawing isothermal and isochimal lines, the difference between a sea and a continental climate would be included in the general view. These isothermal lines differ materially from the parallels of latitude. It is not necessary to enter into detail as to how the annual rotation and oblique motion of the earth in relation to the sun fix the tropical limits of the sun's apparent declination south and north of the equator, and produce alternate winter and summer on either side of the line, as it will be evident that the mean annual temperature obtained at different latitudes must decrease from the equator to the poles. Had the whole surface of the earth been uniform, presenting the like relations to radiant heat, unaffected by the unequal action of disturbing causes, the mean temperature of every point would have been in proportion to the radius of the parallel of latitude. But the mean temperature of places in the same lines of latitude differs very materially. The isothermal line, for example, of 59° F. traverses latitude 42° in Europe, but descends to latitude 35° in America. Hence it appears that the mean annual temperature in the latitude of Beaufort, N. C., 34° 41', is nearly the same as that of Rome in latitude 41° 54'; and it consequently follows that other causes are in operation in both of these different localities affecting the mean temperature than nearness to or remoteness from the equator. Accurate and long continued observations are necessary to give value to meteorological facts. These have been pursued of late with much zeal. Kämtz and Muhlman have carefully represented annual isothermal lines, but Professor Dove was the first to reduce these to monthly temperatures. The observations of Professor Dove were first published in the "Transactions of the Royal Academy of Sciences" in Berlin, in 1846, and have since appeared in the "Transactions of the British Association." These observations, which are of great value, and place their author among the first of living meteorologists, fully sustain the views of Humboldt, and natu-

rally lead to an examination of the physical formation of the earth, as a cause of this great discrepancy in climate in the same parallels of latitude. According to Malte-Brun, climate is the assemblage of all those external physical and natural circumstances connected with each particular locality, which have a bearing upon the modifications of its temperature. This definition, adopted by M. Virey in the *Dictionnaire des sciences médicales*, and by M. Foissac in his work entitled *De l'influence des climats sur l'homme*, is susceptible of embracing all those phenomena involved in the complex study of physical climate, which are so varied in character, and frequently so little allied to each other, as to forbid their exact and rigorous classification. —The actual climates of the earth, as practically experienced by its living forms, animal and vegetable, are greatly diversified and highly irregular. The averages or fixed quantities for different latitudes and localities are widely variable, and the non-periodic range of the leading conditions is even more extreme. The causes of this marked exception to the otherwise well defined character of all movements of matter, and the reason why this department of physics cannot, in the present state of knowledge at least, and probably not at any time, be the subject of precise analysis, may be seen from the following general statement. It is already admitted as certain that the various climates cannot be defined by any astronomical conditions, or by the form and movements of the earth relatively to the sun. Yet the heat received from the sun is the fundamental condition and controlling cause in all cases, and it acts both directly and through the secondary agencies of aëriiform fluids and all mobile forms of matter. That is, the heat of the sun's rays is one part of the supply, as those rays fall direct on the surface, while air, atmospheric vapor, and water are also powerful agents in receiving and diffusing heat, bringing the direct product of the sun's power, as received in the tropics, far northward to soften the climates which cannot receive sufficient heat directly. The power of this tropical heat is enormous. Not only are animal and vegetable forms stimulated by it to their largest growth, but the whole inorganic mass capable of motion is put in active circulation. By this heat the air is rarefied and given rapidity of circulation, at the same time that vast volumes of water are converted into vapor, capable of absorption and diffusion almost throughout the entire aërial mass. This system of air and water circulation causes, as one general result, the evaporation and subsequent precipitation in rain of a sheet of water that may be stated as being ten feet deep at the equator, six feet deep on the average in the tropics, three feet deep at the 45th parallel, and one foot deep or less at the Arctic circle. This vapor, being raised by heat, is precipitated in rain as the heat is dissipated; and this absorption and diffusion are

also concurrent with a systematic movement of the aëriiform mass, a movement which in the tropics is against the rotary movement of the solid mass of the earth, and probably is due in part to simple retardation of these fluid volumes, relatively to this solid portion. An inward and upward movement within the tropics, consequent upon this heat and saturation, originates the great system of atmospheric circulation, and distributes to the temperate latitudes most of the moisture there deposited. A surplus of heat is also so diffused, and through these joint agencies the actual climates of a large portion of the earth's surface are established. And as the middle or temperate latitudes are in the direct path of the returning atmospheric current, the more striking general phenomena these climates present are easily explained in this connection. In passing northward and descending to the surface, these volumes of heated and saturated air lose their surplus of heat and most of their contained moisture; and in moving from west to east in these latitudes this circulation brings mild temperatures and local humidity from any ocean surface traversed; hence the profuse rains and moderate heats of the western coasts of both continents. In the interior, the same circulation continuing, there are alternations of both conditions; the heat being greater in the season of greatest heat and less in the cold season than on the coasts, and the rains being alternately profuse and deficient. The degree of these alternations is increased until the immediate eastern boundary of the continents is reached, when a limited and local maritime influence appears to neutralize the agencies prevailing on the interior surface. Climates distinctly maritime, or directly controlled by adjacent water surfaces, exist in but few positions on the eastern borders of the continents. At Norfolk, Newport, Nova Scotia, and Newfoundland on the Atlantic coast, there are quite decisive maritime influences—particularly at or near Newport, and over most of the Nova Scotian peninsula; but these are due to unusual exposure, and close proximity to the Gulf stream.—Next to the atmospheric circulation in its influence on the actual distribution of heat is the movement of great sea currents. These currents are caused by the same tropical excess of heat, with its consequent rarefaction of the fluid mass of the equatorial latitudes. A movement westward within the tropics is arrested by the continental masses of both America and Asia, and deflected in the gulf of Mexico and on the coast of China, forming the Gulf stream of the Atlantic and the Kuro Siwo of Japan and the Pacific. These great currents move northward on the surface of vast seas, diffusing their excess of heat, and greatly modifying the climate of the land surfaces within their reach. This agency is especially powerful on the western coast and islands of Europe, deflecting the atmospheric circulation itself, charging the air with hu-

midity, and rendering the general climate exceptional in the highest degree. Also in the Pacific ocean the agency of the Japan current is very great in bearing heat and moisture to higher latitudes than they otherwise would go. The western coast of America, from San Francisco to Behring strait, is bathed in this warm and softening influence, receiving much more of both heat and its attendant conditions than the atmospheric circulation alone would bring. In the southern hemisphere a similar but less powerful movement of the sea currents attends the atmospheric circulation, with consequences generally similar in modifying the climate of the land surfaces, but less striking and important. There are also in both hemispheres returning cold currents of much local importance, affecting the climate of certain tracts on the immediate coasts. The most important of these is the cold deep-sea current of the Pacific ocean, which, returning southeastward from the northern areas of that sea beneath a warm surface current, impinges on the W. coast of North America, and rises to the surface from the mouth of the Columbia river to Monterey, giving rise to the extraordinary cold day winds of summer at San Francisco, and over a long line of that coast. This very striking fact finds no solution in any general theory of distribution of heat, either as received direct from the sun or as modified by atmospheric circulation, with its attendant standards of maritime and continental influences. It is due solely to the aqueous circulation, in a phase unknown to the eastern continent. As the result of this great diversity of controlling influences, there can be no determination of the leading conditions of climate otherwise than by observation. Even with certain standards for the equatorial belt and for the poles, as has sometimes been assumed, there can be no formula for interpolating the measures of heat or of humidity for the intervening latitudes; and observation must be continued for a period sufficient to cover the average of non-periodic variations above and below a true mean. These non-periodic changes are very great, and both in their degree and origin are in the present state of knowledge to a great extent inexplicable. An average for ten years is, however, nearly sufficient to give a true mean or fixed quantity in any of the conditions: the temperature, the fall of rain, and the date of significant changes, as the freezing or opening of rivers, the opening and closing of the season for growth of plants, &c. Observation of the leading conditions of climate has made great progress within the past half century, and a remarkable degree of continuous and faithful attention to the record of such observations has been shown by citizens and public institutions in the United States since 1820, while valuable and almost continuous series exist for some localities for a long time previous to that date, the earliest having been begun in 1738. In Europe the records of instrumental observation are but lit-

tle more extended, the earliest being about 1720.—Anterior to the discovery of instruments suited to measure the degree of heat, the weight of the atmosphere, &c., the tone of speculation and discussion of climatological laws was very loose, and full of highly imaginative views and conjectures. With the invention of the thermometer and barometer a new impetus was given to the study of climatological physics, and a vigorous attempt was made to apply positive measurements and to discover absolute laws. But it soon became apparent that the range of non-periodic phenomena was too great, and that the differences were too striking which were disclosed in the comparison of localities which should, so far as could be seen, very nearly agree, to admit of calculation on recognized physical laws. A long period then elapsed in mere waiting for the requisite basis of observed facts on which a legitimate and safe induction could be founded, and this period had not closed when Humboldt published his striking and effective generalizations, a system of illustration of the distribution of heat by isothermal lines. Time has not yet been afforded for the accumulation of observations of sufficiently extended periods over more than a small portion of the earth's surface, and it is not possible yet to fix the distribution of heat with accuracy over any considerable part of the southern hemisphere. But the general outline of a positive climatology put forth in Humboldt's treatise has been greatly extended and filled up by subsequent labors, until it has attained a fixed position among scientific determinations. The leading condition determined is the mean temperature; next to that is the average rainfall, and next the resultant or average direction of the winds. The barometric measurements have been equally well established; and also the range or measurement of departure of each of these conditions from the mean, both periodic and non-periodic. The hygrometric condition, or the proportion of suspended moisture in the air, has been less generally observed, but it is recognized as a necessity in the proper definition of climates. For all these the periods of observation in many parts of Europe and of the United States are ample, covering, as has already been said, more than a century at a few stations. But the necessity for a wide distribution of observed positions delays the most important of the uses to which these observations may be put. We turn, therefore, from the discussion of the ultimate laws concerning the principal conditions of climate, to the consideration of the remarkable facts of actual climate in the countries where determinations are recent. In the eastern part of the United States the facts have been long known, but in the interior and the west much is new. While the refrigeration originating with the mere presence of great continental areas is great, and develops a continual series of violent alternations of temperature over much of the surface in the

entire valley of the Mississippi, there is a novel change apparent in going westward to the foot of the Rocky mountains, the degree of heat increasing not only relatively but positively, being greater at considerable altitudes of the great central plateaus than on the Atlantic coast in the same latitudes. Thus at Fort Benton, Virginia City, Laramie, and Denver, points at various altitudes from 2,500 to 6,000 ft. above the sea, at the eastern foot of the Rocky mountains, the climate is milder than at sea level on the Atlantic coast in the same latitudes. At Fort Benton, on the upper Missouri, lat. $47^{\circ} 50'$, and 2,700 ft. above the sea, the mean is 10° warmer than at St. John's, Newfoundland, nearly in the same latitude. At Fort Laramie, 4,500 ft. above the sea, it is warmer by 2° or 3° in the annual mean than at Boston, nearly in the same latitude. Denver, at 6,000 ft. above the sea, is as warm as Baltimore, which is in the same latitude. These are representative positions for a large mass of interior surface, on which the climate is in marked contrast with the usual standards for like elevations, and where also the special modifying influences of the Pacific do not reach. A like anomaly exists on the great plateaus of central Asia, which has been noticed by Humboldt, and was recognized by him as establishing a new form of continental influence, or that of increased heat due to the presence of great elevated areas. Again, of new and striking developments in the climates of the western coast of North America, there are illustrations in the abrupt contrasts of the immediate coast of the Pacific with the interior, especially in summer. The peculiar cold winds of that coast in summer are met with off the coast before reaching the 30th parallel, and they are severe and almost violent from lat. 35° to 45° N., or almost to the mouth of the Columbia. They are due, as has been stated, to the vast mass of cold water moving from the northwest as a deep-sea current, and rising to the surface on the immediate coast. The highly heated plains and basins of the interior cause great rarefaction of the air in those basins, toward which the colder mass of the coast is drawn with force during the day, to subside in calm at night when radiation has cooled the temperature and restored the equilibrium. Further north the sea is warmer, both positively and relatively, and no contrast exists with the temperature of the land. The summer is very warm, and the climate most prolific in both animal and vegetable life over all Alaska and the broad valley of the Yukon, to lat. 65° or 68° N. Here again are marked contrasts of the Yukon and Mackenzie river valleys with the great plains eastward to Hudson bay. On this tract, and still more eastward and northward of this bay, the maximum of continental refrigeration exists, and a summer is scarcely known. The extreme severity of the climate of this district, down to the lower border of Labrador, is in marked contrast with the cli-

mate of like areas of Asia, rendering it less capable of occupation than any other area of the earth's surface. At Fort Hope, Repulse bay, there are but two months, July and August, in which the mean temperature is above freezing; while at Yakutsk, East Siberia, in nearly the same latitude, there are five months with the mean above freezing, and the summer mean is 58.5° , compared with 39.7° at Repulse bay. —In the northeast of Ireland, says Humboldt, lying under the same parallel of latitude as Königsberg in Prussia, the myrtle blooms as luxuriantly as in Portugal. The mean temperature of the month of August, which in Hungary rises to 70° , scarcely reaches 61° at Dublin, which is situated in the isothermal line of 49° ; the mean winter temperature, which falls to about 28° at Pesth, is 40° in Dublin (whose mean annual temperature is not more than 49°), 3.6° higher than that of Milan, Pavia, Padua, and the whole of Lombardy, where the mean annual temperature is upward of 55° . At Stromness in the Orkneys, scarcely half a degree further south than Stockholm, the winter temperature is 39° , and consequently higher than that of Paris, and nearly as high as that of London. Even in the Faroe islands, at latitude 62° , the inland waters never freeze, owing to the favorable influence of the west winds and of the sea. On the charming coast of Devonshire, near Salcombe bay, which has been termed on account of the mildness of its climate the Montpellier of the north, the *agave Americana* has been seen to blossom in the open air, while orange trees trained against espaliers, and only slightly protected by matting, are found to bear fruit. There, as well as at Penzance and Gosport, and at Cherbourg on the coast of Normandy, the mean winter temperature exceeds 42° , falling short by only 2.4° of the mean winter temperature of Montpellier and Florence. In comparison with the western coast of Europe, it is believed that the western coast of America is somewhat colder, although more equable than the eastern part of the western continent.—A. Keith Johnston says: "The climates of the Asiatic coast correspond with those of America along the Atlantic; and those of Columbia, Vancouver, and Washington are duplicates of those of western Europe and the British islands. The climate of California resembles that of Spain; the sandy plains and rainless region of Lower California reminding one of Africa with its deserts between the same parallels." "The elastic atmosphere and bracing effect of the Pacific climates," says Blodget, "constitute a striking difference from those of the eastern states. All residents concur in pronouncing it more favorable to physical and mental activity than any they have known." ("Climatology of the United States," p. 200.) According to observations made at West Point, N. Y., and Fort Trumbull, Conn., both in lat. $41^{\circ} 22'$, and but $1\frac{1}{2}^{\circ}$ of longitude apart, the winters are 4.67° milder and the summers 1° cooler at

Fort Trumbull than at West Point, the former being upon the sea, and the latter inland. This difference is still more manifest in that portion of the North American continent lying north of the boundary line of the United States. In Nova Scotia, which is nearly surrounded by water, the thermometer seldom indicates a temperature higher than 88° in summer, nor more than 8° below zero in winter; but in Canada, occupying the same parallels of latitude, the thermometer in summer rises as high as 97°, and occasionally 100°, while in winter a cold of 30° below zero is frequent, and the usual range of the temperature during the winter months is from 8° to 30° below zero.—Elevation above the level of the sea exercises a decided influence on climate. The temperature of the atmosphere is found to decrease in successive and regular gradation as it leaves the sea's level, so that in the ascent of lofty mountains within the tropics the traveller experiences every change of weather, from the oppressive heat of the summer's sun on the plain below, to the piercing cold of eternal frost on the lofty summit above. The region of perpetual spring in the neighborhood of Potosi, in South America, is remembered with emotions of delight by every traveller who has ascended that ridge of the Andes. The declension of temperature has been found, with occasional variations, to equal 1° for every 300 ft. in temperate climates. This subsidence of temperature with elevation is doubtless dependent on the extreme rarity of the atmosphere at a distance from the earth, and the consequent facility with which it is permeated by heat, as well as the radiating power possessed by the earth, which enables it to return to the contiguous atmosphere a portion of the solar rays it had previously absorbed. The atmosphere is condensed in proportion to the force with which it is compressed, and expands in exact ratio to the diminution of that force. It follows that, the superincumbent strata of air being compressed with greater force in its most dependent part, and that dependent part being nearest the earth's surface, its density will be there greatest, and this density will diminish in exact proportion to the ascent of the column of air. Now the atmosphere when under a certain compression has a certain capacity for latent heat, which is increased by a diminution of the compression, and diminished by its increase. If a column of air at a certain distance from the earth receive a certain number of the sun's rays, and then be brought suddenly down to occupy a denser medium, its particles becoming compressed, a portion of the latent heat becomes sensible and is given off to surrounding bodies. The following observations, made by Mr. Green during an aerial voyage, exhibit this declension of temperature. The thermometer at the earth's surface indicated a temperature of 74°; at an elevation of 2,952 ft., 72°; at 7,288 ft., 70°; at 9,993 ft., 69°; at 11,059 ft., 45°; at 11,293

ft., 38°; making a difference of 36° between the earth's surface and the highest altitude attained, or about 1° for every 311 ft. Sir John Leslie and Humboldt believe that the diminution is much more marked near the surface of the earth than is here indicated. Mr. Glaisher, in his midday ascents, found an average fall in temperature of 1° in 223 ft. for the first 1,000 ft. with a cloudy sky, and in 162 ft. with a clear one; while above 10,000 ft. the decline was 1° in 455 and 417 ft. respectively, and above 20,000 ft. it was only 1° in nearly 1,000 ft. under both conditions. (See AERONAUTICS.) But this reduction does not apply to elevation of large areas of surface above the level of the sea. It is only applicable to actual distances from the surface, or elevations in the atmosphere itself from any general surface.—Moisture exercises very marked influence over climate. Taken as a whole, all the gentle slopes on the American continent descend eastwardly toward the Atlantic, while the abrupt ones rise on its western aspect. In this respect there is a manifest difference between this continent and that of Europe, which gradually declines westwardly toward the Atlantic. This general configuration necessarily gives to Europe a moister as well as a more temperate climate than that of America in the same parallels of latitude. This would be much more obvious were it not for the admirable compensation made by the Gulf stream and the trade wind that accompanies it. From this source not only the Atlantic coast, but the Mississippi valley, which is exposed on the south to the gulf of Mexico, derives a large proportion of its moisture. (See METEOROLOGY.)

CLIMBING PERCH. See ANABAS SCANDENS.

CLINCH, a S. E. county of Georgia, bordering on Florida, bounded S. W. by the Suwannee river, which also intersects it, and W. by the Allapaha, and intersected by the Little Suwannee; area, 1,000 sq. m.; pop. in 1870, 3,945, of whom 507 were colored. The surface is level and swampy. The Atlantic and Gulf railroad passes through the county. The chief productions in 1870 were 41,605 bushels of Indian corn, 21,054 of oats, 22,589 of sweet potatoes, 330 bales of cotton, 153,325 lbs. of rice, and 1,060 of honey. There were 263 horses, 3,201 milch cows, 6,216 other cattle, and 7,753 swine. Capital, Magnolia.

CLINCH RIVER rises among the hills of S. W. Virginia, passes into Tennessee, flows through the valley between Clinch and Powell mountains, and unites with the Holston at Kingston, to form the Tennessee. Its length is estimated at about 200 m., for more than half of which it is navigable by small boats.

CLINGMAN, Thomas L., an American politician, born at Huntsville, N. C., about 1812. He graduated at Chapel Hill university in 1832; became shortly after a member of the state legislature, and in 1843 was elected to congress, remaining a member of the house of representatives, with the exception of a single term, till 1858, and becoming chairman of the com-

mittee on foreign affairs. He was originally a whig, but subsequently joined the democratic party. In 1858 he was appointed to the United States senate, to fill the vacancy occasioned by the resignation of Mr. Biggs, and in 1860 was elected senator for a full term. Upon the approach of the civil war he opposed measures looking to the use of force against the South. In May, 1861, he was sent as a commissioner to the confederate congress, to give assurances that North Carolina would cooperate with the Confederate States, and was invited to participate in the discussions of that body. In July he was expelled from the senate of the United States, and afterward served as a colonel in the confederate army. He made valuable contributions to the knowledge of the geology and mineralogy of North Carolina, especially as to its mountains, one of the highest peaks of which has received his name.

CLINIAS. I. The father of Alcibiades. He served with the greatest distinction against the Persians in the naval battle at Artemisium, 480 B. C., with 200 men on board a trireme which he had furnished at his own expense. He was slain at the battle of Coronæa in 447 B. C., when the Athenians were defeated by the Bœotian and Eubœan exiles. His younger son, also named Clinias, was according to Plato almost a madman. II. A Pythagorean philosopher of Tarentum, a friend of Plato. In obedience to the Pythagorean principle, he was accustomed to assuage his anger by playing upon the harp. When Porus of Cyrene had lost all his fortune through a political revolution, Clinias, who knew nothing of him except that he was a Pythagorean, went to Cyrene and supplied him with money to the full extent of his loss. He, with Amyclas, dissuaded Plato from burning the works of Democritus.

CLINOMETER (Gr. *κλίειν*, to incline, and *μέτρον*, a measure), an instrument for measuring the angle made by any plane with the horizontal, and commonly used for determining the dip of beds of rock and the inclination of veins. It is made in various forms, as in that of a rule with a graduated arc upon the hinge to mark the angle of opening of the two arms. A spirit level attached to one arm serves to keep this in the horizontal plane, while the other is opened to coincide with the plane of the stratum of rock. Another convenient form is made by suspending a small metallic index upon the pivot of the needle of a pocket compass, which, by swinging freely, indicates the vertical line. The box is either square, or one side is furnished with a projecting limb, which forms a tangent to the circle at the zero point of the graduation. This tangent line being applied to a horizontal plane, the index marks zero; upon an inclined plane it marks the number of degrees this deviates from the horizontal.—In the French marine service, a clinometer is employed for determining the inclination of the keels of vessels at sea, in order to trim them for that draught of water fore and aft at which

they are known to sail best. The instrument adopted by the royal marine is that of M. Coninck, described in the *Dictionnaire du commerce et des marchandises* of M. Perpigna. It is made of two elongated glass bulbs, placed about 18 inches apart, and connected by a glass tube proceeding from their bases. Each bulb is half filled with mercury. From the upper extremity of each a tube proceeds, parallel with that at the base to within an inch of meeting, where they turn up in a vertical direction. To these vertical tubes is attached an index or vertical, which supports a scale of 2 degrees, divided into 120 minutes. Alcohol colored red is poured into the tubes until it fills them up to the point marked zero upon the scale. It rests upon the mercury, which transmits to the alcohol its oscillations. A bulb upon the summit of each of the tubes receives the alcohol when the violent movement of the ship causes it to flow over the open ends of the tubes. The angle of inclination being determined by the scale, and the length of the keel being known, the difference of draught at each extremity is easily calculated.

CLINTON, the name of nine counties in the United States. I. The N. E. county of New York, bordering on Lake Champlain, bounded N. by Canada and S. by the Ausable river; area, 952 sq. m.; pop. in 1870, 47,970. The surface near the lake is level, but becomes hilly and mountainous toward the western part of the county. Timber is abundant, and the soil is fertile. The mountains contain valuable mines of iron, the ore being abundant, and of superior quality. Dannemora is the seat of a state prison, which in 1871 had 529 inmates. The convicts are employed in digging, separating, and preparing iron ore for the neighboring furnaces. The county is traversed by the Vermont and Canada, the Montreal and Plattsburgh, and the Whitehall and Plattsburgh railroads. The chief productions in 1870 were 81,410 bushels of wheat, 106,256 of Indian corn, 520,609 of oats, 92,443 of buckwheat, 41,243 of peas and beans, 844,703 of potatoes, 66,470 tons of hay, 965,608 lbs. of butter, 151,525 of wool, and 163,036 of maple sugar. There were 7,883 horses, 10,972 milch cows, 10,740 other cattle, 40,391 sheep, and 4,466 swine; 5 manufactories of charcoal, 19 of starch, 4 of woollen goods, 15 of iron, 1 of nails and spikes, 8 grist mills, 14 tanneries, 3 planing mills, 63 saw mills, 3 manufactories of boots and shoes, 3 of carriages and wagons, 1 of cordage and twine, 5 of furniture, 6 of iron castings, 3 of machinery, 3 of perfumery and fancy soaps, 12 of saddlery and harness, 3 of sashes, doors, and blinds, and 9 leather-carrying establishments. Capital, Plattsburgh. II. A N. central county of Pennsylvania, traversed by the W. branch of the Susquehanna; pop. in 1870, 23,211. The former area was about 1,000 sq. m., but it has been somewhat diminished by taking a portion for Cameron county. The surface is mountainous, the Alleghany ridge extending

along the eastern border. It abounds in iron, coal, and timber. The county is traversed by the West Branch canal and the Philadelphia and Erie railroad, and the Bald Eagle division of the Pennsylvania Central. The chief productions in 1870 were 147,067 bushels of wheat, 458,716 of Indian corn, 209,813 of oats, 55,203 of potatoes, 11,442 tons of hay, 218,250 lbs. of butter, 17,149 of wool, and 36,169 of tobacco. There were 2,512 horses, 2,784 milch cows, 3,950 other cattle, 6,045 sheep, and 6,983 swine; 10 flour mills, 47 saw mills, 2 manufactories of sashes, doors, and blinds, 9 of carriages and wagons, 2 of edge tools, 7 of bricks, 7 of furniture, 2 of pig iron and blooms, 5 of iron castings, 2 of machinery, 1 planing mill, and 8 tanneries. Capital, Lock Haven. **III.** A S. county of Kentucky, bordering on Tennessee, bounded N. by the Cumberland river; area, about 350 sq. m.; pop. in 1870, 6,497, of whom 292 were colored. The surface is hilly, Poplar mountain in the E. part, 1,000 feet high, being the principal summit. The soil is fertile, though little improved. Coal and iron are abundant, and there is good water power. The chief productions in 1870 were 28,770 bushels of wheat, 198,602 of Indian corn, 37,881 of oats, 12,395 of Irish and 9,547 of sweet potatoes, 311 tons of hay, 70,821 lbs. of butter, 14,946 of wool, and 117,238 of tobacco. There were 1,626 horses, 1,534 milch cows, 2,547 other cattle, 6,741 sheep, and 9,800 swine. Capital, Albany. **IV.** A S. W. county of Ohio, area, 467 sq. m.; pop. in 1870, 21,914. It has an undulating surface and fertile soil. It is traversed by the Marietta and Cincinnati railroad, the Cincinnati and Muskingum Valley, and Hillsboro' branch. The chief productions in 1870 were 329,802 bushels of wheat, 158,997 of Indian corn, 109,238 of oats, 64,682 of potatoes, 23,400 of flax seed, 12,919 tons of hay, 348,150 lbs. of butter, 142,221 of wool, and 62,641 of maple sugar. There were 7,219 horses, 5,390 milch cows, 8,398 other cattle, 38,826 sheep, and 39,243 swine; 14 manufactories of carriages and wagons, 9 of saddlery and harness, 2 of woollen goods, 15 of bricks, and 15 flour mills. Capital, Wilmington. **V.** A S. central county of Michigan, drained by Grand, Maple, and Looking-glass rivers; area, 576 sq. m.; pop. in 1870, 22,845. The surface is flat, and there are extensive forests. The soil is fertile. The Detroit, Lansing, and Lake Michigan railroad intersects the S. W. corner, the Jackson, Lansing, and Saginaw railroad the S. E. corner, and the Detroit and Milwaukee railroad traverses the county. The chief productions in 1870 were 497,030 bushels of wheat, 274,606 of Indian corn, 285,419 of oats, 227,140 of potatoes, 20,369 tons of hay, 796,970 lbs. of butter, 196,444 of wool, and 39,151 of hops. There were 5,313 horses, 6,620 milch cows, 9,935 other cattle, 44,895 sheep, and 10,151 swine; 8 flour mills, 18 saw mills, 6 manufactories of agricultural implements, 9 of carriages and wagons, 6 of tin, copper, and

sheet-iron ware, 1 of woodenware, and 3 planing mills. Capital, De Witt. **VI.** A central county of Indiana; area, about 432 sq. m.; pop. in 1870, 17,330. The surface is level and the soil fertile. With the exception of a few prairies, the largest of which is 12 m. long and 4 m. wide, it is covered by dense forests. The Indianapolis, Cincinnati, and Lafayette railroad intersects the S. W. corner. The chief productions in 1870 were 535,354 bushels of wheat, 980,891 of Indian corn, 140,389 of oats, 53,270 of potatoes, 6,392 of flax seed, 10,767 tons of hay, 502,253 lbs. of butter, 87,861 of wool, and 24,300 gallons of sorghum molasses. There were 7,763 horses, 5,890 milch cows, 7,377 other cattle, 25,537 sheep, and 28,542 swine; 10 flour mills, 35 saw mills, 2 manufactories of boots and shoes, 17 of carriages and wagons, 7 of furniture, and 5 of saddlery and harness. Capital, Frankfort. **VII.** A S. W. county of Illinois; area, 420 sq. m.; pop. in 1870, 16,285. Kaskaskia river, Shoal, Beaver, and Crooked creeks are the principal streams. The surface consists mainly of fertile prairies interspersed with tracts of forest. The Ohio and Mississippi railroad passes through the county, and the Illinois Central railroad touches the S. E. corner. The chief productions in 1870 were 611,388 bushels of wheat, 813,257 of Indian corn, 446,324 of oats, 76,297 of potatoes, 11,585 tons of hay, and 169,055 lbs. of butter. There were 5,903 horses, 3,739 milch cows, 4,114 other cattle, 5,358 sheep, and 17,911 swine; 3 manufactories of furniture, 12 of carriages and wagons, and 10 grist mills. Capital, Carlyle. **VIII.** An E. county of Iowa, bordering on Illinois, bounded E. by the Mississippi, and S. by the Wapipinicon river, which intersects the S. W. corner; area, 696 sq. m.; pop. in 1870, 35,357. Prairies and forests are scattered over the surface, and the soil is generally productive. Peat is found. The Chicago and Northwestern railroad passes through it. The chief productions in 1870 were 954,175 bushels of wheat, 2,493,660 of Indian corn, 912,469 of oats, 199,072 of barley, 231,348 of potatoes, 16,170 of flax seed, 52,706 tons of hay, 989,896 lbs. of butter, and 44,269 of wool. There were 14,520 horses, 13,564 milch cows, 20,120 other cattle, 9,633 sheep, and 39,485 swine; 11 flour mills, 8 saw mills, 10 manufactories of carriages and wagons, 4 of furniture, 3 of iron castings, 3 of machinery, 1 of matches, 1 of paper, 2 of sashes, doors, and blinds, 1 distillery, and 5 breweries. Capital, De Witt. **IX.** A N. W. county of Missouri; area, 460 sq. m.; pop. in 1870, 14,063, of whom 683 were colored. The surface is chiefly prairie, in some places well wooded. Sandstone and limestone underlie the soil, which is generally fertile. The Hannibal and St. Joseph railroad skirts the N. border, and its Cameron and Kansas City branch, and the Lexington and St. Joseph branch of the western division of the North Missouri railroad pass through it. The chief productions in 1870

were 93,770 bushels of wheat, 1,147,395 of Indian corn, 239,598 of oats, 62,759 of potatoes, 7,382 tons of hay, 200,688 lbs. of butter, and 44,714 of wool. There were 6,095 horses, 1,504 mules and asses, 4,224 milch cows, 9,433 other cattle, 14,096 sheep, and 25,921 swine; 5 manufactories of carriages and wagons, 6 of saddlery and harness, 6 of tin, copper, and sheet-iron ware, 2 wool-carding and cloth-dressing establishments, 4 saw mills, and 6 flour mills. Capital, Plattsburgh.

CLINTON, a city of Clinton co., Iowa, on the Mississippi, about 42 m. above Davenport; pop. in 1870, 6,129. The river is here crossed by an iron drawbridge, 4,100 ft. long, which cost \$600,000. The Chicago and Northwestern railroad has here its repair shops, and there is a large number of saw mills, one of which is capable of producing 200,000 ft. of lumber a day. There is a national bank, and a tri-weekly and three weekly newspapers, of which one is in German. In 1871 there were 26 public schools, with 28 teachers and 1,331 pupils.

CLINTON, the name of several towns and villages in the United States. **I.** A town of Worcester co., Mass., on Nashua river, 32 m. W. of Boston; pop. in 1870, 5,429. It is a thriving manufacturing place, and contains a number of large mills and factories, supplied with water power by the Nashua river. The principal establishments are 2 cotton mills, with 24,612 spindles, manufacturing 4,353,362 yards of ginghams annually, and employing 340 males and 560 females, capital \$840,000; 1 woollen carpet mill, with 3 sets of machinery, manufacturing 364,300 yards of carpeting, and employing 161 males and 172 females, capital \$500,000; 1 manufactory of hollow ware and castings, capital \$10,000; 1 of cotton, woollen, and other machinery, capital \$20,000; 3 of combs, capital \$10,200; 1 of wire cloth, capital \$100,000; and 1 of hoop-skirt material, capital \$12,000. There are employed in the manufacture of boots and shoes 58 males and 25 females; value of product, \$121,500. The Lancaster or gingham mills are thought to be the most complete of the kind in the United States. The buildings occupy four acres of ground on the bank of the stream; this company also manufactures counterpanes; it has a dye house, said to be the best in the world. The Bigelow carpet company produces superior Brussels carpeting. There are several handsome churches, good schools, and a weekly newspaper. The Boston, Clinton, and Fitchburg, and the Worcester and Nashua railroads pass through the town. **II.** A post village of Kirkland township, Oneida co., N. Y., built on both sides of Oriskany creek, and on the Chenango canal, 7 m. S. W. of Utica; pop. in 1870, 1,640. It is the seat of Hamilton college, and contains several churches. (See HAMILTON COLLEGE.) A weekly paper and a monthly periodical are published here. The Utica, Clinton, and Binghamton railroad passes through it. **III.** A borough and township of Hunterdon co., N. J., 31 m.

N. W. of Trenton; pop. of the township in 1870, 3,134; of the borough, 785. It is situated on the south branch of Raritan river, and contains several mills and factories. The surrounding country is very productive and highly cultivated, and is noted for its limestone quarries. A weekly newspaper is published here. The New Jersey Central railroad passes through it. **IV.** A post village and the capital of E. Feliciana parish, La., 85 m. N. W. of New Orleans; pop. in 1870, 930, of whom 297 were colored. Two weekly newspapers are published. A railroad connects it with Port Hudson.

CLINTON, Charles, the ancestor of the Clintons in New York, born in the county of Longford, Ireland, in 1690, died in what is now Orange co., N. Y., Nov. 19, 1773. His grandfather was an adherent of Charles I., and after the defeat of the royalists fled for refuge to the north of Ireland; and his mother was daughter of a captain in the parliamentary army. Having determined with a number of his friends to emigrate to America, he chartered a ship, and sailed for Philadelphia, May 20, 1729. After a passage marked by the attempt of the captain to starve the passengers in order to possess their property, and in which after the death of several, among whom were a son and daughter of Mr. Clinton, it was proposed, but not attempted, to wrest the command from the captain, he was landed with his companions, Oct. 4, at Cape Cod. The place for a permanent settlement was selected in the spring of 1731 in Ulster co., N. Y., about 6 m. W. of the Hudson river, and 60 m. N. of New York city. Mr. Clinton was chiefly occupied as a farmer and land surveyor, but was also judge of the county court, and in 1756 was appointed lieutenant colonel, and served with two of his sons in the expedition against Fort Frontenac.

CLINTON, De Witt, an American statesman, grandson of the preceding, and son of James Clinton and Mary De Witt, born at Little Britain, New Windsor, Orange co., N. Y., March 2, 1769, died in Albany, Feb. 11, 1828. His descent on the father's side was from English ancestors long domiciled in Ireland, and on the mother's side he was of Dutch and French extraction. His education was begun in a grammar school near his home, continued at the academy in Kingston, and completed at Columbia college, where he bore away the college honors in 1786. He immediately engaged in the study of the law under the instruction of Samuel Jones in the city of New York, and was admitted to the bar in 1788. His ardent temper and earnest ambition carried him at once into the political field, and his sentiments, sympathies, and affections determined his position under the banner of his kinsman George Clinton, the chief within the state of the republican party. While the question of the adoption of the federal constitution was yet a subject of popular discussion, he proved his zeal and controversial power by writing a series of letters signed "A Countryman," in

reply to the "Federalist." He attended the state convention which adopted the constitution, and reported its interesting debates for the press; and forsaking his profession, he became the private secretary of George Clinton, then governor of New York. In this position he maintained the cause of his kinsman and that of the republicans by such a vigorous use of the press, that he immediately came to be regarded as its leading and most prominent champion. About this time he was appointed one of the secretaries of the newly organized board of regents of the university, and secretary of the board of commissioners of fortifications of the state. On the retirement of George Clinton in 1795, and the accession of Mr. Jay to the chair of state, De Witt Clinton relinquished his offices, but did not relax his championship of the republican cause in opposition to the administration of Mr. Jay in the state and to that of John Adams at Washington. With all his vehemence of partisan feeling, he nevertheless adhered to the line of patriotic conduct he had early marked out for himself. Thus, while assailing the administration of Mr. Adams and the federalists for their alleged hostility toward France, he raised, equipped, commanded, and disciplined an artillery company which was held in readiness for the defence of the country in the event of the occurrence of war with France, then so generally anticipated. Besides these occupations, he applied himself diligently to the studies of natural philosophy, natural history, and other sciences. In 1797 he was sent to the assembly, the lower house of the legislature of New York, by the city of New York, and in the next year was elected to the senate of the state for a term of four years. The republican party, triumphing in the Union in 1800, carried also a majority in the state of New York, although John Jay still remained in office. Official patronage in the state was committed by its first constitution to the governor, together with a council consisting of one senator from each district, chosen by a vote of the house of assembly. The governor presided in the council, and habitually exercised exclusively the right of nomination, leaving only to the council the power to confirm or reject. During the administration of George Clinton his opponents, when in a majority in the council, had claimed for each member a right of nomination coördinate with that of the governor; but the pretension was disallowed by Gov. Clinton, and the original practice remained. De Witt Clinton in 1801 became a member of the council, backed by a republican majority. He now challenged the right of nomination for himself and his associates. The governor denied it, and adjourned the council, and never afterward reconvened it. He submitted the subject to the legislature, and appealed to that body for a declaratory law. Clinton vigorously defended the position assumed by him in the council. The legislature referred the matter to a convention of the people. The republican party predomi-

nated in that body, and the constitution was amended so as to effect the object at which Clinton had aimed. It was a season of apprehended invasion; Clinton was active and efficient in securing the means of public defence. The public health was continually threatened by the approach of contagious pestilence; he was unremitting and judicious in providing the necessary sanitary laws and institutions. He urged improvement of the laws in favor of agriculture, manufactures, and the arts, labored to stimulate the great and finally successful effort of the time to bring steam into use as an agent of navigation, and employed all his talents and influence in meliorating the evils of imprisonment for debt, and in abolishing slavery. At the early age of 33 his term of brilliant service in the senate of the state was crowned by his appointment to a seat in the senate of the United States. He remained in that body through two of its annual sessions. The period, though short, sufficed to enable him to impress upon the country a conviction of his great ability, and to enlarge the sphere of his already eminent reputation. His principal achievement there was an elaborate, exhaustive, and impressive speech in favor of moderation on the occasion of a high popular excitement against Spain, resulting from her violation of treaty stipulations for commercial privileges to the citizens of the United States on the banks of the Mississippi, the territory of Louisiana not yet having been acquired by the United States. Clinton resigned his place in the senate to assume the office of mayor of the city of New York, under an appointment made by George Clinton (again governor) and a republican council of appointment in 1803. He remained undisturbed in the mayoralty from 1803 to 1807, when he was removed. He was reappointed in 1809, displaced in 1810, restored in 1811, and thenceforward continued therein till 1815. Within this period of nearly 12 years he was also a member of the senate of the state from 1805 to 1811, and lieutenant governor from 1811 to 1813; and during a portion of the time he also held a seat in the council of appointment. In 1804 George Clinton, who had been known as an aspirant to the presidency for many years, was elected vice president of the United States, and soon after, by reason of his advanced years, ceased to be conspicuous. De Witt Clinton, by an easy transition, rose to the same eminent consideration, and came to be regarded as the foremost candidate of the republican party within the state of New York for the presidency. Not at all abating either his personal activity or his proscriptive severity toward others, he encountered at their hands hostility and retaliation, fierce, violent, and apparently relentless. A dangerous rival disappeared when Aaron Burr sank under the odium of intrigues against Jefferson in the election of 1800, and the still greater odium of the fatal duel with Hamilton in 1804; but Clinton was

successively brought into an attitude of distrust toward Lewis and Tompkins, the successors of George Clinton in the office of governor. He hesitated to approve the system of commercial restrictions adopted by President Jefferson, and questioned the wisdom of the course of Madison immediately previous to the declaration of war against Great Britain. It is beyond all doubt now that Clinton was eminently brave, and that he loved his country with a devotion that knew no hesitation when her safety or welfare required sacrifice at his hands. But there was at that time a portion of the federal party which condemned the measures of the government so severely that their own loyalty to the country was not unnaturally questioned, and their conduct, whatever were their motives, had a tendency to encourage the public enemy, and so to embarrass the administration. This brought suspicion on the whole federal party, although as a mass it was loyal and patriotic, and it suited the purposes of Clinton's opponents to impute his hesitation and reserve to the influence of sympathies with the federalists. Day by day, therefore, old republican associates and followers separated from him, and in their places federalists, who saw that there was no longer any hope of effectually serving their country under their own dilapidated organization, and who believed him as patriotic as the statesmen who were in power, and much wiser than they, lent him indirectly their sympathy and cautious support. It was in this unlucky conjuncture that Clinton, whose aspirations to the presidency had long been known, concluded that the time had arrived when they ought to be and could be realized. Madison's first term was to expire in 1813, and his successor was to be elected in 1812. The republican caucus at Washington disallowed Clinton's pretensions, and renominated Madison. Clinton still retained the confidence of the republican party in his own state as an organized political force, though it was sadly demoralized. He received a nomination at the hands of the republican members of the legislature. The federalists made no nomination, and indirectly gave him their support. He received 89 electoral votes, while Madison received 128, and thus was re-elected. This defeat was disastrous to Clinton. The republican party of the state of New York shrank from his side, and at the first opportunity in 1813 displaced him from his office of lieutenant governor, leaving him only the mayoralty of the city of New York. But in fact he had changed not his principles, policies, or sympathies, but only his personal relations. He had attempted to gain the presidency, not to overthrow the republican party, but to re-establish it, as he thought, on a better foundation; not to favor the public enemy, but to prosecute the war against him, as he thought, with greater vigor and effect. The result was a complexity of relations that seemed to render all further ambition hopeless. He was a re-

publican disowned by his party; and though not a federalist, was held responsible for the offences imputed to that party, without having their confidence, or even enjoying their sympathy. His fall seemed irretrievable. Nevertheless, he had been fortunate during the period which we have been reviewing in laying broad and deep the foundations of a popularity that at no distant day might be made to maintain a personal party, which would long perplex and often confound the adversaries who now exulted over what was thought his final ruin. The city of New York had now begun to feel the beneficial influence of the centralization of commerce under the operation of the federal constitution, and public spirit was profoundly awakened. The deficiencies of its municipal laws, of its defences, of its scientific and literary institutions, of its institutions of art, and the absence of most of the elements of a metropolitan character, were generally felt and confessed. Enlightened, liberal, and active men were moving in a hundred ways to make the city worthy of its high but newly discovered destiny. Only some lofty, genial, and comprehensive mind was wanted to give steadiness and direction to these movements. De Witt Clinton supplied this want. He associated himself with citizens who engaged in the establishment of schools designed to afford the advantages of universal primary education; with others who founded institutions for the study of history, for improvement in art, for melioration of criminal laws, for the encouragement of agriculture, for the establishment of manufactures, for the relief of all forms of suffering, for the correction of vice, for the improvement of morals, and for the advancement of religion. In all these associations he subjugated his ambition, and seemed not a leader but a follower of those who by their exclusive devotion were entitled to precedence. They derived from him, however, not only liberal contributions by his pen, by his speech, and from his purse, but also the aid of his already wide and potent influence, and the sanctions of his official station and character. He carried the same liberal and humane spirit into his administration as chief magistrate of the city. By virtue of that office, he was not only the head of the police, charged with the responsibilities of preserving order and guarding the city from external dangers, but he was at once a member and president of the municipal council, of the board of health, of the court of common pleas, and of the criminal court. He appeared in all these various characters always firm, dignified, intelligent, and prepared for every exigency; the friend of the poor, the defender of the exile, the guardian of the public health, the scourge of disorder, the avenger of crime, the advocate of civil and religious liberty, and the patron of knowledge and virtue. As a member of the senate of the state and lieutenant governor, he exercised the functions not only of a legislator, but also of a judge of the court of last resort;

and amid all the intrigues and distractions of party he bore himself in those high places with the dignity, and exercised the spirit, of a sagacious, far-seeing, and benevolent statesman. Especially he arrested the popular prejudice against himself in regard to his loyalty, by the utmost liberality and efficiency both as mayor and legislator in securing adequate means for public defence, by providing loans to the government, by voting supplies of materials and men, and by soliciting the military command to which his admitted courage, talent, and influence seemed to entitle him. But beyond all this, he adopted early and supported ably and efficiently the policy of the construction of canals from Lake Erie and Lake Champlain to the tide water of the Hudson, and showed to his fellow citizens, with what seemed a spirit of prophecy, the benefits which would result from those works to the city, the state, and the whole country, in regard to defence, to commerce, to increase of wealth and population, and to the stability of the Union. He was so successful in this that he was deputed, with others, in the year 1812, by the legislature of the state, to submit that great project to the federal government at Washington, and solicit its adoption or patronage of the policy as a national measure. That government, happily for the state, and fortunately for him, declined, and the occurrence of the war of 1812 put the subject to rest, to be revived at a more propitious season. The intellectual vigor, the impartial spirit, and the energetic resolution which Clinton displayed in these various duties, awakened profound and general admiration; while the manifest beneficence of his system excited enthusiastic desires for material and moral progress. He had thus become identified even in the darkest hour of his political day with the hopes and ambition of his native state, and with the hopes and ambitions of all the other states which waited to be benefited directly by her movement, or to emulate her example. By a system chosen and perfected by himself, and exclusively his own, he had gained a moral position similar and equal to that which Hamilton had won before him when, the tide of popular favor having deserted him, and left him destitute of power and influence, he still stood forth an isolated figure, attracting an admiration and exciting an interest which his successful rivals feared to contemplate. But it was not for Clinton to reascend the political ladder until he had released his hold on the lowest step, and had once more touched the ground. His opponents made haste to dislodge him from that last foothold. In January, 1815, he was removed from the mayoralty by a council of appointment in the interest of the republican party. Fortune had gone with greatness, and he sunk into private life without even the means of respectable subsistence. The severity of this proscription, coupled with the greatness of his fall, as well as of his character, awakened regrets and sympathies among large

classes who did not stop to consider how rashly he had tempted fortune, or how ruthlessly he had wielded the axe against those who had now precipitated him to the ground. In the autumn of that year, and in the obscurity of a retreat to the country, he prepared an argument in favor of the immediate construction of the Erie and Champlain canals. Never has there appeared, in this or perhaps in any other country, a state paper at once so vigorous, so genial, so comprehensive, and so conclusive. It was couched in the form of a memorial from the citizens of New York to the legislature of the state, and was deferentially submitted to a public meeting for their adoption. The city adopted the memorial, and appealed to the citizens of the interior portions of the state. They responded with enthusiasm; other states and territories lent their approving voices. The policy was from that moment certain of success. It was hindered only by the political prejudices which hung around its advocate. His opponents called these prejudices into new activity. With short-sighted malice, they affected to consider the attractive scheme as not merely a new resort of a ruined politician, but as one original with and devised by himself, impracticable, absurd, and visionary, although for more than a hundred years sagacious and enlightened statesmen connected with the affairs of the colony and of the state of New York had, with various degrees of distinctness, indicated and commended the obnoxious policy, and the state itself had at an early day made demonstrations toward its adoption, and had recommended the whole enterprise before the war to the adoption of the federal government. Clinton, if left to designate for his adversaries their mode of opposition, could have preferred no other. It presented him as not merely the advocate, but even the inventor of the system whose prospective benefits were already triumphantly demonstrated. He appeared at Albany, at the assembling of the legislature, to commend it. The governor, the organ of the republican party, was silent on the subject. The republican legislature rendered it just enough of favor to encourage and strengthen Clinton, and too little to make it their own and separate him as a necessary agent from it. It appointed him with others a commissioner to make the necessary surveys and estimates, solicit grants and donations, and report at the next session. A vacancy in the office of governor was now to occur by the transfer of the esteemed and popular Tompkins, the chief republican character in the state, to the post of vice president of the United States at Washington. Spontaneous demonstrations presented Clinton before the public as a candidate; the party machinery refused to work in the hands of his adversaries, and he was elected in the summer of 1816 to the office of governor, practically by the unanimous voice of the people. It seemed for a short time as if all partisan or-

ganization had been permanently broken up, and as if party spirit had been extinguished for ever. Notwithstanding all these pleasing auguries, the period of his administration was filled up, like former ones, with violent and embittered political controversies. He triumphed in 1819, being reëlected, though by a very small majority, over Daniel D. Tompkins, who, while yet vice president, became the opposing candidate, and brought into the canvass a popularity never before overbalanced. His adversaries availed themselves of just complaints against the constitution to move the call of a convention for its amendment, and the measure was eminently popular. Clinton hesitated so long as to become identified with the opposition to it. The convention made reforms which diminished the power of the executive and judiciary, and conceded an enlargement of the right of suffrage, with other popular rights, while it adopted his canal policy. Clinton wisely declined to be a candidate under such circumstances for a reëlection as governor, and Joseph C. Yates was called to the office with a unanimity equal to that which had attended Clinton's elevation to the same place. Faction, however, disorganized the triumphant party in 1824. At the same time the legislature in its interest abused its triumph over Clinton by removing him without notice and without cause from the now obscure office of canal commissioner, in which he was serving, as he had served from the first, only as an adviser and without any compensation. Indignation awakened by this injustice, and combined with popular discontents resulting from other causes, bore him at the end of the same year back into the office of governor by a very decided vote; but the new combination which had secured this result was committed to the support of John Quincy Adams in the federal government, while Clinton's sympathies or his views of duty or of interest determined his inclination toward, first, William H. Crawford, and then Andrew Jackson, as candidates for the presidency. He was thus once more in his old position, sustained by a party from whom he withheld his confidence and sympathy, and opposed by the one to which he looked for ultimate support. He was barely reëlected in 1826, while the legislature was opposed to him. His administration of the state government, however, which continued throughout a period of 12 years, with the exception of an intervening period of two years, was one of unequalled dignity and energy. He had the good fortune to mature the system of finance which enabled the state, unconscious of expense or care, to begin and carry out his policy of internal improvement, and to break with his own hand the ground in the beginning of the enterprise, on July 4, 1817; and overcoming constant, unremitting, and factious resistance, he had the felicity of being borne, in October, 1825, in a barge on the artificial river which he seemed to all to have constructed, connecting

Lake Erie with the bay of New York, while bells were rung and cannons saluted him at every stage of that imposing progress. No sooner had that great work been undertaken in 1817, than the population of the state began to swell with augmentation from other states and from abroad; prosperity became universal; old towns and cities expanded, new ones rose and multiplied; agriculture, manufactures, and commerce were quickened in their movements, and wealth flowed in upon the state from all directions. He inaugurated the construction of branches of the Erie canal, by which it was ultimately connected with the internal lakes, with Lake Ontario, and with the Susquehanna, the Alleghany, and the St. Lawrence rivers; and by his counsel and advice, now sought in all directions, he hastened the opening of those canals in New Jersey, Pennsylvania, Ohio, Indiana, and Illinois, which, in connection with those of New York and with natural channels, now constitute a system adequate to the internal commerce of an empire. De Witt Clinton, witnessing the enjoyment of the continually enlarging realization by the public of the benefits of his labors, died at Albany, the seat of his authority and the chief theatre of his active life. It scarcely needs to be added that party spirit was hushed into profound silence; that a grateful people mourned his death with all the pomp of national sorrow; and that posterity cherishes his memory with the homage deserved by a benefactor of mankind. While yet young Mr. Clinton married Maria Franklin, who brought him a liberal fortune, and who died in 1818. In the succeeding year he was married to Catharine Jones, who survived him. He had a commanding stature, highly intellectual features, and a graceful form, set off with severe and dignified manners. He combined in a rare degree vigor, versatility, and comprehensiveness of mind, with untiring perseverance in the exercise of a lofty and unconcealed ambition.—He published "Discourse before the New York Historical Society" (1812), "Memoir on the Antiquities of Western New York" (1818), "Letters on the Natural History and Internal Resources of New York" (1822), "Speeches to the Legislature" (1823), and several literary and historical addresses. See Hosack, "Memoir of De Witt Clinton," (1829); Renwick, "Life of De Witt Clinton" (1840); Campbell, "Life and Writings of De Witt Clinton" (1849); and "National Portrait Gallery of Distinguished Americans," vol. ii.

CLINTON, George, an American soldier and statesman, youngest son of Charles Clinton, born in Ulster co., N. Y., July 26, 1739, died at Washington, April 20, 1812. He received a careful education, directed chiefly by his father and by a Scottish clergyman who was a graduate of the university of Aberdeen, and he early signalized his enterprising character by sailing in a privateer in the French war.

He soon after joined a militia company as lieutenant, and took part in the expedition against Fort Frontenac, now Kingston, Canada. Choosing the legal profession, he practised with distinction in his native county, till in 1768 he was elected to the colonial assembly, where he soon became the head of a whig minority. He was elected to the continental congress in 1775, voted for the declaration of independence, was appointed brigadier general of the United States in 1777, and in the same year, at the first election under the constitution of New York, was chosen both governor and lieutenant governor of the state. He accepted the governorship, and by six successive elections held that office for 18 years. Both in his civil and military capacity, he exhibited great energy and rendered important services throughout the war; and though his efforts to save Forts Montgomery and Clinton in the Hudson highlands in 1777 were unsuccessful, it was yet due in a large measure to his counsels that communication was prevented between the British in Canada and the city of New York. The politics of New York were in a distracted state by reason of the numerous Tories residing within its limits, which made the chief magistracy unsurpassed in difficulty by any office in the country except that of commander-in-chief of the army.* In 1788 he presided over the convention at Poughkeepsie to consider the federal constitution, the adoption of which he opposed, not deeming it sufficiently decided in favor of the sovereignty of each state. When in 1792 Washington was elected to the presidency for the second time, Clinton received 50 electoral votes for vice president. After an interval in his official life, he was again elected in 1801 governor of New York, and in 1804 was elected vice president of the United States, receiving the same number of votes as Jefferson received for the presidency. He was one of the prominent candidates for nomination to the presidency in 1808, and received 6 electoral votes in opposition to Madison, but he was continued in the chair of vice president by 113 electoral votes. He was acting in discharge of the duties of his office at the time of his death. By his casting vote in the senate, Jan. 24, 1811, the recharter of the national bank was refused; he thinking it inexpedient rather than unconstitutional.

CLINTON, Sir Henry, an English soldier, born about 1738, died at Gibraltar in December, 1795. He was the grandson of Francis Fiennes Clinton, sixth earl of Lincoln, became a captain in the guards in 1758, served in the seven years' war, and was sent to America as major general in 1775. He took a prominent part in the battle of Bunker hill, and in the battle on Long Island which resulted in the evacuation of New York by the Americans; stormed Fort Clinton on the Hudson in 1777, in a vain effort to relieve Burgoyne; and was appointed commander-in-chief of the British land forces in America in January, 1778, superseding Gen.

Howe. After being forced by Washington to evacuate Philadelphia, he sent an expedition against Savannah in 1779, and led an army against South Carolina, capturing Charleston. In May, 1780, he entered into negotiations with Arnold; and he sailed from New York with 7,000 men to relieve Cornwallis on the very day that the latter capitulated. He was superseded by Sir Guy Carleton in 1781, returned to England in 1782, and died soon after he had been appointed governor of Gibraltar. He wrote a narrative of his conduct in America, a rejoinder to Lord Cornwallis's observations on it (1783), and "Observations on Stedman's 'History of the American War'" (1794).

CLINTON, Henry Fynes, an English author, born at Gamston, Nottinghamshire, Jan. 14, 1781, died at Welwyn, Hertfordshire, Oct. 24, 1852. He was a descendant of Henry, second earl of Lincoln, and his father, Charles, a clergyman, assumed in 1821 the surname of Fynes-Clinton. He was a graduate of Oxford, and a member of parliament for Aldborough from 1806 to 1826. He was one of the most diligent students of Greek and Latin literature; and his two principal works, the *Fasti Hellenici* (3 vols., Oxford, 1824-'34) and *Fasti Romani* (2 vols., 1845-'50), are thorough and scholar-like treatises on the civil and literary chronology of Greece and Rome.—See "Literary Remains of H. F. Clinton," by C. J. F. Clinton (1854).

CLINTON, James, an American soldier, the fourth son of Charles and father of De Witt Clinton, born in Ulster co., N. Y., Aug. 9, 1736, died at Little Britain, Orange co., Dec. 22, 1812. After receiving an excellent education, he joined the army, served in the French war as a captain under Col. Bradstreet, and distinguished himself in 1756 in the capture of Fort Frontenac, and of a sloop of war on Lake Ontario. In 1763 he commanded four regiments for the protection of the western frontiers of Ulster and Orange against the incursions of the Indians. He was appointed colonel at the outbreak of the revolutionary war, and toward the close of 1775 accompanied Montgomery to Canada. Promoted to the rank of brigadier general, he was with his brother, Gov. George Clinton, in command at Fort Clinton, on the west bank of the Hudson, when in 1777 that fort was stormed by the English; and after a gallant resistance, he escaped severely wounded with a part of the garrison across the river. In 1779 he cooperated with Gen. Sullivan in his expedition against the Iroquois. Crossing the Mohawk to Lake Otsego, one of the sources of the Susquehanna, down which he was to join Sullivan, he dammed the lake, and then by breaking the dam away produced an artificial current which carried his boats rapidly to the point of junction. An army of Indians and Tories was soon after encountered and defeated at Newtown, now Elmira. He afterward commanded at Albany, and was present at the siege of Yorktown and surren-

der of Cornwallis, and at the evacuation of New York by the British. After the close of the war he became commissioner to adjust the boundary between New York and Pennsylvania, delegate to the convention for adopting the federal constitution, and to that of 1801 for amending it, and member of the assembly and senate of New York.

CLIO, in Greek mythology, the daughter of Zeus and Mnemosyne, and the muse of glory and history. She is usually represented sit-

Clio, from an Antique Representation.

ting, with an open roll of papyrus in her left hand. Sometimes she holds a lute in one hand and a plectrum in the other.

CLISSA, or **Khissa**, a fortified town of Dalmatia, Austria, 5 m. N. E. of Spalatro; pop. about 1,500. The importance of its position, on a height commanding the route from Spalatro to the interior of the country, has always rendered it one of the first points attacked by invading armies. The Roman castle of Andretium is supposed to have been situated on Mount Clissa, in the vicinity.

CLISTHENES, an Athenian statesman, the grandson of a tyrant of Sicyon, of the same name, and the son of Megacles, and at the end of the rule of the Pisistratidæ the head of the Alcæmonidæ, their chief enemies. When, with the assistance of the Delphic oracle and the Spartans, Hippias was banished from Athens (510 B. C.), Clisthenes, in order to secure his ascendancy over his rival Isagoras, chose the defence of the cause of the people, and succeeded, with the favor of the Pythia, in introducing some important changes in the ancient constitution of Athens; among others, the division of Attica into ten instead of four tribes, each consisting of several demi, under demarchs; the increase of the number of senators from 400 to 500, 50 from each tribe; and, as some say, the law of ostracism, so remarkable in the history of that state. Clisthenes, being suspected of the desire of tyrannical power, was himself banished, but afterward returned, overcoming his enemies. He was grandfather to Pericles.

CLITHEROE, a parliamentary and municipal borough and market town of Lancashire, England, on the E. bank of the Ribble, at the base of Pendle hill, 1,800 ft. high, on the Lancashire and Yorkshire railroad, 216 m. by rail N. W. of London; pop. in 1871, 10,980. It contains an ancient parish church, a mechanics' institute, library, and reading room. There are extensive print works, cotton manufactories, paper mills, iron and brass founderies, and lime kilns, and the remains of a castle of the 12th century.

CLITOMACHUS, or, in the language of his native country, **HASDRUBAL**, a Carthaginian who went to Athens in the 40th year of his age, and, after studying under Carneades, became the head of the new academy on the death of his master in 129 B. C. Of his voluminous works only a few titles are preserved.

CLITUMNUS (now **OLITUMNO**), a little river of Italy, rising near Spoleto, and emptying into the Tinia (now Timia), a tributary of the Tiber. It was famous in ancient times for its sacred character, the beauty of its banks and environs, the excellence of its pastures, and a peculiar breed of snow-white cattle which were in great demand for sacrificial purposes, especially on days of triumph, when, with gilded horns and wreaths of flowers about their necks, the sacred steers of the Clitumnus formed no inconsiderable part of the pomp. Pliny has left a description of the river, its pastures, herds, and groves, and its little temple sacred to Jupiter Clitumnus, the remains of which are yet to be seen on the road between Spoleto and Foligno.

CLITUS, surnamed **MELAS** (the Black), a Macedonian general, foster-brother and a familiar friend of Alexander the Great, whose life he saved at the battle of the Granicus, 334 B. C. He was afterward appointed commander of a division of the royal guards, and in 328 satrap of Bactria. On the evening before he was to set out for his government he was slain by Alexander at a banquet at Maracanda in Sogdiana, when both parties were excited by wine, and Clitus had provoked the conqueror's resentment by speaking of the glory of Philip as greater than that of Alexander. The king repented bitterly of his rash deed, and caused a splendid funeral service to be held in honor of his victim.

CLIVE, **Robert**, lord, baron of Plassey, a British soldier and statesman, born at Styche, Shropshire, Sept. 29, 1725, died by his own hand in London, Nov. 22, 1774. He early displayed a bold and unmanageable temper. A clerkship having been gained for him in the service of the East India company, at the age of 18 he sailed for Madras, the voyage occupying more than a year. The only gentleman to whom he had a letter of introduction had left India before Clive's arrival, and he soon found himself in miserable circumstances. He was several times near being dismissed for insubordination, and twice he attempted suicide. On the second occasion, when the pistol missed

fire, he exclaimed that he must be reserved for something great. Madras having fallen into the hands of the French, Clive at night fled from the city, disguised as a Mohammedan, and arrived safely at Fort St. David. He now, at the age of 21, obtained an ensign's commission in the military service of the company, and distinguished himself in several operations against the French. Although peace was soon concluded between England and France in Europe, the French and English trading companies in India continued to be upon hostile terms. Dupleix, the French commander, had gained absolute power over the Deccan, the nominal native ruler being only a puppet set up by himself. The English were alarmed for their establishments, even for their existence in India. They recognized Mohammed Ali as nabob of the Carnatic, against Chunda Sahib, supported by the French; but his dominions now consisted alone of Trichinopoly, and even this place was besieged by Chunda Sahib and the French auxiliaries. Arcot, the capital of the Carnatic, was decided upon as a point of attack; and in the absence of Major Lawrence, who had gone to England, all eyes were turned to Clive. He was now 25 years of age, and had acquired a name for desperate courage, sagacity, and military genius. He assured his superiors that unless some decisive move was at once made on Arcot, Trichinopoly would fall, and the French, becoming entire masters of India, would expel the English. His advice prevailed, and he was placed at the head of 200 British troops and 300 sepoy. He marched on Arcot and took it without a blow, the garrison being panic-struck; but knowing that he would not be long suffered to remain unmolested, he made vigorous preparations for defence (August, 1751). As soon as the news reached Chunda Sahib, he invested Arcot with about 10,000 men commanded by his son, Rajah Sahib. For more than 50 days Clive sustained the siege against this overwhelming force; his little band in the mean time, although suffering with hunger, manifesting great devotion to their young commander. An attempt by the government of Madras to relieve him had failed, but a body of 6,000 Mahrattas were on the march to succor the English. Before they could arrive, Chunda Sahib determined to storm the fort. He chose for the day of the assault the anniversary of the death of Hosein, the son of Ali, when devout Mussulmans are stirred to the wildest fanaticism, and have an implicit faith that whoever then falls in battle against the infidel passes at once to the eternal joys of paradise. Clive had received secret notice of the proposed attack, and had made arrangements to meet it. The enemy came on driving elephants before them, whose foreheads were armed with iron plates to batter down the gates. As soon as they felt the musket balls, they turned furiously around, and threw their drivers into confusion. Clive everywhere animated his troops, exposing him-

self to the greatest dangers; and after three desperate assaults and an hour's conflict, the assailants retired behind the ditch, and under cover of night retreated, leaving several guns and a quantity of ammunition. They lost 400 men, while the besieged lost but 5 or 6. This exploit was received at Madras with exultation; 200 English soldiers and 700 sepoy were sent to Clive, who at once began offensive operations. He took the fort of Timery, joined a party of Mahrattas, attacked Rajah Sahib, who had 5,000 men, of whom 300 were French, defeated him, seized his military chest, routed him in a second battle, marched to Fort St. David, and on his way razed to the ground the monument which Dupleix had erected to his own glory, as well as the city which had since sprung up in the vicinity. Clive now triumphed everywhere, although in some cases his troops were of the worst order. The important forts of Covelong and Chingleput, garrisoned by French soldiers, fell into his hands; and after these successes he returned to Madras and married Miss Maskelyne, sister of the celebrated astronomer royal. His health was much broken, and he shortly afterward sailed for England. On his arrival there in 1753, he was received with the highest distinction. The East India company presented him with a rich diamond-hilted sword, which he refused to accept until one of equal value was voted to his superior officer, Major Lawrence, whose merits he declared not inferior to his own. He remained about two years in England, spending his money profusely, aiding his poor relations, and contesting a seat in parliament, to which he was elected, but was at once deprived of it by the vote of a small majority in the house. In 1755 he embarked for India with the rank of lieutenant colonel. He was now employed, in connection with Admirals Watson and Pocock, in reducing the stronghold of Gheriah, the haunt of a pirate named Angria, the terror of the Arabian sea. The place was captured, and booty to the amount of £150,000 divided among the conquerors. He then proceeded to his government of Fort St. David, and had been there but about two months when Surajah Dowlah, the nabob of Bengal, seized Fort William, the citadel of Calcutta (June 20, 1756), and flung his English prisoners, 146 in number, into the garrison prison, known as the "black hole," a dungeon only 18 ft. square, and all except 23 of them perished. (See BLACK HOLE.) To inflict vengeance for the massacre, an expedition was placed under the joint command of Clive and Admiral Watson; and 900 English infantry and 1,500 sepoy sailed from Madras in October, but owing to head winds did not reach Bengal until December. The nabob was at Moorshedabad when he heard of the arrival of the English on the Hoogly, and instantly assembled his army and marched toward Calcutta. Clive took Budgebudge, Fort William, and Calcutta, and stormed and sacked Hoogly

(January, 1757), when the nabob thought it best to come to terms, which Clive was unwilling to allow, but was overruled by a committee of the company's servants. The negotiations between Surajah Dowlah and the English were conducted chiefly through two agents, Mr. Watts, an Englishman, and Omichund, a treacherous Bengalee. From the nabob's cruelties and insignificance, a plot was formed against him, and Clive lent all his influence to the conspirators in aid of their plan of deposing him and placing Meer Jaffier, the principal commander of the nabob's troops, on the throne of Bengal. In return for this aid Meer Jaffier was to make the most ample rewards to the English. Omichund, who had the entire confidence of Surajah Dowlah, by systematic deceit lulled all his suspicions. Clive knew Omichund to be a villain, and was resolved to outdo him in deceit if necessary. Meanwhile he was writing the nabob the most friendly letters, and at the same time plotting with his general, Meer Jaffier, who was to desert his master at a critical moment with large bodies of troops. Just as the plot was ripe, Omichund played false to the English, and demanded as the price of good faith £300,000, or he would divulge the whole scheme to Surajah Dowlah. Clive, in order to punish Omichund for his treachery, resolved himself to act the part of a traitor. He promised what was asked. The wily Bengalee insisted that his claims should be mentioned in the treaty between Meer Jaffier and the English. Clive had two treaties drawn up, the real one on white paper, and a spurious one on red. The white contained no mention of him. To the red one, which Omichund insisted should bear Admiral Watson's signature, that officer refused to affix his name, and Clive was actually accused of having forged it, although he afterward denied the charge. All was now ready. Watts fled secretly from Moorshedabad, and Clive put his troops in motion. The battle which followed proved of immense importance for the power of Britain in India. Clive's army consisted of 3,000 men, only 900 of whom were Europeans. He met the Indian forces within a mile of Plassey, June 23. The latter consisted of 40,000 infantry, armed with firelocks, pikes, bows and arrows, and swords, with 50 pieces of huge cannon drawn into the field by elephants and oxen, supported by 15,000 cavalry from the northern provinces, far superior to those of the Carnatic. The nabob's ordnance opened fire with little execution, while the well trained English artillery was served with deadly effect. The nabob ordered a retreat, upon which Clive advanced, and the enemy fled in utter rout; only 500 were killed, but they lost all their ordnance and equipage. The English loss was 22 killed and 50 wounded. Meer Jaffier had given no aid during the action, but, drawing off his forces when it was decided, was shortly installed by Clive as nabob of Bengal Bahar, and Orissa; while Surajah Dowlah

fled, but was captured a few days afterward, and executed by the orders of his late general. Meer Jaffier was now called upon to reward his allies, and Omichund came among the rest; but on being told how he had been overreached by Clive, he sank into idiocy, and died a few months afterward. Immense wealth now fell upon the company, and Clive was conducted by Meer Jaffier into the great treasury of Bengal at Moorshedabad, with full leave to help himself, and he took about £250,000. Later in life, when his conduct was impeached in the house of commons, he vigorously defended himself before the committee, and, alluding to the wealth showered upon him, described the glittering heaps on which he had gazed, and exclaimed, "By God, Mr. Chairman, at this moment I stand astonished at my own moderation." Clive's great victory over Surajah Dowlah was soon followed by the defeat of the army of the Great Mogul, sent against Meer Jaffier, which he overcame at Patna; and in 1759 by his victory over the troops sent by the governor of Batavia under pretence of assisting the Dutch colonies, but really to disturb the British in their possessions. New honors and wealth were showered upon him, and Meer Jaffier granted him an annual revenue of £28,000. In 1760 he returned to England, where he was raised to the Irish peerage with the title of Baron Clive of Plassey, and was elected to parliament as one of the members for Shrewsbury. He remained in England about four years, applying himself chiefly to Indian affairs, while his immense fortune enabled him to live in magnificence. During his absence from Bengal the affairs of the company fell into utter confusion; it was not enriched, while crowds of adventurers returned from India with splendid fortunes, acquired in a short time from systematic oppression and plunder of the hapless natives. At length these evils reached such a pitch that the speedy ruin of the Anglo-Indian empire was prophesied unless some strong hand should interpose, and Clive was looked to as the only man who could save it from destruction. After much solicitation he consented to go back to India, and was appointed governor and commander-in-chief of the British possessions in Bengal; and in May, 1765, for the third time he reached Hindostan. At Calcutta he found everything fearfully disorganized, far more than he had anticipated. But he proceeded at once to the reformation of all abuses in spite of great opposition. On one occasion 200 officers of the army, who had been engaged in commercial speculations, combined and resigned their commissions, thinking to terrify him into submission by the spectacle of an army without leaders. Clive instantly issued commissions for new officers, even to mercantile agents who were disposed to aid him; the sepoys he had himself trained in battle stood firm in their devotion to him, and he ordered that every officer who resigned should at once be brought to Calcutta. The insubordination was quelled,

the ringleaders were punished, and the others pardoned. He returned from India, July 14, 1767. In 1772 his proceedings in India were made the subject of public discussion, and in 1773 a select committee of investigation was appointed by the house of commons. Clive successfully vindicated his conduct. The charge of fraud brought against him was rescinded by a vote of the house, and a motion agreed to by a large majority, "that Lord Clive had rendered great and meritorious services to his country." But for some time his health had been giving way, and to relieve his sufferings he resorted to opium, which gradually ruined his strong intellect. He had labored all his life under periodic fits of melancholy, and in one of these he committed suicide.—See Malcolm, "The Life of Robert Lord Clive" (3 vols. 8vo, London, 1836), and Macaulay's review of it (1840); and Gleig, "Life of Lord Clive" (1848).

CLOACÆ (Lat. *cloaca*, a conduit, pipe), the sewers of ancient Rome. The trunk drain, called the *cloaca maxima*, is formed by three tiers of concentric arches overlying each other in contact; the whole work is 15 ft. wide by 30 ft. in height. The masonry is of hewn stone, laid without cement. Along this subterranean street the drainage of the city, as well as the surplus waters of the aqueduct, discharged themselves into the river. The cleansing and repairing of the cloacæ were confided at first to the censors, afterward to the *ædiles*, and subsequently to commissioners entitled curators of the cloacæ, who employed convicts in the work, and levied the expense by assessment. Tarquin the Elder is said to have originated these works about 150 years after the foundation of the city, for the purpose of draining the marshy ground between the Palatine and Capitoline hills. Agrippa sailed through the *cloaca maxima* in a boat. Nero caused his victims to be thrown into the sewers. The cloacæ yet serve in part for the drainage of Rome, and several modern cities are drained similarly.

CLOACINA, one of the Roman surnames of Venus. Pliny derives the appellation from the obsolete verb *cloare* or *cluere*, to wash, and adds that when the Sabine women prevented their relatives from taking vengeance on their ravishers, both armies purified themselves by rites before the statue of Venus, who was hence called goddess of purification. Livy attributes the appellation to the circumstance that the Sabine king Titus Tatius found a statue of Venus in the *cloaca maxima*, which he set up, and consecrated under the name of Venus Cloacina.

CLOCKS AND WATCHES, instruments for measuring time. In early ages any device for this purpose received the general name of horologium (Gr. *ὡρολόγιον*, hour-teller), whether it was a sun dial, clepsydra, sand glass, or clock. As late as the reign of James I. of England, clocks were often called horologues. Until the 14th century the word clock was applied only

to the bell (A. S. *cluega*, Ger. *Glocke*) upon which the hour, determined by the horologe, was rung. Even at the present day the clock of Wells cathedral is called the horologe. The most ancient of all instruments for ascertaining the time of the day was probably the sun dial, although for measuring intervals or stated periods of time water vessels, called clepsydras, may have been of contemporary use. It is commonly believed that the first form of sun dial was simply a column which cast a shadow of varying length and position. The earliest mention in history of a sun dial is in 2 Kings xx. 11: "And Isaiah the prophet cried unto the Lord; and he brought the shadow ten degrees backward, by which it had gone down in the dial of Ahaz." As, however, the invention of the sun dial has been attributed to Anaximander, about 200 years later, there is some doubt as to the meaning of the word which has been translated dial, for in the same passage the word degrees has the same derivation. But the instrument referred to could hardly mean anything else than a sun dial of some form, as otherwise the passage would have no significance. At Rome, the first sun dial is said to have been erected by L. Papius Cursor, 292 B. C. Another was placed near the rostra about 30 years after by the consul M. Valerius Messala, who brought it from Sicily during the first Punic war. The first form of horologe which measured time by mechanical means was the clepsydra or water clock, but the date of its introduction cannot be traced. It is believed that it was used before the sun dial in China, Chaldea, and Egypt. (See CLEPSYDRA.) Sand glasses took the place of clepsydras in the early part of the Christian era, but the date of their earliest use is uncertain. The candle clock of Alfred the Great, and its conversion into a lantern by means of a translucent horn cover, by which he divided the day into three equal portions, one of which he devoted to religion, one to public affairs, and the third to rest and recreation, is familiar to most readers. The time of the introduction of wheel clocks moved by weights cannot be fixed with any more certainty than that of clepsydras. From the time of Archimedes, 220 B. C., to that of Robert Wallingford, abbot of St. Albans, in 1326, many ingenious men have been credited with the invention. To Boëthius (A. D. 510) has been accorded the honor, notwithstanding that it has been disputed whether it was a water or a wheel and weight clock which Pacificus of Verona, who lived nearly four centuries later, constructed, on the ground that the date was too early for such an invention. As, however, Gerbert, who became pope as Sylvester II., did undoubtedly construct a wheel and weight clock at Magdeburg in 996, when he was archbishop, the belief that Pacificus might also have made one a little more than a century earlier is not unreasonable. But, however much the earlier history of clocks may be involved in doubt, it is certain that clocks driven

by weights were in use in the monasteries of Europe in the 11th century. The Catholic clergy are credited with the introduction of clocks into England. They possessed much wealth, and had leisure to cultivate many of the arts, and were probably led to the cultivation of horology from the desirableness of having some means of regulating their religious services. The first Westminster clock is said to have been erected from the proceeds of a fine which was imposed upon a chief justice of the king's bench about 1290. The Exeter cathedral clock, the striking part of which is said to be still in use, was constructed before 1317, and one was made by Wallingford in 1326. The cathedral clocks of Wells, Canterbury, and Peterborough were also made about

FIG. 1.—Vick's Clock.

that time. The first clock on record which approached in accuracy of movement the clocks of the present time was constructed for Charles V. of France by Henry Vick, in 1370. In fig. 1, representing this clock, the weight is suspended by a cord wound round the barrel *b*, which carries a ratchet *d*. This ratchet, acting upon the great wheel *c* in one direction, will cause it to be driven by the weight. The great wheel *c* drives the pinion *e*, upon whose arbor or shaft is placed the wheel *f*. This again drives the pinion *i*, upon whose arbor is placed the crown wheel *j*, which in this clock forms the scape wheel, the action and office of which in the regulation of time will be described further on. This scape wheel, constant-

ly moving in one direction, gives an impulse to the pallets or levers *l l*, whenever they are brought within the range of its teeth; and this they are made to do by the backward and forward vibrations of the weighted balance *m m*, suspended by the cord *n*. These vibrations, caused by the action of the teeth in the scape wheel upon the pallets, being isochronous, or nearly so, divide the time of the successive escaping of the teeth of the crown wheel into equal parts. This balance was indeed a rudimentary balance wheel; a rim added, making it the diameter of a circle, and a hair spring in place of the cord, would have made it one. The turning of the single hand once around in 12 hours was accomplished by having the arbor of the barrel pass through the front plate *p*. A pinion upon this arbor, which turns once in an hour, pitches into the large wheel *o*, which has 12 times as many teeth as the pinion has leaves, and which will therefore revolve once in 12 hours. The appliance for winding consists of the pinion *h* at the lower part of the clock, which is made to turn the wheel *g* by means of an arbor which passes through the face of the clock, and which is squared to fit a key. The contrivance for regulating the motion of the last wheel is called the escapement, and the wheel is called the scape wheel, whether of the modern form or the old-fashioned crown wheel of Vick, used for nearly three centuries after in clocks, and for a much longer time in watches. It is the most essential part of the timepiece; and upon its adjustment, after the application of the pendulum, nearly all the study relating to the subject of horology has been expended. It is called the escapement, because each tooth of the scape wheel is allowed to escape from certain arms of the pendulum called pallets, after having been arrested during a period of time. But the performance of this clock must have been quite imperfect, although it was a marvel of mechanism in its day. It needed an escapement capable of making a more accurate division of time. It was impossible at that time, although it has since been accomplished, to cause the balance to oscillate in exactly equal spaces of time. The first instrument used for this purpose was the pendulum, which it can scarcely be doubted was employed in the early ages to measure small periods of time by simply counting its vibrations, without connecting it with mechanism. It is said that the ancient astronomers measured the duration of eclipses with it, but there is no recorded proof of its use before the discovery of Galileo at Florence in 1582, by observations upon a swinging chandelier, that a pendulum vibrated in arcs of different lengths in the same time, if the arcs were small. It has been said that a pendulum clock was made for St. Paul's church in Covent Garden by Harris, a London clockmaker, in 1642; but this must be an error, or the controversy could never have taken place between Dr. Hooke and Huygens, who is now univer-

sally admitted to have been the first not only to apply the pendulum to clocks, but to demonstrate the mathematical principles involved. A pendulum which oscillates in an arc of less than 10° may have that arc diminished without sensibly affecting the time; but when it moves through larger arcs the time will be sensibly increased, although not in proportion to the increase of the arc. It was demonstrated by Huygens that if the oscillations were made in the curve of a cycloid, they would occupy the same time whether the arcs were small or large. A simple pendulum may be defined to be a particle of matter suspended by a right line devoid of weight, and oscillating by the force of gravity about a fixed point, called the point of suspension. It follows, therefore, that a truly simple pendulum can only exist in the imagination. The nearest approach to it is a lens-shaped bob, made of the densest matter, as platinum, suspended by a fine steel wire. But it is evident that the particles of matter in the bob which are nearest the point of suspension will tend to oscillate oftener than those at a greater distance, and therefore to accelerate the motion, while those which are furthest will tend to retard it. There will therefore be a certain distance from the point of suspension which will divide those particles which are moving slower than natural from those which are moving faster, which may be designated the centre of oscillation of the system. If all the matter in the pendulum could be collected in this point, the time of vibration would not be changed. The length of a pendulum is understood to be the distance between the point of suspension and the centre of oscillation. The centre of oscillation is generally below the centre of gravity, and within the pendulum; but it may be entirely beyond it, as in the metronome. The length of a pendulum which oscillates in a given time may be ascertained from the laws of falling bodies. If it moves in a small circular arc, the time of one oscillation is to the time a body occupies in falling freely half the length of a pendulum as the circumference of a circle is to its diameter. It having been demonstrated that the spaces through which a body falls by the force of gravity are in proportion to the square of the time occupied in falling, therefore the time will be equal to the ratio of the circumference of a circle to its diameter (which is 3.14159) multiplied into the square root of the quotient arising from dividing the length of the pendulum by twice the distance through which a body will fall in one second, which in the latitude of Washington is about 16.08 ft. Thus: $\text{Time} = 3.14159 \times \sqrt{\text{length} \div 32.16 \text{ ft.}}$; from which all calculations as to the number of wheels in the train, the distance through which the weight should descend, &c., may be made. From the above equation, by a very simple algebraic process, the following is derived: $\text{Length} = \text{square of time} \times 32.16 \div 3.14159^2$; therefore the length of a pendulum is in propor-

tion to the square of its time of oscillation. The length of a pendulum which oscillates in one second in the latitude of Washington will be found by the following equation: $L = 1^2 \times 32.16 \text{ ft.} \div 3.14159^2 = 39.1 \text{ in.}$ If the pendulum is required to oscillate once in two seconds, it must be four times the length of a seconds pendulum, because the square of twice the time = 4. As it is necessary in a good clock to have the pendulum always of the same length, a difficulty was encountered on account of expansion and contraction from heat and cold. This was obviated by using in its construction two different materials having different degrees of expansion. Such pendulums are called compensation pendulums, and are principally of two kinds, called mercurial and gridiron. The bob of the mercurial pendulum is made of a hollow

FIG. 2.—Huygens's Clock.

cylinder of glass or iron containing mercury, whose expansion tends to shorten the distance of the centre of oscillation, while the expansion of the rod tends to lengthen it. The gridiron pendulum is usually constructed of iron and brass, whose unequal contractions cause the bob to remain during varying degrees of temperature at the same distance from the point of suspension.—The clock constructed by Huygens is represented in fig. 2. The train of wheels resembles that in Vick's clock, with the exception of having two crown wheels, with different-shaped teeth, and a train of wheels behind the dial and in front of the plate for the purpose of turning both hour and minute hands around a common centre. This train of wheels for moving the hands has precisely the same disposition as that now in use for

clocks and watches, which is represented in fig. 16. The fork *n*, moved by the pendulum *p*, takes the place of the balance in Vick's clock, and by its more isochronous vibrations produces a more accurate escapement. The pallets *l l*, carried by the verge, act upon the crown scape wheel *k*, in a similar manner as in Vick's clock. The arbor of the wheel *g* passes through the front plate, and carries a disk upon which there are 60 divisions. As this wheel turns around once in a minute, each division marks a second, and an index placed upon the dial, at the edge of an opening in it, measures the divisions as they pass. A seconds hand could have been placed upon the arbor in place of the disk, and caused to turn in front of a graduated circle in the manner now employed. The verge and crown wheel escapement which Huygens employed made it necessary to use short pallets, in order to prevent too much recoil, and consequently the use of a short pendulum vibrating in a large arc. Thus there was the unavoidable introduction of more or less error, which he sought to correct by the use of cycloidal cheeks against which a flexible pendulum was made to swing, and thus to carry the bob through a cycloidal curve. But although the theory was an illustration of Huygens's genius, it was found not to be applicable in practice, and the solution of the difficulty was more easily found by making the pendulum longer and the bob heavier, and causing it to swing in a smaller arc. The application of an escapement by which the pendulum was only required to oscillate in a small arc was accomplished by Dr. Hooke, an English contemporary of Huygens, by means of a pair of anchor-shaped pallets moving in the plane of a spur wheel having ratchet teeth, instead of using a crown wheel. This escapement produces a recoil, and is usually called the recoil escapement. It is shown in fig. 3.

When the pendulum swings to the left it lifts the pallet *a* from the upper face of the tooth *t*, which has now passed by, while the pallet *b* has also moved to the left, meeting the tooth *t'*, and by the momentum of the pendulum producing a recoil till it returns and allows the tooth to move on, giving at the same time the pallet an impulse, the pendulum swinging to the left until the pallet *a* is brought within reach of the tooth *c*, which strikes it before the pendulum has attained the limit of its vibration, thus producing another recoil of the scape wheel, which lasts

Fig. 3.—Recoil Escapement of Hooke.

till the pendulum begins to return and lift the pallet away. The impulse faces of the pallets are convex; theoretically they should be concave, but on account of friction the convex form has been found to answer the purpose better. This recoil or anchor-pallet escapement was succeeded by what is called the dead-beat escapement, invented by Graham about 1720, and which is the one now in general use for clocks, and with but little modification for watches. It is represented in fig. 4. When the pendulum swings to the right the tooth *a* escapes from the pallet *b*, while the tooth *c* is brought against the pallet *d*; but a portion of the exterior surface of this pallet, and also the interior surface of *b*, are arcs drawn from the centre *d*; and upon being struck by the teeth of the scape wheel in the direction of *d* no recoil is produced, neither is there any impulse given to

Fig. 4.—Dead-beat Escapement of Graham.

the pallet until the pendulum swings far enough to the left to bring the tooth upon its impulse face. When the pendulum attains the limit of its vibration to the left, the same dead beat is made upon the circular inner face of the pallet *b*, to be followed by an impulse upon the impulse face when the pendulum has again returned far enough to the right. For the purpose of avoiding friction, and for other reasons of which the limits of this article exclude a statement, it has been found that the teeth should be made to fall upon the dead face of a pallet as near to the angle which divides it from the impulse face as possible. There is a tendency in the dead-beat escapement to gain time as the arc of vibration of the pendulum decreases, whereas the tendency in the recoil escapement is to lose. The further the pallets are from the centre of motion, the greater will be the distance traversed over them by the teeth, and consequently the greater the friction; therefore the best clock makers place them as near the centre of motion as circumstances will allow, the usual practice being to have them describe an arc whose radius is equal to that of the scape wheel, and to have the dead faces embrace $10\frac{1}{2}$ teeth, or one half tooth over one third the number in the wheel. There is one other form of escapement, often used in turret clocks, called the pin-wheel escapement, shown in fig. 5. The invention is ascribed to Lepaute of Paris in 1755. The form usually described has the pallets placed on opposite sides of the scape wheel; but that is unnecessary, and the construction represented in the figure exhibits the plan better. In the relative position of the pallets and pen-

dulum the action of the pins is downward on both pallets, which have the impulse faces cut to nearly the same angle, the one on the shorter and outside arm being rather the more oblique when they are to receive the pins on a level with the axis of the scape wheel. It will be observed that the pallets may be made to receive the pins at any part of the revolution of the wheel by changing their position with the pendulum; and it is also evident that the form of the pins and pallets may be such as to

Fig. 5.—Pin-wheel Escapement of Lepaute.

either produce a recoil of the scape wheel or a dead beat. Another kind are called gravity escapements, because the impulse is not given to the pallets directly by the action of the train weight, but by another weight or spring which is caused to act for a sufficient space of time at every beat of the pendulum. There are several forms of gravity escapements, as Mudge's, Cumming's, Hardy's, Kater's, Bloxam's, and others.—In order that a timepiece may be kept running, there must be a contrivance for winding up the weight or spring. As it is evident that this must be done without reversing the motion of the train, there has to be provided an arrangement for turning the barrel backward without turning the great wheel. This is effected by means of a ratchet wheel, which is prevented by a click from moving on the great wheel in the direction of the going of the train, but is free to move in the contrary direction. Without some further contrivance, however, than what is necessary to prevent the great wheel from being turned back, the clock would soon stop, because the propelling power is taken away during the winding. Such a contrivance is called a main-
taining power or going barrel, the principal form of which in present use is Harrison's main-
taining spring and ratchet, or going barrel. The oldest of all is Huyghens's endless chain shown in fig. 6, which is so contrived as not to take the weight off the barrel during the winding. By pulling down the small weight the large weight is raised without taking the tension of the cord off from the going wheel at all. The pulley may be placed upon the arbor of the great wheel of the striking part, which must then be attached to it by a ratchet and click. Harrison's going barrel is represented

Fig. 6.—Huyghens's Endless Chain.

in the train of wheels in a clock shown in fig. 7. The weight moves the great wheel *c* through the spring *d*; but during winding the smaller ratchet is turned to the right, taking off the weight, while the spring, acting against the larger ratchet, impels the great wheel a sufficient time to keep it going, and thereby to maintain the motion of the scape wheel and the impulse of its teeth against the pallets. Common clocks, many of them keeping good time, are now made to be driven by a main spring instead of a weight, in the manner of a watch. Being portable, and occupying less space, they are more convenient and cheaper; but the best clocks, used for regulators, are driven by weights.—It will now be proper to describe the train of wheels and principal parts of a clock. The train comprises those wheels through which the motive power, the weight or spring, exerts its force upon the pallets connected with the

pendulum. These wheels are made to act upon each other by means of pinions, which are a kind of small cog wheels. The cogs of the wheels proper are called teeth, while those of the pinions are called leaves. The axis upon which a wheel or pinion turns is called the arbor. The train of wheels in a good modern eight-day clock generally consists of four. In fig. 7, *a* is the first or great wheel, upon whose arbor is the barrel over which the cord passes to which is suspended the weight. The second or centre wheel, *b*, whose pinion *c* is driven by the great wheel, always turns round once in an hour, and is therefore made to turn the minute hand. It drives the pinion *e* of the third wheel *d*, which again drives the pinion of the scape wheel *f*. This last is the fastest-going wheel in the train, and is the one that acts upon the pallets connected with the pendulum. The usual number of teeth in the

Fig. 7.—Train of Wheels in a Clock.

pendulum. The usual number of teeth in the

scape wheel is 30, and if the pendulum is 39.1 inches in length, it will revolve once in a minute, because one tooth will escape at every double vibration (sometimes called a complete vibration), or every two seconds. If the pinion has 7 leaves, and the third wheel, which drives it, has 56 teeth, the latter will revolve once in 8 minutes; and if its pinion has 8 leaves, each leaf will pass a certain point every minute; and therefore, if the centre wheel has 60 teeth, it will revolve once in an hour. If the pinion of the centre wheel has 8 leaves, and there are 96 teeth in the great wheel, the latter will turn round once in 12 hours. This arrangement formerly existed in clocks before the use of the minute hand, but since then wheels separate from the train have been used to move the hands at the proper rate. In the engraving a back view of the wheels is given, not placed in relation to each other just as they are when in actual use, but every wheel, following in order from below upward, placed behind its predecessor, for the purpose of showing the pinions. The wheels may be arranged in this way, but they are generally placed alternately in front of and behind each other, for economy of space. The second wheel, as has been stated, moves the minute hand. The pinion by which the great wheel drives it is called the centre pinion. This is on the back side of the wheel, but it carries another pinion in front, called the cannon pinion, which is placed on the arbor so that it may be turned by using a certain amount of force, an operation which is required in setting. It is upon a tubular barrel of this cannon pinion that the minute hand is placed. The cannon pinion has a certain number of leaves, which play into a wheel having, we will say, four times as many teeth, which latter has a pinion with a certain number of leaves which again play into another wheel having three times as many teeth. This wheel, called the hour wheel, will then turn round once in 12 hours, and upon its barrel, which is placed over the cannon pinion, the hour hand is fixed. The time during which a clock can be made to run from one winding to another, measured by the number of times the scape wheel can be made to revolve, depends upon the number of teeth in the train of wheels, the distance through which the weight falls, and the length of the pendulum. The number of teeth may be regulated by the number of wheels in the train, or by the number of teeth in each wheel and pinion. If the weight falls through a small space, the number of teeth must be increased, and this is usually done by increasing the number of wheels, which again requires the gravity of the weight to be increased. The number of teeth in the train remaining the same, the duration of running may be increased by increasing the distance through which the weight falls.—About the year 1840 Prof. Wheatstone exhibited to the royal society of London a clock dial, the hands of which were moved by a wheel acted upon by a small elec-

tro-magnet at intervals, the current being formed and broken by means of the oscillations of the pendulum of a common clock. Through this device the same time may be indicated in several distant places simultaneously. In 1848 successful experiments were made upon this principle by the United States coast survey between Cincinnati and Pittsburgh, a distance of 400 miles. A clock placed in the electric circuit recorded its beats at all the offices along the line by means of Morse's apparatus. The first clock, however, which had any of its own parts moved by electricity, was constructed by Alexander Bain of Edinburgh. In this electricity was used as a motive power in place of the usual weight or spring, and the pendulum was not only employed as a regulator, but as a motor. The bob of the pendulum was formed of a coil of wire which became a magnet at intervals of the oscillations, and, passing over the poles of permanent magnets placed near the ends of the arc of oscillation, was alternately attracted by each. In some of the clocks the two magnets were temporary, and the reversal of their poles by one of the devices used in electrical apparatus caused an alternate attraction and repulsion of the pendulum. Mr. Shepherd exhibited at the international exhibition in London of 1851 a clock in which there was an electrical gravity escapement, the pallets being raised by temporary magnets. A description of it may be found in Wood's "Curiosities of Clocks and Watches," and also in Mr. Denison's treatise.—WATCHES. The first watches must have been very imperfect time-keepers, as they were not supplied with that necessary piece of apparatus which answers the place of the pendulum in clocks, viz., the balance and balance spring, and the escapement consisted only of a verge and a crown wheel, of a similar form to that used in the verge escapement clocks. The train of wheels was moved, like that in the modern watch, by a main spring, which is a coil of ribbon-shaped, finely tempered steel, placed around the arbor of the going barrel, having one end attached to the arbor and the other to the inside of the barrel. The train of wheels in a watch is much the same as in a clock, and indeed a watch may be considered as a small clock, in which the weight and pendulum are replaced by the main spring and the balance, which latter part is composed of the balance wheel and balance or hair spring. The devices for regulating the motion of the scape wheel by means of a lever armed with two pallets, against which the teeth of the wheel are caused to exert their force, are much alike in the modern detached lever watch and a good regulator clock; but as the arc in which the pendulum swings varies but very little, while that in which the balance wheel vibrates varies considerably from different causes (the principal one being the motion given to the watch in carrying it in the pocket), it is apparent that there must be considerable variation in the mode of applying the devices.

The oldest watch escapement was the verge and crown wheel, and had the train of wheels for the going part, as well as for turning the hour and minute hands, arranged in the same way as they were in the clock of Huygens. Fig. 8 represents the old-fashioned English

verge escapement watch. At *a* is shown the barrel containing the main spring; at *b* the fusee around which the chain is wound, constructed in the form of a conical spiral to increase the leverage, as the spring diminishes in power by uncoiling; *c* is the centre wheel,

FIG. 8.—Old English Verge Escapement.

turned by the great wheel on the fusee by the centre pinion *c'*; *d* is the third, and *e* the fourth wheel, which drives the crown and scape wheel *f*. The pallets *p, p*, moving to and fro upon the verge *v*, which is the staff of the balance wheel *h*, regulate the time of escapement of the teeth. The minute hand *i* is placed upon the cannon pinion, and the hour hand *j* upon the barrel *k* of the hour wheel *l*. The arrangement for turning the hands is the same as that shown in fig. 16. The original lever escapement was invented in France by Hautefeuille about 1722, and differed much in its action from the detached lever now in general use. It is known as the rack and pinion lever, and

FIG. 9.—Rack and Pinion Lever of Hautefeuille.

is represented in fig. 9. The lever *a* has a rack, *r*, having the segment of a cogwheel at one end and pallets, *h, h*, at the other, and turning upon a pivot called the lever arbor, which is placed in the centre of the circle of which the rack is a segment. The balance wheel *d*, by its vibrations, causes the pinion to carry the rack backward and forward, and consequently moves the pallets at the other end of the lever in about the same way

they are moved by a pendulum. As, however, the arc through which the balance wheel moves is subject to considerable variation on account of the motion given to the watch in carrying, the differences in the extent of the vibrations of the pallets, and the constant lug between the rack and the pinion, caused an imperfection in the movement which was obviated by a modification invented by Mudge, which was called the detached lever, because the end of the lever which formerly carried

the rack, but which now was made in the form of a crotch or fork, was detached during certain parts of its oscillation. Fig. 10 represents the invention of Mudge, with several modifications in form which have since been devised. He placed the pallets one on each side of the lever arbor, instead of placing them at one end, opposite the fork, as in this figure. A pin in the roller which is placed over the arbor of the balance wheel, and a notch in the bottom of the fork, are so arranged that an alternate locking and detachment takes place at every escape of a tooth in the scape wheel. This detachment relieves the parts of the constant lug which existed in the rack and pinion, and allows the pallets to make perfectly equal vibrations, whether the balance wheel does or does not. This kind of lever is the one now in common use, and likely to be for a long time to come, as it is difficult to imagine any device better calculated to produce uniform motion in the train of wheels of a watch which is intended to be worn in the pocket. The top of the scape wheel *s* is moving to the right, with a constant force derived from the main spring. The pallets *a* and *b* have been moved to the left, so that *b* is out of range, and *a* within range of the teeth. The tooth *c* has locked upon the dead surface of the pallet *a*. The balance wheel is now moving in the same direction as the scape wheel, its top to the right, and its lower part, which is cut away, to the left; the pin upon the roller of the balance wheel has entered the notch in the fork; as soon as it strikes the side below

FIG. 10.—Modern Detached Lever Escapement.

the angle g it will move the fork to the left, turning the lever upon its arbor h , and consequently lifting the pallet a sufficiently to allow the tooth c to fall upon the impulse face of the pallet. In this way the lever will receive a new impulse in addition to the one it received from the balance wheel, so that before the pin gets beyond reach of the side of the notch in the fork opposite g it will be struck by it, and thus an impulse will be given to the balance wheel by which its vibrations will be maintained. It will be observed that the teeth of the scape wheel in this figure differ in shape from those in any scape wheel which has thus far been described. They are called club teeth, and their use will presently be noticed. Mudge used the old ratchet teeth. The alternate lifting and depressing of the pallets to liberate and to lock the teeth is the main object of escapements, and may be effected by three different methods: 1, by having the inclined planes on the pallets alone, and moving them by pointed teeth, as in fig. 9; 2, by having the inclined planes on the scape teeth which move against pallet edges; 3, by having the inclined planes both on the pallets and on the scape teeth, as they are in the detached lever, with club teeth on the scape wheel. In this figure it will be seen that if the scape teeth were ratchet-shaped they would still raise the pallets, because their faces are inclined to the radius of the arc in which they move, although they would not be sufficiently raised. It will be noticed, however, that the toes of the scape teeth move in a larger arc than the heels, and therefore must increase the elevation of the pallets. In this lever it is necessary to make provision against the untimely unlocking of the pallets by irregularities produced in carrying. This is done by the employment of a guard pin and two banking pins. The guard pin k is placed at the junction of the fork with the lever, at such a distance from the lever arbor h that when those two points lie in the radius of the balance wheel, or nearly so, the guard pin will be nearer the balance arbor than is the circumference of the roller; therefore a notch must be made in the periphery of the latter, on the side where the impulse pin is placed. This will allow it to pass only at certain periods in the oscillations of the balance wheel. The banking pins, $m m$, are for the purpose of preventing the lever from being carried too far by any over-impulse of the balance wheel, and their adjustment is a matter of considerable importance, and is secured with great nicety by placing them eccentrically upon screws which pass into the pillar plate, as represented in fig. 10.—Before the perfection of the lever, the cylinder, or as it is sometimes termed the horizontal escapement (fig. 11), was introduced by Graham, who invented the dead-beat escapement in clocks. A section of a hollow cylinder is cut out in such a way that its external and internal surfaces are made use of to receive the action of the teeth of the scape

wheel, while the edges are cut at such angles as to form impulse pallet faces. The mode of action in this escapement is like that of the dead-beat escapement in clocks, the outer and

FIG. 11.—Cylinder Escapement of Graham.

inner surfaces of the cylinder forming long dead pallet surfaces, so that the teeth of the scape wheel may slide over them equally well, whether the oscillations of the balance wheel are great or small. Indeed, the general principles upon which all clock and watch escapements are constructed are greatly similar; the chronometer or detached escapement differing more from all the rest than they from each other. The devices and forms are various, but they secure the same desired result by making use of nearly the same mechanical forces and appliances. The production of the chronometer or detached escapement is the work of many ingenious men, but principally of Le Roy, Berthoud, Earnshaw, and Harrison. The construction, as substantially given by Earnshaw,

FIG. 12.—Chronometer Escapement of Earnshaw.

is represented in fig. 12. There has been but little change made in it since. The balance wheel B is shown turning in the direction of the arrows, the tooth T resting

upon the stop S, which has caused it to make a dead beat. The detent, A, is a kind of latch, shown as resting against the pin which is represented opposite the letter A. Attached to its upper end is a light spring, *a*, projecting beyond its point. The scape wheel, E, is turning in the direction of the arrow by the constant action of the train of wheels. The detent is held against the pin by the spring *a'* at its lower end. A tooth, *d*, on the verge of the balance wheel, is moving with the wheel against the spring *d*, and will presently push the detent far enough back to allow the tooth T to pass by the stop, and the tooth T', which moves with greater velocity, to overtake and strike upon the impulse face of the pallet *p* before it gets beyond its reach, and thus impel the balance wheel to its full vibration. The fine spring *a* is designed to allow the pin *d* to slip by when the balance wheel returns, but to catch it and force the detent back and allow the tooth T to pass the stop when it again moves in the direction of the arrow. The hair spring of the balance wheel is not seen in the drawing, it being placed upon the hidden side of the roller.—The balance wheel of a chronometer is made to preserve a uniform time of oscillation upon the same principle as the gridiron pendulum; that is, by a combination of two metals having unequal rates of expansion and contraction by variations of temperature. The rim of the wheel is made of brass and steel, the former outside of the latter, with a number of pins screwed into it which serve as weights. The invention was made by Harrison, but the method of construction which is now generally employed was introduced by Earnshaw about 80 years ago, and consists in soldering a rim of brass around a disk of steel, and then by means of a lathe and other tools cutting away the greater portion of the disk, leaving two arms projecting from the staff, as represented

FIG. 13.—Compensation Balance.

in fig. 13. The rim is then sawed in two places, at its junction with the arms, so that during expansion the other end of the segment of the rim may be free to move toward the centre of the wheel, and thus produce sufficient compensation to prevent a change in the time of oscillation. The proper adjustment can only be accomplished by trial, which requires the employment of considerable time and skill, and constitutes one of the items of expense in a chronometer or a good watch. In regard to chronometers, little more need be said after giving a description of the escapement, and the principle of the compensation balance wheel. The escapement is the most perfect that has ever been devised for a timepiece which is to be kept in one position.

It has been attempted to use the chronometer escapement in pocket watches, but without success, great irregularities being produced by change of position, and motion consequent on carrying; but when the timepiece is furnished with a perfectly compensating balance wheel, so that its vibrations are isochronous under any change of temperature to which it may be exposed by the passage of a ship from one zone to another, and it is suspended in gimbals, as represented in fig. 14, so that, whatever angle the deck of the ship may form with the horizon, the chronometer will always maintain the same position, it becomes one of the most perfect pieces of mechanism.

FIG. 14.—Chronometer.

Its great use is in making astronomical observations, and it is especially valuable in determining longitude at sea. The first experiment with a chronometer was made in 1665, in a voyage to the coast of Guinea, by Major Holmes, with a watch made by Huygens. With this the longitude of the island of Fogo was obtained with tolerable precision. In 1726 Mr. Harrison made a chronometer which was a marvel for correct timekeeping. In 1736 it was sent to Lisbon, and corrected the reckoning on the voyage as much as a degree and a half. He was paid £500 by the English government to prosecute further experiments, which resulted in his producing an instrument so accurate that it made an error of less than two minutes in a voyage to Jamaica and back, and in obtaining the reward of £20,000 which had been offered. It is not attempted to regulate chronometers to diurnal time, it being only necessary to ascertain their rate, when the correct time can be calculated.—The train of wheels, together with the lever and balance in a modern detached lever escapement, such as is now made in the best watch factories in the United States and in Europe, is represented in fig. 15. It is placed between two plates of brass, the under, called the pillar plate, being an entire circle, while the upper plate, which is removed in the figure, may be either one quarter, one half, three quarters, or a full plate. In many European watches the upper plate is almost entirely replaced by what are called bridges—pieces which are screwed to the pillar plate, and have arms which project far enough to receive the arbors of the wheels. The barrel *b*, which contains the main spring, has the great wheel placed around it, instead of being placed upon a fusee and driven by a chain wound upon the barrel as represented in fig. 9, and which is still the construction in most English watches. Of course the tension of the spring becomes less as it uncoils; but if the coil is of considerable length the variation need not be great, and by the nice adjustment of the balance is completely counteracted. One

end of the spring is attached to the barrel arbor, the exterior portion of which is shown at *a*, and squared, to admit of winding by a key. The other end of the spring is attached to the

FIG. 15.—Train of Wheels in a Detached Lever.

inner surface of the barrel. The arbor carries a ratchet wheel, which is prevented from turning back by a click. The centre wheel *d* is driven by the action of the great wheel upon its pinion *c*, called the centre pinion. The centre wheel drives the third wheel *f*, by means of its pinion *e*, and the third wheel again drives the fourth wheel *h*, which carries the seconds hand, in a similar manner. The fourth wheel drives the pinion *i* of the scape wheel *j*, whose teeth again alternately lock and impel the pallets *l l*, which are placed on the pallet arms of the lever. The lever turns upon the pallet arbor *k*, and by means of the fork gives an impulse to the balance wheel, as has already been described. If the fourth wheel, which revolves once in a minute, has 64 teeth, and the pinion of the scape wheel has 7 leaves, that wheel will turn round once in $6\frac{7}{16}$ seconds; and if it have 15 teeth, each tooth will escape every $\frac{7}{16}$ of a second, and consequently there will be one complete oscillation of the balance wheel every $\frac{7}{16}$ of a second. If the pinion of the fourth wheel contains 8 leaves, and there are 60 teeth in the third wheel, the latter will make one revolution in $7\frac{1}{2}$ minutes. Again, if the pinion of the third wheel has 8 leaves, and the centre wheel has 64 teeth, the latter will revolve one eighth as often as the third wheel, or once in an hour. It is not necessary that these proportions should be fixed, but the number of teeth in the train must be such that there will be a certain ratio between the number of teeth in the centre wheel, which revolves once in an hour, and the number of leaves in the pinion of the fourth wheel, which revolves once in a minute; and the teeth in the fourth wheel, the leaves in the pinion of the scape wheel, the teeth in the latter, and the vibra-

tions of the balance wheel, must have certain relative proportions to each other. The hour hand is moved by a train of two wheels and two pinions, placed on the outer side of the pillar plate, and beneath the dial. The arrangement is represented in fig. 16. The cannon pinion is placed on the arbor of the centre pinion, and fits spring-tight, so that it may be moved at pleasure in setting the minute hand. Above the pinion proper there is a barrel upon which the minute hand is placed. If the cannon pinion, which is here hid from view, has 12 leaves, and the wheel into which it pitches has 42 teeth, the latter will revolve once in 4 hours. If, again, the pinion of this wheel has 14 leaves, and the centre wheel has 42 teeth, the latter will revolve one third as often, or once in 12 hours. One of the modern arrangements for winding and setting the watch is also represented in this figure. A crown wheel is placed upon the end of a shaft which

FIG. 16.—Hand Wheels and Stem Winder.

passes through the stem. This wheel moves another, which is placed upon a yoke between two other wheels, one of which, the winding wheel, is held in gear by a spring, and the other the setting wheel, thrown into gear at pleasure by the pressure of a button. When one wheel is thrown into gear, of course the other is thrown out, so that the winding of the watch and the setting of the hands are done independently and without interference. An inspection of the figure will afford all the explanation that could be given in words.—The limits of this article will not allow of a description of the striking and alarm parts of clocks and repeating parts of watches, and other devices, such as for showing the day of the month, without a sacrifice of more important matter which more strictly relates to time-keeping; and as these parts can be best understood by an actual inspection of the time-pieces, the reader who may wish to become acquainted with their mode of action is advised to study the subject in that way.—Excellent watches are now made by machinery in the United States: by the American watch company at Waltham, Mass.; E. Howard and com-

pany at Boston, Mass.; the United States watch company at Marion, N. J.; the National watch company at Elgin, Ill.; the New York watch company at Springfield, Mass.; the Springfield watch company at Springfield, Ill.; and the Cornell Watch company at Grand Crossing, Ill. Watches made by this method possess the advantage of great accuracy at a comparatively small cost. All the parts in the train are made perfectly uniform, so that any particular wheel may be replaced without making any sensible variation in the running of the watch; and so of any other part. The small, fine-threaded screws which are used to hold some of the parts together are made in the most perfect manner and with wonderful rapidity by very ingenious machines, one of which is shown in fig. 17. A steel wire, *a*, is placed in

FIG. 17.—Screw Lathe.

the spindle and turned by the belt. A die, represented enlarged in the upper part of the cut, made in two sections and held in the end of a tool *b*, cuts the thread as it is pressed against the wire by a motion communicated by a lever. Previous to this, however, the wire is reduced to the precise length required by the tool *c*, which is adjusted by a gauge, and the stem of the screw is also turned down by the tool *d*. After the thread is cut, the tool *e* is brought against the wire, and the head of the screw is formed. There is an ingenious device

FIG. 18.—Slotting Disk.

for removing the screw, which is still attached to the wire by a small pedicle. It consists of two disks, represented in fig. 18, which when joined together form a series of tapped holes, made to fit the screws. One of these, being held against the point of the screw while it is revolving in the spindle, receives it, and when the end of the thread is reached the motion breaks off the pedicle, leaving the screw in the disk. When all the holes are filled, the disk is placed in an ingenious automatic machine which car-

ries, during proper periods of time, the head of each screw beneath a revolving saw which cuts the slot. A machine for cutting the teeth in wheels is shown in fig. 19. A tool called a quill, an enlarged view of which is presented

FIG. 19.—Lathe for Cutting Teeth.

in fig. 20, *a*, and which is divided into sections to receive the arms of the wheel, bearing upon its exterior the rim, is fed with from 20 to 40 wheels, the collection being called a stack. This quill is then placed upon a shaft which is turned by a graduated wheel having notches in its rim to correspond with the number of teeth in the wheel. This wheel is stopped at each notch by the click *c*, whereby the quill holding the stack of wheels is fixed, and in such a position

FIG. 20.—Enlarged View of Cutter.

respecting the tool which is carried by the arbor *b*, that a groove may be cut between two teeth in a radial direction, or any other which may be required. The arbor of the cutting tool is carried backward and forward by means of a slide *d*, worked by a lever *e*, by which means the tool is carried along the whole length of the stack of wheels, cutting a notch in each, and thereby forming the teeth. Club-tooth scape wheels require for their cutting several different forms of tools. These are

placed upon arbors which are made to revolve about a common centre, in the manner of a revolving firearm. Many other labor-saving machines are in use whereby great accuracy is attained at a comparatively small cost. The polishing of the leaves of pinions and the teeth of wheels, and the grinding of the faces of the pallet stones to their proper angles, are processes that are performed with much greater facility and accuracy by the use of machinery than by hand.—Most of the internal parts of clocks and watches, except the pinions and arbors, are usually made of brass, because of its ductility at ordinary temperatures. From its resemblance to gold it can be readily and cheaply covered with a frosting of gilt to protect it against corrosion. An alloy of nickel is used instead of brass in many of the Swiss and American watches, which in being finished passes through a process called damaskeening, by which wavy lines resembling those on Damascus swords are produced on the surface. Dials for watches, and also for clocks, are made by fusing enamel upon a thoroughly cleaned disk of copper, and then grinding down the surface evenly upon a stone, after which it is again subjected to enough heat to glaze it. The required circles are then inscribed upon it, and the proper divisions are made for the figures, which are painted on with a pencil in black porcelain paint and burned in.—Geneva, Neuchâtel, Chaux-de-Fonds, and Locle, in Switzerland, are the chief seats of watch manufacture, particularly for exportation, in Europe; but watches are made at several places in Germany and France. Liverpool has long been celebrated for timekeepers, and most of the English watches for exportation are made there.

CLODIUS PULCHER, *Publius*, a Roman demagogue, killed in 52 B. C. He was by birth a Claudius, but changed his patrician name to Clodius in order to curry favor with the plebeians. He served in Asia under Lucullus, in whose camp at Nisibis he acted the part of a mutineer, and was afterward taken captive by the pirates of Cilicia. On his release he joined the Syrians in their war against the Arabians. He led a scandalous life on his return to Rome, and was believed to have had an intrigue with the wife of Julius Cæsar, into whose house, while it was occupied by the vestals and matrons in the performance of the mysteries of the Bona Dea, during the celebration of which all males were rigorously excluded, he gained admission in the disguise of a woman. Cæsar, although he repudiated his wife on the ground that she must not even be suspected, gave evidence in favor of Clodius on his trial for the violation of the sacred mysteries. Cicero declined to defend him, and gave evidence against him. By bribing the judge, however, Clodius was acquitted. Supported by Cæsar, Pompey, and Crassus, he was elected tribune in 59, and used his power to drive Cicero into exile for one year, after which he was recalled to Rome, in spite of the opposition of Clodius.

He also managed to make Cato leave Rome, by sending him on a mission to Cyprus. Having degraded himself as a tool of the triumvirs, he aimed at the supreme power, rallied around him the worst characters of Rome, insulted Pompey, and after having taken every means to bring disgrace upon himself and upon Rome, he was finally murdered in an affray with his political rival Milo, a circumstance which has acquired great celebrity from Cicero's oration in defence of the murderer. The mob was infuriated at the death of their favorite, and Pompey was appointed sole consul to restore order. The first wife of Clodius was a sister of Lucullus, and his second the notorious Fulvia.

CLOELLA, a Roman maiden, who according to the legend was one of the hostages delivered to Porsena when he withdrew from the Janiculum, terrified by the threats of C. Mucius Scævola. The story is that she swam across the Tiber and effected her escape, but was sent back to Porsena by the Romans. Porsena in admiration of her courage presented her with a horse richly caparisoned, and allowed her to make a selection from the other hostages and return with them to Rome. She chose those who were of tender age and most likely to suffer from captivity. An equestrian statue which stood in the *via sacra* at Rome was supposed to have been erected in her honor.

CLOGHER, a decayed episcopal town of Ireland, in county Tyrone, situated on the Laung, a tributary of the Blackwater, 80 m. N. W. of Dublin; pop. about 400. The see of the Anglican bishop has lately been united to that of Armagh; the bishop of the Roman Catholic diocese of Clogher resides at Carriackmacross, in county Monaghan. St. Patrick is said to have been the first bishop of Clogher, in 444.

CLOISTER. See **MONASTERY**.

CLONFERT, one of the oldest Irish bishoprics, deriving its name from the convent of Clonfert or Clonefort, in the county and 42 m. E. of Galway, founded in the latter part of the 6th century by St. Brendan. The present residence of the Roman Catholic bishop is at Loughrea; the Anglican diocese has been united to that of Killaloe. Clonfert, formerly called a city, contains an ancient episcopal palace and cathedral and a few huts.

CLONMEL (Irish, vale of honey), a town and parliamentary borough of Ireland, in the counties of Waterford and Tipperary, on the Suir, 90 m. S. W. of Dublin, and 25 m. N. W. of Waterford; pop. in 1871, 9,484. It is finely situated in a picturesque valley, nearly shut in by mountains. Most of the town is built on the N. or Tipperary side of the river, which is crossed by three stone bridges. The main streets are handsome and well paved. Gas is generally used, and the supply of water is abundant. The best houses are of limestone quarried in the vicinity. There is a handsome new court house, a county jail, barracks for infantry and artillery, a military hospital, a club house, a fine parish church, a well endowed

grammar school founded in 1685, a lunatic asylum, workhouse, infirmary, fever hospital, dispensary, two orphan establishments, and other charitable institutions. It has a considerable trade in grain, cattle, butter, and bacon; the buttermarket is a commodious building. There are general fairs in May and November, and also special fairs every alternate month, chiefly for cattle. Clonmel is said to have been fortified by the Danes. It was taken by Cromwell in 1650, and the fortifications demolished.

CLOOTZ, Jean Baptiste, baron, known under the name of ANACHARSIS CLOOTZ, a French revolutionist, born near Cleves, Prussia, June 24, 1755, guillotined in Paris, March 24, 1794. He was educated in Paris, and his wealth permitted him to devote himself to his visionary schemes of social and political regeneration. Under the name of Anacharsis he visited Germany, England, Italy, and several other countries of Europe to preach philanthropical doctrines, the aim of which was to unite all nations in one brotherhood. When the French revolution broke out, he returned to Paris. He had already called himself the spokesman of the human race, and he now proceeded to officiate as its ambassador. Gathering around him as many specimens of the different foreign nationalities as he could find in Paris, he marched up with them to the national assembly, and delivered an address demanding for the foreigners in Paris the right of participating in the celebration of the anniversary of the taking of the Bastille. He showed the utmost devotion to the cause of the revolution, and contributed 12,000 livres for the public defence. After Aug. 10, 1792, he repaired to the legislative assembly, where he indulged in violent attacks against monarchy and religion, insisted upon a price being placed upon the heads of the duke of Brunswick and the king of Prussia, and finally offered to raise at his own expense a legion of Prussians. Created a French citizen by a decree of the legislative assembly, he was elected to the convention by the department of Oise, and became conspicuous by his eccentricity and his intense hatred of crowned heads. In spite of all this, he was suspected by Robespierre, who had no confidence in a rich and titled revolutionist. He caused Clootz to be expelled from the society of Jacobins, implicated him in the accusation of Hébert and his companions, and, although no evidence of his guilt could be produced, sentence of death was passed upon him. When brought to the place of execution, he asked to be beheaded the last, "in order," as he said, "to be able to verify certain principles, while he saw the heads of his companions fall." Calmly ascending the steps of the scaffold, he protested against his sentence, made a final appeal to the human race, and received the fatal blow with unflinching courage. He left some strange writings: *La certitude des preuves du Mahométisme*, *L'orateur du genre humain*, and *La république universelle*.

CLOQUET. I. Hippolyte, a French physician, born in Paris in 1787, died there, March 3, 1840. He was for 15 years the most distinguished private teacher of anatomy of his time, but fell into a state of complete mental debility. Among his works, long highly valued, are treatises on descriptive and on comparative anatomy, on odors and the sense of smell, &c. —His son ERNEST (1818-'55) was from 1846 physician to the shah of Persia, receiving the title of privy councillor, and was also accredited as minister of France at his court. **II. Jules Germain**, baron, a French physician, brother of Hippolyte, born in Paris, Dec. 18, 1790. He commenced the study of medicine at an early age, earned distinction in anatomy and surgery while very young, became one of the most eminent surgeons in the world, and was for many years professor of surgery in the faculty of Paris. Besides his great work on human anatomy (3 vols. large fol., with 240 plates, 1821-'31), he wrote numerous important works on hernia, on calculi and the diseases of the urinary organs, on the preparation and construction of skeletons, on the existence and disposition of a lachrymal apparatus in serpents, and on the anatomy of intestinal worms. Several of his dissertations obtained prizes from the academy of sciences and other learned societies. He invented many new surgical instruments, and several important methods of performing surgical operations. He also introduced improvements in the art of modelling anatomical preparations in wax; and many of his own exquisite preparations are preserved in the anatomical museum of the medical faculty of Paris. In 1831 he obtained by public competition the chair of clinical surgery of the faculty of Paris; in 1855 he succeeded Lallemand as member of the academy of sciences; in 1860 he was made commander of the legion of honor, and in 1867 a baron. Besides his professional works, he published *Souvenirs de la vie privée du général Lafayette*.

CLOSSE, Raphael Lambert, the great Indian fighter of colonial Canada, born at St. Denis de Mogres, near Tours, France, killed at Montreal, Feb. 6, 1662. He came out with Maisonneuve in 1642, and was made sergeant major of the garrison of Montreal, acting in time of peace as notary also. The exposed position of this settlement made his office one of importance, and he soon grasped the theory of Indian fighting. He trained his men as sharpshooters, and armed them with musket, pistol, and sword. Each was to pick his man, bring him down with a musket ball, then rush on and take another with a pistol, and then come to close quarters with the sword, taking to the cover of trees when possible. By these tactics, when he once set out with 20 men to rescue four who were besieged in a redoubt at Point St. Charles, though he lost four men at the first fire, he killed 32 with his survivors, and routed the hostile force. On July 26, 1651, with only 16 men, after a fight that

lasted all day, he routed a party that had penetrated to the Hôtel Dieu or hospital in Montreal. On Oct. 14, 1652, he engaged a force of 300 Iroquois near the fort, and, protecting his party of 34 by an old hut, routed the enemy completely, having killed 50 and wounded 37 of them, losing only one man killed and one wounded. In 1655 he acted as governor of Montreal, in the absence of Maisonneuve. On Feb. 6, 1662, he was sent out with 12 soldiers to rescue some workmen attacked by the Iroquois; but being deserted by his servant, and his pistols missing fire, he and three of his party were killed. He left a young widow, Elizabeth Moyen, who had been made an orphan by the Indians. The fief of St. Lambert had been granted to him in 1658 as a reward for his services, and in 1672 another was bestowed on his widow. As a mark of respect to him, St. Lambert street, Montreal, as well as his fief, were named after his patron saint.

CLOT, Antoine, popularly known as **CLOT BEY**, a French physician, born near Marseilles in April, 1795, died there in 1868. He studied at Montpellier, became a surgeon at the principal hospital of Marseilles, and in 1822 chief surgeon of the Egyptian army. At the instance of Mehemet Ali he founded at Abu-Zabel, near Cairo, a medical school and hospital, schools for the acquirement of the French language, for apothecaries and veterinary surgeons, and for midwives. In 1832 he received the title of bey, being the first Christian thus honored without being required to change his religion. In 1836 he was made chief physician of the general staff and director of the whole medical administration, with the rank of general. The institutions over which he presided were removed in 1837 to Cairo; and though he was opposed by native fanatics, who even sought to murder him, he effected many improvements in medical education and organization, and displayed great skill and devotion during the prevalence of the cholera. In 1849, after the death of Mehemet Ali, he returned to Marseilles, and presented his Egyptological collections to the French government. He wrote extensively on the cholera and the plague, and among his works are *Aperçu général sur l'Égypte* (2 vols., Paris, 1840) and *Méhémét-Ali, vice-roi d'Égypte* (Marseilles, 1862).

CLOTAIRE. I. King of the Franks, the youngest son of Clovis and Clotilda, born in 497, died in 561. On his father's death in 511 he received as his kingdom a part of Neustria, the capital of which was Soissons, while his brothers, Clodomir and Childebert, were kings at Orleans and Paris, and the eastern part of the Frankish empire, Austrasia, was in the hands of Theodoric, the eldest son of Clovis. When Clodomir was killed in 531, Clotaire murdered two of his nephews to get possession of the kingdom of Orleans. His son Chramne having revolted against him, he ordered him to be burned alive with his wife and children. After the death of his brother

Childebert, and of Theodoric's grandson, Clotaire found himself in possession of the whole Frankish empire. He reigned after this but three years; and on his death the empire was divided among his four sons, Charibert, Gontran, Chilperic, and Sigebert. He was buried in the church of St. Médard at Soissons. **II.** King of the Franks, born in 584, died in Paris in 628. He was only four months old when, at the death of his father Chilperic, his guardianship was assumed by his mother Fredegonda. A protracted and ferocious war broke out between her and her rival Brunehaut, who governed Austrasia and Burgundy in the name of her grandsons. After many vicissitudes, Brunehaut was delivered into his hands by the nobles of Burgundy in 613, and was put to death in the most barbarous manner, her grandsons being already dead. Thus Clotaire II., being the only surviving Merovingian prince, was proclaimed king of the whole empire founded by Clovis, and increased by the conquests of his sons. He was succeeded by his son Dagobert I.—Two other Merovingian princes of the same name bore the title of king: **CLOTAIRE III.**, in the 7th century, under the guardianship of Ebroin as mayor of the palace; and **CLOTAIRE IV.**, some 50 years later, under Charles Martel. Both were among the most obscure of the *rois fainéants*.

CLOTHO, the youngest of the three Parcae or Fates, daughter of Jupiter and Themis, or of Erebus and Night. Clotho held the distaff and spun the thread of life, whence her name Κλωθω, "I spin." She was represented wearing a crown with seven stars, and a many-colored robe.

CLOTILDA. I. Saint, the wife of the Frankish king Clovis, born about 475, died in Tours, June 3, 545. While an infant, her father, mother, and two brothers were murdered by her uncle Gundebald, king of the Burgundians, who spared her life on account of her extreme youth, and who even attended to her education. Her father had been an Arian; but she and her elder sister Chrona, who became a nun, were educated in the Roman Catholic faith of the mother, and Clotilda became a great favorite among the bishops of Gaul. Through their agency she was married to Clovis in 493, to whose conversion she greatly contributed. When the power of her husband was firmly established in the country north of the Loire, she incited him to attack the Burgundian king in order to avenge her father's death. Clovis yielded to her entreaties, but did not follow up the victory he had won near Langres, and was satisfied with making Gundebald his tributary. After the death of Clovis (511), however, the queen prevailed upon her three sons, Clodomir, Childebert, and Clotaire, to renew the war against Sigismund, the son of the murderer. This unfortunate prince was taken prisoner, dragged to Orleans, and with his wife and children thrown into a well. The war in the mean time continued, and after a protracted struggle Clotilda had the satisfaction of seeing Burgundy

in the hands of her sons Childebert and Clotaire. She spent the latter part of her life in Tours, near the tomb of St. Martin, became noted for her piety, founded several monasteries and churches which acquired great celebrity, and was canonized by the church of Rome. According to her desire, she was buried in the church of Ste. Geneviève, Paris, built by Clovis. Saved from destruction during the revolution, her remains are now in the church of St. Leu, and a new church has been built in her honor. Her marble statue is in the Luxembourg.—See *Vie de Sainte Clotilde*, by Mme. de Renneval (2 vols., Paris, 1809). **II.** A daughter of the preceding, died in 531. Her husband, Amalaric, king of the Visigoths, ill-treated her, and she was insulted by the populace because she declined to become a convert to Arianism. Her brother Childebert, on receiving her veil stained with the blood of a wound inflicted upon her by her husband, invaded Amalaric's territory, despoiled the churches of Narbonne, and took her with him to Paris; but she died on the way.

CLOTILDE DE SURVILLE. See SURVILLE.

CLOUD, a N. county of Kansas, intersected by Republican and Solomon rivers; area, 720 sq. m.; pop. in 1870, 2,323. The chief productions in 1870 were 21,794 bushels of wheat, 76,105 of Indian corn, 4,735 of oats, 11,609 of potatoes, 3,224 tons of hay, and 25,871 lbs. of butter. There were 894 horses, 842 milch cows, 2,123 other cattle, 614 sheep, and 637 swine. Capital, Concordia.

CLOUDS, bodies of vapor in the atmosphere. From the surface of the earth and of the waters aqueous vapor is continually ascending into the atmosphere, where it remains in an invisible state so long as the air is not saturated with moisture. Its capacity to retain this vapor is limited, but varies with its temperature; the greater the warmth, the more the particles of vapor are expanded and carried into higher regions. Cold condenses the particles, their specific gravity is increased, and they appear in visible form. (See Dew.) Saturated to the utmost, the atmosphere cannot contain, it is estimated, more than 6 to 7 inches of water, diffused through it in an invisible state, at one time. But the diffusion of vapor is never uniform, and the temperature also varying in different portions of the atmosphere, there ensues the greatest diversity in the conditions of the moisture contained in these portions. Where it is not too abundant for the existing temperature, it is all dissolved, and the appearance is presented of the clear, blue, invisible ether. Where the moisture is in excess for the temperature, it is seen in the form of clouds, thin and fleecy if the air is but slightly sursaturated, but dark and lowering if new accessions of moisture or reduction of temperature increase the difference between the moisture present and the capacity of the air to retain it. Thus the conditions are seen that cause frequent changes in the appearance

of the clouds; and it is understood how clouds filled with moisture, like those gathered by the Etesian winds as they sweep over the Mediterranean, are dispersed in thin air as they strike the hot rays reflected from the burning sands of Sahara; and how those similarly charged with moisture by the sweeping of the trade winds across the Atlantic shed this in copious showers as they strike the cold summits of the Cordilleras. The formation of a cloud by cold and its dispersion by heat are beautifully exhibited at the Table mountain, Cape of Good Hope. As the wind from the southern ocean strikes the rocky slopes of the mountain and is diverted upward into the colder regions of the atmosphere, a dense white cloud is evolved, which, reaching but little above the mountain, spreads over its summit and is carried down the other side. It marks the course of the wind, "plunging down with the violence of a cataract," as described by Sir John F. W. Herschel, "clinging close to the mural precipices that form a kind of background to Cape Town, which it fills with dust and uproar." But as it reaches the warmer regions below, the moisture soon resumes its invisible state, and the cloud is only seen covering the mountain and hanging down its precipitous sides, suggesting the idea of a huge white cloth, whence its name of "table cloth." There is much difference in the height of clouds. The mean height in winter may be stated as from 4,000 to 4,600 ft., and in summer from 10,000 to 14,000 ft.; but they often have greater altitudes. Gay-Lussac, when in a balloon at a height of 23,000 ft., observed cirrus clouds at a considerable distance above him. In Ethiopia M. d'Abadie saw storm clouds at a height of only 700 ft. above the earth. Dalton asserts that in small fleecy patches they have been seen at full five miles above the surface, sailing even over the highest summits of the Andes. But in cold regions the vapors are soon checked in their ascent by condensation. Wherever arrested, if the weather be calm, they settle down by their greater relative gravity, undergoing with change of position changes of form and appearance, until they may be at last brought to the warmer airs below, and in these dissolving and disappearing, be again lifted into the colder strata to reassume the form of a cloud. Clouds are thus no permanent collections of the same particles of aqueous vapor, but spaces in the firmament in which successive portions of vapor in the atmosphere are continually presented in visible form, to disappear and be replaced by other portions. To account for the suspension of clouds various theories have been proposed. De Saussure considered the particles of vapor to be minute hollow vesicles filled with air, from $\frac{1}{45000}$ to $\frac{1}{28000}$ of an inch in diameter, and he has been supported by Halley, Kratzenstein, and Brevais. One reason offered in favor of the vesicular theory is the fact that rainbows are not produced when the sun shines on clouds or steam, as it was thought they would if the

particles were globules of water; but Sir J. Herschel offers the explanation that the globules may be as minute as the lengths of light undulations, and would not therefore, by refraction or reflection, form the solar spectrum. It appears, moreover, that as long ago as 1847 ("Philosophical Transactions"), Dr. A. Waller disproved the existence of vesicles by projecting steam upon the surface of Canada balsam and examining the particles with a microscope, when it was found that they were not hollow. Assuming this to be a fact, the suspension of clouds in the air is not difficult of explanation when we reflect that, as Prof. Stokes has demonstrated, a globule of water $\frac{1}{10000}$ of an inch in diameter falls through the air with a velocity of only $\cdot 067$ of an inch per second, a motion which is inappreciable when compared to the upward movement which the air generally has in large clouds.—The various forms in which clouds present themselves are described after the nomenclature introduced by Mr. Luke Howard in the "Askesian Lectures," 1802 (published in vols. xvi. and xvii. of the "Philosophical Magazine"). He recognizes

Fig. 1.—Cumulus.

three primary modifications, the cumulus, stratus, and cirrus; and intermediate between these, into which they blend, three other forms, the cumulo-stratus, cirro-stratus, and cirro-cumulus; and lastly, the nimbus, resulting from the others confusedly intermixed.—The cumulus is the summer day cloud. About sunrise it is seen to collect by the gathering of the small specks of cloud, which are the scattered night mists, and which, accumulating, present the appearance of distant rounded hills covered with snow. In calm weather it is obviously formed from the columns of vapor that rise irregularly from the surface, invisible below, but brought into view above, as the particles reach the stratum of the atmosphere already at its dew point. There the vapors, arrested in their ascent, form piles of clouds of hemispherical shapes, the apparently flat bases of which mark the level where hygrometric saturation commences. As with the increasing warmth of the day more vapor is carried upward, these piles of clouds increase in height and density. They obscure the rays of the sun, by which, however, they may be dispersed before the decline of day, or

they may be gathered and condensed by cool winds, preparatory to returning their moisture to the earth in the form of rain.—The stratus is the cloud of night and of winter, though not limited to these periods any more than the cumulus is to that of the day. As the day cloud is produced by the ascending vapors, that of the night, called also the fall cloud, is, excepting fogs formed by exhalation, the result of their descent, their settling down in horizontal layers or strata. This form of cloud is

Fig. 2.—Stratus.

at times suddenly produced, overspreading the heavens in a few minutes, by the temperature of the air falling by radiation or by diminished atmospheric pressure. It falls to a lower level than other clouds, creeping along the valleys at night in the form of mists and fog, and vanishing with the return of day. In winter it continues as an overhanging cloud sometimes for several successive days. The smoke fogs are one form of the stratus; at night settling down to a lower level, as if each smoky particle by radiation of heat collected dew, and sunk by increase of weight.—The cirrus is a cloud

Fig. 3.—Cirrus.

of feathery form, and in wisps of diverging fibres. It extends in long slender filaments, and again in parallel stripes from one extremity of the heavens to the other. Its appearance often in flexuous fibres has caused the names of curl cloud and mare's tail to be applied to it. No clouds are seen so elevated as the cirri. From summits where one looks down upon the piles of cumuli, the fleecy cirri are seen floating as far off apparently in the blue ether as when

observed from the base of the mountains. Their great elevation and feathery form suggest that the vapor exists in snowy flakes, and this is rendered more probable by the occurrence of those phenomena due to reflection and refraction, as halos, parhelia, &c., most usually in these clouds and the cirro-cumulus. Traces of halos, such as are produced by the refraction of light from frozen particles, may almost always be discovered in them by careful examination with the aid of a blackened mirror. The long filamentous forms of cirrus are evidently connected with the action of currents in the air, maintaining uniform temperature along their lines, and drawing out in these shapes the residues of dissolving clouds. Variations in these currents of temperature or direction impress new forms upon the cirri. In diverging fibres, which is the true cirrus form, the cloud is supposed to indicate changeable weather, in summer rain and wind, in winter frost or snow; if the fibres have for some time continued to point in one direction, a gale of wind is looked for from that quarter.—The cirro-cumulus is often produced by the cirrus descending to a lower level in the atmosphere, and its parallel bands breaking up into the shape of small cumuli. It also appears independently of the previous existence of cirri. It floats at a high elevation, being often seen in the light of the moon through the sud and drift of the lower clouds, looking not unlike a flock at rest. Its spotted appearance has caused it to be commonly known as the "mackerel sky."—The cirro-stratus is characterized by its arrangement in long parallel lines of cloud in close proximity, straight or waving, and lying in horizontal strata. It is also seen in a long and narrow horizontal sheet, tapering toward its extremities. The name of wane cloud has been given to it, from the fibres of the cirrus waning or subsiding to produce it. Its prevalence indicates wind, rain, or snow. In the form of rows of little clouds curved in a peculiar manner, it is called the cymoid cirro-stratus, and is regarded as a sure indication of approaching storms. When seen as a thin hazy veil spreading over the sky, particularly toward night, and obscuring the sun and moon, it is one of the most certain signs of approaching rain or snow. Virgil, in the Georgics, notices this obscuration of the sun behind a cloud soon after its rise, as sure to be followed by rain. The refractions of the light of the sun and moon, producing halos and mock suns, often appear in this cloud.—The cumulo-stratus is formed by the passing of the cumulus into the nimbus, or rain cloud, though before the latter is perfected the cloud may be dispersed by evaporation, or turn back to the cumulus. It is also called the twain cloud, from the fact that two or more cumuli are often seen to join together to produce it. A single one is also sometimes observed to spread out laterally at top, till it overhangs the base in irregularly shaped protuberances. Such masses gather to-

gether, presenting a most imposing spectacle, as a thunder storm is approaching. The marginal protuberances are then seen, often shining with a strong silvery or golden light, contrasting finely with the darkness and density of the central portions of the cloud. Upon these the cirrus or cirro-stratus is sometimes formed by currents of air, causing the upper portion of the cloud to assume the curly forms of this variety, or spreading its long line horizontally across the summit.—The nimbus is that stage of cloud from which the rain falls. It usually proceeds from the cumulo-stratus, which grows darker and denser, till its blackness and threatening aspect can no longer be mistaken as a sure sign of impending rain. The blackness gives place to a gray obscurity, an evidence of a change in the disposition of the aqueous particles, and the rain falls from the cloud, which is now a nimbus. The presence of its aqueous drops gives it the distinction among clouds of being the field upon which are displayed the beautiful colors of the rainbow. The nimbus having discharged its moisture, the various forms of cloud are again seen in their several places in the sky; the cirrus in some of its

FIG. 4.—Nimbus.

modifications in the upper regions, while the fragments of the nimbus are converted into thin cumuli, which are borne along by the light winds near the surface. But if these gather again into the form of cumulo-strati, rain is likely to return.—The nomenclature of Howard is generally adopted by meteorologists. Prof. Loomis objects to the introduction of the nimbus as a distinct form, considering that it does not differ from some of the other varieties, except in the fall of rain, which is not sufficient to give it a peculiar character; for clouds do not always undergo a decided change as rain begins to fall. He remarks upon the occurrence, familiar to all who have lived in the vicinity of the great lakes, of a sheet of cloud continuing during a large part of the winter season to overcast the sky, from which snow is frequently emitted for days in succession, without change or apparent motion in the cloud itself. This variety, including all clouds which cover the heavens with a nearly uniform and unbroken sheet, he places in the division stratus, thus supplying a deficiency in the European

classification, at least in its adaptation to American meteorology. ("Journal of Science," vol. xli., p. 325.)—Prof. André Poëy, late director of the observatory at Havana, published a memoir in the report of the Smithsonian institution for 1870, in which he proposes a new classification, which includes only two classes or types in place of the three of Howard, rejecting the stratus on the ground that it is some other form viewed in perspective, or is no proper cloud, but a mist or hoar frost. The following tables show the comparison of the two classifications:

NOMENCLATURE OF HOWARD.

First type.....	Cirrus.
Derivatives.....	{ Cirro-stratus.
	{ Cirro-cumulus.
Second type.....	Cumulus.
Derivative.....	Cumulo-stratus.
Third type.....	Stratus.
Derived from other types.....	Nimbus.

NEW NOMENCLATURE OF POËY.

First type.....	Cirrus.	
Derivatives.....	{ Cirro-stratus.	} Snow clouds.
	{ Cirro-cumulus.	
	{ Pallio-cirrus.	
Second type.....	Cumulus.	
Derivatives.....	{ Pallio-cumulus.	} Vapor clouds.
	{ Fracto-cumulus.	

Prof. Poëy's principal reasons for making this classification are stated by himself as follows: "When certain clouds spread out uniformly over the whole face of the heavens and assume a gray or ash color, under which state rain may occur for hours or whole days, what name do we give them? They are not Howard's nimbus, as we conceive them and as they are generally described; they are neither stormy nor electrical; they yield only a fine and continuous rain. Under this stratum we see constantly other clouds of more or less extent, but always isolated, becoming lost in it and increasing its thickness. But just before this stratum begins to break up, and during this operation, we see these same formless fragments detach themselves and fly to other regions. This inferior stratum is not alone; for when its disruption is completed we see through it another stratum of clouds, whiter and less dense, which breaks up in its turn, and ends by disappearing in an opposite direction to that of the inferior stratum. Have we a name for this variety of cloud, so common in time of rain from the intertropical regions to higher latitudes, especially in winter during the fall of snow? Does Howard's term nimbus and his description of it answer for its designation? Certainly not. We apply the name nimbus to the single storm cloud as well as to this inferior stratum, or to the united strata, and this without electrical manifestations. To this cloud I give the name of pallium. When the superior stratum is formed of cirrus, it constitutes the pallio-cirrus; and when the inferior stratum is formed of cumulus, it constitutes the pallio-cumulus. The fragments of clouds which differ entirely from the cumulus or cumulo-

stratus are the fracto-cumulus." Whether Prof. Poëy's classification is well founded time will decide. The propriety of rejecting the third class or type of Howard, the stratus, is rather questionable in the light of the opinions held by Prof. Loomis, some of which have been quoted, and also when we take into consideration the use Prof. Poëy himself makes of the word stratum in the explanation of his theory. The name fracto-cumulus appears to be applicable to some forms of cloud not otherwise clearly denominated, such as we often see at sunset; but the placing of the gray vapor cloud, which Prof. Poëy calls pallium, in the third division, stratus, by Prof. Loomis, would seem to supply the deficiency in Howard's classification with as near an approach to accuracy as the subject is perhaps capable of admitting.—An interesting feature in the phenomena of clouds is their gathering in the equatorial regions in a vast belt, which encircles the globe, and continues permanent and of nearly uniform breadth. This belt covers the region of equatorial calms, or the "doldrums," and vibrates with this, as the seasons change, from one side of the equator to the other, its range being from lat. 5° S. to lat. 15° N. It has been observed of various widths, ranging from 60 to several hundred miles. The cloud belt is produced by the vapors gathered up and brought in by the N. E. and S. E. trade winds from each side of the equator, and diverted in the belt of calms, where they meet, into the upper regions of the atmosphere. There, continually fed by new supplies from below of heated air saturated with moisture, the cloud spreads in one vast body over several degrees of latitude, passing even beyond the margin of the calms, seeing that its rains stretch out on each side into the region of the trade winds. Borne upward into the cooler strata of the atmosphere, the heated airs shed their moisture, which falls in frequent torrents of rain. But immense volumes of vapor upon the upper surface of the cloud, exposed in the heat of the day to the direct rays of the sun, are retained in an invisible state, and thus are wafted away to reappear as clouds, and precipitate their waters upon distant portions of the earth. This cloud belt serves another important purpose in protecting the torrid region it overshadows from the scorching heat of the sun; which, if continued without interruption, would in one season render the equatorial belt a barren, uninhabitable waste. It is the N. and S. vibration of the cloud ring that causes the fluctuations of the rainy seasons on the parallels of latitude within its range. When it has swung near to its extreme polar limit, the sky about the equator is clear, and the crust of the earth then begins to grow hot. "The dry season continues, the sun is vertical, and finally the earth becomes parched and dry; the heat accumulates faster than the air can carry it away; the plants begin to wither and the animals to perish. Then comes the mitigating

cloud ring. The burning rays of the sun are intercepted by it. The place for the absorption and reflection, and the delivery to the atmosphere of the solar heat, is changed; it is transferred from the upper surface of the earth to the upper surface of the clouds." Clouds are thus not merely the gatherers and distributors of rain to all parts of the earth, but they are a curtain spread before the sun to intercept its fierce heat, and check at night the too rapid evaporation from the soil heated during the day by its rays. Where they are not formed, and the surface is exposed to the sun, there we infer that water cannot be present, and the ground must be a parched desert. Such appears to be the condition of the side of the moon presented to the earth, no clouds ever being seen to obscure its disk. It has been shown by Tyndall that invisible vapor also has the power of absorbing radiant heat, and thus, by intercepting the fierce rays of the sun during the day, or the radiation of heat from the earth at night, of preventing, in atmospheres supplied with moisture, those great changes in temperature which take place in arid tropical regions. (See "Contributions to Molecular Physics in the Domain of Radiant Heat," New York, 1873.)—Little is known of the causes that produce the brilliant and varied colors often assumed by the sky, particularly at sunset. They are unquestionably, however, connected with the aqueous vapor contained in the atmosphere; and the reddish hue, the most common of all, is probably owing to the greater facility with which these rays are transmitted through the watery vesicles. Reflected from the surface of distant hills, they even give to these a delicate roseate hue.—The electricity of the clouds is a subject for more especial reference in the articles ELECTRICITY and LIGHTNING. Aqueous vapor being a better conductor of electricity than the dry air, the heavy clouds gather this force from the atmosphere around, some strata being positively and some negatively electrified. When separated by comparatively dry atmosphere, these clouds, or the clouds and the earth, are in the condition of a Leyden jar, ready to be discharged with sudden report when the non-conductor which separates them is broken through. As the clouds thicken and the watery particles more nearly approach each other, the electricity contained in the whole cloud gathers upon its surface, and at last acquiring sufficient tension to break through the non-conducting medium, the electrical equilibrium is established with the flash of lightning and the roar of thunder. The electrical condition of the clouds has been referred to as the cause of their being often gathered around the summits and sides of mountains, as if they were attracted to these, as light floating substances when electrified rush toward bodies in their vicinity. But the phenomena explained in the early part of this article show that the low temperature prevailing in these localities is sufficient to account

for the continual formation of a cloud, causing it to appear permanent, when it is but a process of condensation of new vapors brought on by the winds replacing those which are swept away and rendered invisible, as they dissolve in the warmer airs at a distance.

CLOUGH, Arthur Hugh, an English author, born in Liverpool, Jan. 1, 1819, died in Florence, Italy, Nov. 13, 1861. He was educated at Rugby school, and at Balliol and Oriel colleges, Oxford. In 1842 he gained a fellowship at Oriel, which he resigned in 1848, because his theological opinions did not accord with those of the established church. In 1848-'9 he travelled on the continent. He was in Rome, where he was intimate with the leading Italian liberals, during the siege of that city by the French. Upon his return to England he was made principal of University hall, and professor of the English language and literature in University college, London. In 1852 he resigned this appointment, came to America, settled at Cambridge, Mass., and engaged in teaching and literary pursuits. The next year he returned to England to accept a position under the committee on education. After the close of the Crimean war he was appointed secretary to a commission to examine the military systems of the continent. At the time of his death he was travelling for the benefit of his health. His chief work, a poem in hexameters entitled "The Bothie of Tober-na-Vnolich," was published in 1848. In 1858 the "Amours de Voyage," a story in verse, appeared in the "Atlantic Monthly." He revised Dryden's translation of "Putarch's Lives" (Boston, 1859), and just before his death wrote "Mari Magno," a series of tales. A collection of his poems, with a memoir by Charles Eliot Norton, appeared in Boston in 1862.

CLOVER (*trifolium*), a genus of plants belonging to the natural order *leguminosæ*, comprising 59 species, and generically distinguished as tufted or diffuse herbs, with flowers in heads or spikes, leaves mostly palmately trifoliate, a persistent 5-cleft calyx, the standard of the corolla longer than the wings, small 1-6-seeded pods, and stipules joined with the petioles. From the three leaflets which constitute its leaf it takes the name *τρίφυλλον* in Greek, *trifolium* in Latin, and trefoil in English.—There are several of the many varieties of clover of great value to agriculturists. Red clover (*T. pratense*) is a biennial plant, having perennial qualities under special modes of cultivation, and is particularly adapted to argillaceous soils. Small clover, or the rowen crop, is excellent for young stock; but animals should not be permitted to feed on clover lands in early spring or late in the autumn; in the latter case the crop is likely to be winter-killed for want of a mulch-like protection, and in the former is not able to regain full vigor during the after part of the season, and this is especially true if sheep are the pasturing stock. Land may be seeded down to clover with any of the cereal

crops, such as wheat, barley, rye, oats, and in special cases with buckwheat. It is very desirable that the seed should be sown sufficiently early to receive the full benefit of the spring rains. The dung of cattle fed on clover hay is often sufficient to seed land, if distributed evenly through the soil, the seed generally passing through the animal organism without having its germinating qualities impaired. The proportion of seed to be sown with timothy or

Red Clover (*Trifolium pratense*). a. Pod. b. Seed.

other grass seeds must necessarily vary with the results desired. In order to secure even distribution, it should be sown in calm weather. Standing on one ridge while sowing on another, as is sometimes done, on a windy day, is unfavorable to good work. In dry weather, and on clayey soil, it is well to bush-harrow in order to insure full covering, and occasional rolling is very desirable. Every farmer should have plenty of clover for soiling in early spring for his working animals. After each cutting during the season, top-dress heavily with manures. Land becomes "clover sick" only in the absence of a proper succession of crops, and the elements of fertility necessary for the support of the plant. Many farmers have great faith in the power of clover, when ploughed in, to restore fertility to exhausted soils. It does so only by taking carbon from the atmosphere, and causing elements in the soil to assume organic forms, thus rendering them more available as food for other crops, and is therefore very necessary in a rational system of husbandry; but if a soil be almost robbed of its fertility by excessive cropping, its equilibrium must be restored by adding deficient elements. Land is often too poor for the seed "to take." In this case it should be summer-fallowed, manured, sowed to winter grain, and to clover in the spring. Prof. Way found in 100 parts of the ash of clover, grown on a silicious sand, phosphoric acid 5.82, lime 35.02, potash 18.44, soda 2.79, sulphuric acid 3.91. As indicated by

analytic research, plaster of Paris, which is sulphate of lime, the phosphates, wood ashes, and muck treated with the salt and lime mixture, are excellent top-dressings for clover. The use of plaster, sometimes called gypsum, is often of great value for top-dressing, even in the immediate vicinity of plaster beds. The practice of ploughing in a clover crop preparatory to the growing of wheat is of much importance. There is a great similarity between the composition of the ashes of wheat and clover, especially if the latter be grown on soil replete with the necessary constituents. Analytical research has shown that the composition of clover or any other plant varies with the chemical condition of a soil. Clover crops should therefore be raised on soils containing sufficient pabulum, and in an available condition for their support. The growing of clover is equal to deep ploughing, because its long roots travel deeply in search of food for the stems and leaves, which if ploughed into the land will undergo decomposition, and leave near the surface elements taken from the subsoil. Its leaves take carbonic acid largely from the atmosphere, and the ploughing in of the crop augments the carbon of a soil very materially, which changes its color, and gives it greater capacity to absorb solar heat and to retain manures and ammonia, whether resulting from their decomposition or absorbed from the atmosphere. It is very doubtful whether in all cases clover is the most economical mode of furnishing carbon. If time be worth much, it is not, because an immediate application in most cases may be made of muck treated with the salt and lime mixture, black mould from the woods, peat, river deposits, &c.—Clover fields are sometimes infested by vegetable parasites of well developed structure, producing seed. The small broom (*orobanche minor*) is one of these. Its flowers are of a pale brownish color. Microscopic examinations show that when it infests clover there is an organic connection between the plants. This parasite is interesting to the agriculturist, not for its utility but for its mischief. The dodder (*cuscuta*) is another of these depredators, belonging to the family of the *convolvulaceae*, having small flowers resembling those of the convolvulus. It bears perfect seed, which is shed upon the soil, and there germinates, pervading the ground by a wire-like process, doomed to a lingering death unless it finds a clover plant. In the commencement of its growth it gets its nourishment from the soil, but afterward from the juices of the plant which it infests. The dodder will find the object of its destruction if within reach, and its papillæ or peg-like processes, although delicate in structure, will sink into the stalk and feed upon the juices of the clover plant.—The crimson clover (*T. incarnatum*) is now raised for soiling and hay, and is a beautiful Italian plant, sometimes cultivated as a border flower. Much attention is given to its cultivation at present in Scotland.

Fulton's experiments in growing crimson clover attracted special attention from the members of the Highland agricultural society. A large crop was raised from seed sown by Mr. Fulton on land from which a crop of early potatoes had just been taken. Three months after it was sown, on Oct. 17, the yield was 2½ tons per imperial acre. He arrived at the following conclusions: It is highly valuable as a secondary crop after early potatoes; it is an excellent intermediate crop to precede turnips; it will withstand severe weather if well established before frost; it produces an excellent crop of forage, much relished by live stock. If the land is not very clean, it will not answer so well as vetches, but it is of easy cultivation. Maturing 10 or 12 weeks after sowing, it may be produced very early in the season if wanted for stock.—White clover (*T. repens*) is an excellent plant on all pasture lands, of great value in sheep husbandry, adapted to almost every kind of soil, and its network of roots is

White Clover (*Trifolium repens*).

all through the soil.—The following analyses of red and white clovers are by Prof. Way of the royal agricultural society of England:

	Red Clover.	White Clover.
Water.....	81.01	79.71
Albuminous or flesh-forming principles.....	4.27	3.80
Fatty matters.....	.69	.89
Heat-producing principles—starch, gum, sugar, &c.....	8.45	8.14
Woody fibre.....	3.76	5.33
Mineral matter or ash.....	1.82	2.08
	100.00	100.00

One hundred parts of each of the varieties named, dried at 212° F., gave the following results:

	Red Clover.	White Clover.
Albuminous or flesh-forming principles.....	22.55	18.76
Fatty matters.....	3.67	4.38
Heat-producing principles—starch, sugar, gum, &c.....	44.47	40.04
Woody fibre.....	19.75	26.53
Mineral matter or ash.....	9.56	10.29
	100.00	100.00

These researches of Prof. Way are most valuable contributions to the science and art of agriculture. Boussingault found the nutritive equivalent of red clover hay, taking English hay as the standard, to be as 79 is to 100; the difference of result obtained by Fresenius in a like experiment need only be looked at. Thaeer, a most careful experimenter, found its practical value in feeding to bear the same relation to English hay as 90 to 100. He found the nutritive equivalent of red clover in the green state to be as 311 to 100, and its practical value in feeding to be 450 to 100.—If clover for hay is left till very ripe without cutting, the starch and sugar of the plant will change to woody fibre, thus causing brittleness if much exposed, and rendering the hay almost valueless. The nectaries of clover heads, when fully developed, are rich in a honey-like liquid, hunted for by bees, and if the crop is mown before the seed ripens this saccharine property will be preserved. In growing seed, it is common to pasture the first year's growth, or cut a crop of hay, and leave the second growth for seed; but if the cutting is not done early, the frost may check its growth, thus preventing its maturity. After threshing, it is run through a hulling machine, and then a fanning mill. Clover is much more succulent than any of the grasses usually raised for hay, requiring more time to part with its moisture, and should be cut only when free from dew. If dried by a hot sun, it heats in the sward, wilts, becomes dark-colored, and loses flavor and aroma. It should be saved in the cock, and only so much mown at one time as can easily be brought under cover if rain threatens. Make no hand or rake rolls; use forks; any unnecessary compression breaks the structure of the plant, and makes the sap exude. The usual application of salt at the time of putting it in the mow is beneficial. In special cases the mixing of clover hay with straw or other fodder of the previous season is desirable, especially if it be not thoroughly dried. Green clover hay imparts flavor, aroma, and freshness to old fodder, thus causing animals to relish the mixture.

CLOVES, a celebrated spice of the Molucca islands, so called from the resemblance to small nails, and designated in all countries wherever known and used by a term having this signification (Port. *cravos*, Span. *clavos*, from Lat. *clavus*, a nail). The clove of commerce is the product of the largest and most elegant of the myrtle family, the *caryophyllus aromaticus* of Linnæus, and is described by Rumpf, in his *Hortus Amboynensis*, as "the most beautiful, the most elegant, and the most precious of all known trees." In its native soil, which is confined to the islets Ternate, Tidor, Mortir, Makian, and Batshian, on the west of Gilolo, the true and original Moluccas, this tree grows to a height of 40 ft., begins to bear the spice blooms in its seventh year, and attains to an age varying between 100 and 200 years. The trunk is perfectly straight, the bark smooth and of a light

olive color; about half the height the branches spring out horizontally and thickly, diminishing in length as they ascend, so that the compact mass of foliage, composed of slender laurel-shaped leaves, forms a perfect cone, supported by a clean straight stem. The spice is not the fruit, as is very commonly supposed, but the blossom, which is gathered before it is quite unfolded, when it resembles a closed-up convolvulus bloom. About a dozen of these blooms form a terminal cluster at the extremity of each twig and branch of the tree. The stem of the spice is the calyx, and the head the unblown corolla of these aromatic flower buds. The best season for collection in the Moluccas is in December; they are gathered quickly and carefully, and speedily dried in the shade before they have an opportunity to exhale the strength of their aroma.—When the Portuguese and Spaniards first visited the Moluccas, and when Magalhaens's ship, the Victo-

Clove.

ria, took on board at Tidor, in 1521, the first cargo of spices that was brought to Europe, the Molucca islands were cultivated by a numerous, enterprising, and industrious population, for the almost exclusive production of their great staple. Malacca was the chief emporium of the trade in cloves, from whence they were carried by various transits to every part of the then civilized world. The Portuguese held the spice islands for 93 years, restricting the culture, and preventing the free exportation of the article. When the Dutch drove the Portuguese from the Moluccas in the beginning of the 17th century, they established the clove culture in Amboyna, where it had been partially introduced by the natives prior to the Portuguese conquest. Then commenced the process of extirpation of every clove tree that grew upon the islands which were their natural home. Every year an expedition was sent to Ternate, Tidor, Mortir, Makian, and Batschian, to cut down every clove bush which

migratory birds might chance to plant in the native soil; and every native was punished with death who was known to plant a clove tree or sell one pound of its spice blossoms. When the forests were destroyed, the fertile volcanic soil was washed away by tropic rains and burned up by a tropic sun; the land became barren, and the people, who had lost their trade and their subsistence, perished of starvation at home, or as slaves in the plantations of Amboyna. Not only were the clove trees of the other Molucca islands destroyed, but also a large portion of the product of Amboyna was annually burned, in order to enhance the value of what remained in the hands of the monopolists. These annual burnings were continued till 1824. The clove tree in Amboyna falls far short in duration and productiveness when compared with the tree in its native region. In Amboyna it does not begin to bear spice till its 15th year, and its duration is not more than 70 years. It is raised still less advantageously at other points where its culture has been introduced, at Bencoolen in Sumatra, in the Straits settlements, at Zanzibar, and in the French islands of Réunion (formerly Bourbon) and Cayenne. The three varieties mentioned in commerce are those of Amboyna, Bourbon, and Cayenne. The clove thus far has defied all efforts, skill, and care to rear it in the same perfection to which it attains in its native soil. It requires tropic heat, a mountain declivity, with loose, dry, volcanic soil, and a frequent overshadowing of vapory clouds; all of which circumstances are only found combined in the Moluccas.—Cloves are sometimes used in substance as a stimulant to the digestive organs, but the oil is usually employed, chiefly as a corrigent to medicines. It may be used, in the same way as creosote or carbolic acid, to relieve the pain of a carious tooth. Oil of cloves is useful in microscopy for rendering transparent thin sections of tissues which have been soaked in alcohol. Nitric acid gives with oil of cloves a deep red color, similar to that produced by the action of the same reagent on morphia. In the latter case, however, but not in the former, the red is followed by a yellow. A tablespoonful of the infusion of cloves, given every hour or two, will sometimes relieve the vomiting of pregnancy; but it should not be administered if any inflammation of the stomach is present. The pungent sensation in the mouth produced by chewing cloves is strong enough to obliterate momentarily the taste. Advantage may be taken of this action in the administration of disagreeable medicine. For instance, the taste of cod liver oil will not be recognized if swallowed directly after chewing cloves.

CLOVIS, the founder of the Frankish monarchy, born at Tournai about 465, died in Paris in 511. On the death of his father Childeric (481), Clovis, then about 15 years old, was proclaimed king by the Salian tribe, then established around Tournai. Their territory was

small, and the Salian warriors were few in number; nevertheless within 30 years Clovis had secured for himself a powerful empire. On his accession Rome had been for five years in the hands of Odoacer, who had overturned the imperial throne; but the central part of Gaul was still governed by a Roman officer, named Syagrius, who was conquered by Clovis in the vicinity of Soissons (486), and fled to the Visigothic court at Toulouse; but upon the menaces of Clovis he was given up, and afterward put to death. The whole Belgic country, the cities of Soissons, Rheims, Troyes, Beauvais, and Amiens, submitted to the victor, who rapidly extended his dominion from the Scheldt to the Loire. He thus became one of the most powerful princes in Gaul, and was courted by the Catholic bishops of that country, who saw in him the future supporter of their faith, and succeeded in giving him as a wife Clotilda, the only Catholic princess in Gaul. At first she found him reluctant to renounce the worship of his national god, and it is narrated that a miracle was required to overcome his resistance to Christianity. The Alemanni had crossed the Rhine, and, following in the footsteps of the Franks, intended to settle in the rich plains of Gaul. Clovis hastened to repel them, and in a battle near Tolbiac (496) they were already raising the shout of victory, when Clovis in despair thought of the God of his wife, and throwing himself on his knees, exclaimed: "God of Clotilda, give me assistance in this hour of necessity, and I confess thy name." The course of victory was immediately turned; the Alemanni fled, while the flower of their forces and their king were killed. Within the same year Clovis, true to his vow, was baptized at Rheims by Bishop Remy, and with him 3,000 of his companions. In a short time this example was followed by the greater part of the nation. Henceforth Clovis became popular among the Catholics in Gaul, all the bishops of that communion, impelled by their opposition to the Arians, representing him as the deliverer of the faithful. Yielding to the entreaties of his wife (see CLOTILDA), Clovis invaded Burgundy, conquered Gundebald near Langres, and took several important cities, but finally contented himself with laying a tribute on the Burgundian kingdom. In 507, having summoned his warriors to the banks of the Loire, he thus addressed them: "I am displeased with those Arians possessing that beautiful country of Aquitania; let us go there and take it at once, for the land is very good." He then crossed the Loire and fell upon the Gothic army near Poitiers. The Visigoths were routed, their king Alaric was slain, and the greater part of Aquitania submitted to Clovis. Theodoric, the king of the Ostrogoths, however, succeeded in retaining Septimania. Clovis was then the sovereign of the whole country from the lower Rhine to the Pyrenees, bounded E. by the Vosges and the Cévennes, with the exception of several small districts

in the north still belonging to Frankish princes of his own family, some of whom had assisted him in his wars. But by the most treacherous and cruel means he got rid of these petty rivals, and became the only monarch of his race. He died soon afterward, and was buried in the basilica of the Holy Apostles, which had been built by him and Clotilda. He left four sons, among whom he had divided his dominions. Theodoric, the eldest, born to him by a first wife or mistress, probably of German descent, obtained the eastern country bounded by the Rhine and the Meuse, with the western part of Germany and some provinces in Aquitania; Childebert, Clodomir, and Clotaire, sons of Clotilda, were kings at Paris, Orleans, and Soissons, the last finally uniting under his power the dominions of his brothers.—Two other Merovingian princes of the same name, Clovis II. and Clovis III., lived in the 7th century; but they were mere tools in the hands of powerful mayors of the palace, and belong to that succession of Frankish kings known as the *rois fainéants*.

CLOWES, John, an English clergyman, born at Manchester, Oct. 31, 1743, died at Leamington, May 29, 1831. He was a fellow of Trinity college, Cambridge, and in 1769 was made rector of St. John's church, Manchester. Having become in 1773 one of the first English disciples of Swedenborg, he was thenceforward earnest in promoting his doctrines, although he retained his rectorship for nearly 60 years. He translated Swedenborg's *Arcana Cælestia* and other works, and published "Restoration of Pure Religion," two volumes of sermons, &c.

CLOWES, William, an English printer, born at Chichester, Jan. 1, 1779, died Jan. 26, 1847. His father was a schoolmaster, who died leaving his family in straitened circumstances. The son, after receiving a fair education, was apprenticed to a printer in his native town. In 1802 he went to London, worked for a year as a compositor, and then commenced business on his own account in a small way. Having married the cousin of a stationer who had much government business, he soon obtained considerable official work, and in a few years found himself at the head of a large printing establishment. In 1823 he commenced the use of steam presses, and the process, being a new one, excited much attention. In a few years his establishment grew into the largest printing office then existing, comprising 24 steam presses and 28 hand presses, and employing 600 persons. Upon the establishment of the "Penny Magazine," and subsequently of the "Penny Cyclopædia," he undertook the printing and publication of them, which he executed for 14 years with unvarying promptness, meanwhile extending his operations as a printer in other directions. He was among the first printers to have fonts of type so large that an entire work could be set up without distributing the type, so that in case of need he could execute 1,000 pages a week, or keep

a whole volume standing to await the author's final revision, thus often having tons of type standing out of use. The establishment which he founded is still among the largest in England, printing much for the great publishers.

CLOYNE, a market town of Ireland, in the county and 15 m. S. E. of Cork; pop. in 1871, 1,434. The cathedral, built in the 13th century, contains monuments of Bishops Warburton and Woodward, and near it is a remarkable round tower, more than 90 ft. high. The bishopric is said to have been founded in the 7th century by St. Colman, and the abbey in 707. In the 15th century the see was united with that of Cork, but it became independent again in 1678. Among the celebrated bishops of Cloyne were Berkeley and the astronomer Brinkley, who died in 1835, when the see was reunited with that of Cork. There are valuable quarries in the vicinity.

CLUB, a word of Saxon derivation, signifying a society of persons united for political, social, scientific, artistic, or literary ends, or for purposes of recreation. Clubs differ from mere associations in having some social bond, such as a place of meeting where the members associate in friendly personal intercourse. The modern English club differs considerably from those of two centuries since, which last better answered Johnson's definition of "an assembly of good fellows, meeting under certain conditions." Such was Ben Jonson's club at the "Devil Tavern." Political clubs came into existence at a later period. The King's Head club was a famous political association during the reign of Charles II. Clubs became numerous in England in the early part of the 18th century. The Brothers' club, of which Bolingbroke, Harley, and Swift were members; the Hanoverian club; the Beefsteak club, presided over by Peg Woffington, the actress; and the Kit-cat club, flourished in this era. In 1735 was established the second Beefsteak club, which has embraced among its members the most eminent public men. The Literary club, established in 1764, by Johnson, Boswell, Reynolds, Goldsmith, Burke, and others, is still flourishing. The club of the Friends of the People was established in London in 1793, for political purposes, by Lord Grey. From England the designation "political clubs" spread to similar organizations in France and other countries. They were prohibited in Germany in 1793. In France they were the focus of the revolution. The first French society that took the name of club was the *club politique*, established at Paris in 1782; a second was organized in 1785 under the name of the *club de Boston* or *des Américains*; and afterward the appellation of club was adopted by most political societies. The most celebrated clubs of the revolutionary period were the *clubs des Jacobins*, *des Feuillants*, *des Bretons*, *des Cordeliers*, *de Montrouge*, and *des enragés*. Clubs for social, literary, artistic, and political purposes are now found in every large city in the civilized world.

CLUB-FOOT, a deformity arising from rigidity and contraction of the muscles of the leg, in which the individual walks, with one or both legs, on the toes, on the external or internal border of the foot, or in some rare forms on the heel or the top of the foot. This deformity, which may be congenital or accidental, was known to Hippocrates; Celsus gave the names *varus* and *valgus*, which are still used, to two of the varieties; but the true anatomical history of the affection may be dated from 1803, when Scarpa published his memoir on the subject. In the simplest form, called *talipes equinus*, the heel is so raised that the person walks on the ball of the foot; this may vary from an elevation of an inch or two to a perfect continuation of the axis of the leg with that of the foot; it may be complicated with distortion inward or outward, and, in old cases, with permanent flexion of the leg on the thigh from contraction of the hamstring muscles. In *talipes varus*, which is the most common, the distortion is more complex; the heel is raised, the inner edge of the foot is drawn upward, and the whole foot is twisted inward, so that the person walks on the outer edge, and in extreme cases on the top of the foot and the outer ankle. In this form the limb is small, the muscles of the calf being feebly developed; the toes arranged vertically, the great toe uppermost; the sole of the foot very concave, and the back very convex; the external ankle turned backward, and very near the ground, the internal high up and approaching the heel bone; a callus on the outer edge which corresponds to the sole. Walking is difficult and fatiguing, and the standing position insecure; when existing in both limbs, the feet must be constantly crossed over each other in walking; from the inward rotation of the limb the knee is turned outward, which increases the difficulty of standing and walking firmly. The joints are generally movable; the tendo Achillis is tense, shortened, and turned inward with the heel. In new-born children the foot can be brought into the natural position, and in them *varus* is almost always combined with some degree of the first variety; indeed, the two are usually combined, giving a great number of intermediate forms. In *talipes valgus* the characters are the opposite of *varus*; the outer edge of the foot is raised up, and the person walks on the inner ankle and metatarsal bone of the great toe; the foot is strongly turned outward, as is the heel; the internal border is convex and the external concave; in this variety walking and standing are still more difficult and fatiguing. An extreme degree of *varus* has been described by Duval, in which the dorsum or back of the foot touches the ground; in its first stage the foot rests on the dorsal surface of the great toe, the other toes being rolled inward toward the sole; in the second, the deviation begins further back, and the metatarsus is bent at a right angle toward the sole; and in the worst form the whole anterior part of the foot is turned back, the dorsum

resting on the ground and the sole turned upward. This is usually congenital, and accompanied by deformity and stiffness in the other joints of the limbs, and depends on contraction of the flexors of the toes and the muscles of the calf. A fifth form is described, in which the toes are turned upward, the dorsum of the foot approaching the anterior surface of the leg, and the person walking on the heel. Club-foot consists essentially in a contraction, rigidity, and atrophy of the muscles of the calf, the deformity taking place in whichever direction the muscular equilibrium is the most easily disturbed.—Various causes have been assigned for congenital club-foot, such as vicious positions of the foetus, and mental and physical affections of the maternal system, such as are generally supposed to cause arrests of development. Convulsive diseases in infancy often cause permanent contraction of the muscles and consequent club-foot. Before the time of Scarpa it was supposed that there was in club-foot a dislocation of the bones of the tarsus and metatarsus; he maintained that there was rather a torsion of the scaphoid, cuboid, and os calcis, which would carry with them in the same direction the rest of the foot. The deformity may depend on an abnormal conformation of the astragalus and cuboid bones, with deviation of the anterior bones, this being especially the case in congenital club-foot; and in some rare forms there may be dislocation of the astragalus, though in most cases this bone preserves its normal relations to the tibio-tarsal articulation. In *varus*, the scaphoid and cuboid and heel bones are rotated outward, and the ligaments which bind the last two are generally relaxed; in congenital cases all the bones are small and the muscles wasted, and the limb is cold and feeble, indicating imperfect nutrition and innervation; the tibialis anticus and posticus, the flexors of the toes, and the muscles of the calf, being stronger than the peroneal muscles, increase the torsion as age advances, and the tense tendo Achillis draws the tuberosity of the os calcis obliquely upward. In *talipes equinus* the astragalus is more or less dislocated forward, and may be felt under the skin at the top of the instep; when the foot is rolled backward, the bones of the tarsus are more or less separated on their dorsal surface, and the joints below are proportionally approximated; the dorsal ligaments are thin and elongated, while those of the sole are shortened and thickened. In *valgus*, the deviations of the tarsal bones are the opposites of those in *varus*.—In children the prognosis is more favorable than in adults, on account of the flexibility of the muscles and the suppleness of the joints. Until the latter part of the last century the only means employed for the treatment of club-foot were various kinds of bandages and apparatus for extension; these were inconvenient, painful, expensive, requiring years of trial, and useless except in the simplest cases and in early childhood. The indications for

treating club-foot are fulfilled by the division of the tendo Achillis, or any other contracted tendon or tense fascia, and an apparatus for extending the foot at right angles with the leg. The tendo Achillis had been for many years frequently divided in veterinary practice, but was not interfered with in man for the cure of club-foot until about the year 1782; though an acknowledged operation in surgery, it was not practised in France until 1816, when Delpech performed it with indifferent success; it had become almost forgotten when Stromeyer revived it in 1831; since that time the operation has become improved and simplified, and the apparatus for extension rendered efficient by Duval, Bouvier, Guérin, Roux, and the best surgeons of Europe and America. Tenotomy, as the operation is called, has been performed at all ages, from a few weeks to 50 years, and has been applied not only to the tendo Achillis, but to the flexors of the toes, the plantar fascia, and any of the tendons surrounding the ankle joint which seem to aid in producing the deformity. The operation is so simple, so free from pain, so easily performed, so little liable to unfavorable consequences, and generally so speedily efficacious, that it seems unpardonable, unless in a few exceptional cases, for a surgeon to submit his patient to the plaster moulds, starched bandages, and other immovable apparatus of the old method. The divided tendon heals by a callus, which, when recent, may be extended to any desired length; the wasted antagonist muscles, being relieved from tension, gradually recover their power. At first the knife was passed under the tendon, piercing the skin largely on both sides of the limb, and extension was not applied until the fifth week, when the divided ends had contracted adhesions and lessened the chance of a favorable result. Stromeyer improved upon this by making a single puncture of small size, and by putting on the apparatus in the course of the second week. The tenotome is generally blunt-pointed, the skin being pierced by a lancet; it is introduced on the inner side of the limb, and is made to cut the tendon, previously put upon the stretch, from before backward, or toward the skin, without wounding the latter; this subcutaneous operation is painless, bloodless, and, from the exclusion of air from the wound, not liable to be followed by inflammation; extension should be applied as soon as it can be done, without causing too much pain.

CLUNY, or **Clugny**, a town of France, in the department of Saône-et-Loire, 12 m. N. W. of Mâcon; pop. in 1866, 4,253. It has several churches and schools, manufactures, a government stud, and some trade in cattle, horses, timber, and grain. The town sprang up around a Benedictine abbey, founded in the 10th century, which in the 11th and 12th centuries acquired great celebrity. Popes Gregory VII., Urban II., and Pascal II. had all been inmates of this abbey, which was inhabited at one time by

10,000 monks, and controlled over 600 religious houses. The most illustrious of the abbots was Pierre Maurice, or Pierre de Montboissier, known as Peter the Venerable, who gave an asylum to Abélard, and after his death befriended Héloïse. Subsequently the abbey declined, and in 1562 it was partly ruined by the Huguenots. In 1789 the monks were expelled, and in 1792 their famous basilica, once the finest church connected with a monastery, was plundered by revolutionary troops, and the building itself was sold at auction and pulled down. Only two towers of it remain, with fragments of the south transept, the Bourbon chapel, and some walls. Its library was one of the most renowned in France. A normal school for training special teachers for lyceums and colleges was established in 1865 in the remaining parts of the ancient abbey. The annual prizes and medals are awarded in a grove which is said to have been planted by Abélard. —The Cluny museum of national antiquities (*musée de l'hôtel de Cluny*) in Paris derives its name from one of the abbots of Cluny, who in the 14th century built the palace of Cluny for the use of his order; but the abbots did not often reside there, and gave the use of it to princes and cardinals. In 1790 it was confiscated and sold. The city of Paris purchased it in 1842, and presented it to the government, together with the ruins of a Roman palace belonging to it and called Thermes de Julien.

CLUSERET, Gustave Paul, a French soldier, born in Paris, June 13, 1823. In 1841 he entered the military school of St. Cyr, and two years afterward was appointed sub-lieutenant. In April, 1848, he was made a major in the *garde mobile*, and took part in suppressing the insurrection of June. In 1849 he was retired on half pay, and opened a painter's studio. In 1851 he reentered the army as lieutenant in the *chasseurs à pied* of Algeria. In the Crimea (1855) he was wounded and promoted to a captaincy. In 1856 he joined the expedition against the Kabyles, and was named chevalier of the legion of honor. He resigned his commission in 1858, and in 1860 became attached to the staff of Garibaldi, was placed in command of the French legion, and in November received the brevet rank of colonel. In 1862 he came to America, entered the Union service, was attached to the staff of Gen. McClellan, and afterward served under Fremont in Virginia. In October, 1862, he was made brigadier general of volunteers. After some further service in the valley of the Shenandoah, he retired from the army, and in 1864 edited the "New Nation," a weekly journal in New York, which advocated Fremont for president and vehemently opposed the renomination of Lincoln. He returned to France in 1867, but was expelled in 1869 for publications against the transcontinental railway project in the United States, in which some prominent French officials were interested. He was subsequently for some time in New York, but re-

turned to Europe during the Franco-German war in 1870. In Paris he affiliated himself with the assailants of the government of national defence, but soon after left the capital and engaged in insurrectionary attempts in Lyons and Marseilles, which proved abortive. In the following spring he became minister of war in Paris under the commune, and for a short time was at the head of military operations, but fell under suspicion of treachery to the cause and was for a time confined in the Mazas prison. After the downfall of the commune he succeeded in escaping to Switzerland. Sentence of death was passed against him in his absence in the summer of 1872. He has since resided near Geneva.

CLUSIUM (the modern *Chiusi*), one of the twelve cities of the ancient Etruscan confederation, situated on the right bank of the Clanis, near a small lake to which it gave name, and 83 m. N. N. W. of Rome. Virgil mentions it among the cities which assisted Æneas against Turnus. Its original name is said to have been Camars. Under the rule of Porsena, about 500 B. C., it espoused the cause of the Tarquins, and in conjunction with other Etruscan states laid siege to Rome, which is supposed by modern critics to have surrendered, and submitted to humiliating conditions of peace. But the final issue of the war seems to have been unfavorable to the Etruscans, though how or when is not certainly known. During the later wars of the Romans with the Etruscans we hear of the Clusians only once, and then in conjunction with the Perusians, who were enemies of Rome. At what time Clusium passed under the dominion of the Romans is unknown. In 295 B. C. a Roman legion stationed at Clusium was cut to pieces by the Gauls. The latter in their third great invasion, 225 B. C., appeared under the walls of Clusium shortly before their decisive defeat at Telamon. In the second Punic war Clusium was under Roman rule, and furnished Scipio with corn and timber for his fleet. In the civil wars of Sulla and Marius the Clusians sided with the partisans of Marius, who were twice defeated near the city. Under the empire Clusium seems to have received a fresh colony of citizens, who enjoyed separate rights, and are mentioned as *Clusii novi*, in distinction from the *Clusii veteres*. But few remains exist of the former greatness of the city. (See **CHRUSI**.)

CLUVERIUS, or **Cluver, Philipp**, a German geographer, born in Dantzic in 1580, died in Leyden in 1623. His father destined him for the law, but withdrew his support on his devoting himself at Leyden to the study of geography and history under the direction of Scaliger. He enlisted as a private in the imperial army, and was imprisoned in Bohemia for translating into Latin a paper which was obnoxious to the government. After his release, his mother secretly supplied him with money, and he resided some time in England, and travelled through Scotland, France, Ger-

many, and Italy. At Oxford he made the acquaintance of Drs. Holland and Prideaux, and the latter procured him offers of promotion. But he returned to Leyden, where the university gave him an annual stipend. His *Introductio in Universam Geographiam tam Veterem quam Novam* (Leyden, 1629; best ed., Amsterdam, 1729; translated into German, 1733), was regarded as the first attempt at a comprehensive system of geography. Among his other works are archaeological descriptions of Italy (edited by Daniel Heinsius, 2 vols., Leyden, 1623), of Sicily, Sardinia, and Corsica, (Leyden, 1619; and Wolfenbüttel, 1659), and *Germania Antiqua* (Leyden, 1616 and 1631).

CLYDE, the most important river of Scotland, rises in the southern part of Lanarkshire, out of the northern declivities of the chain of hills which may be regarded as a part of the Cheviots, dividing Lanarkshire, Peeblesshire, Selkirkshire, and Roxburghshire from Dumfriesshire. It runs principally in a N. W. direction, passing by Lanark, Hamilton, Bothwell, Rutherglen, Glasgow (which is the head of ship navigation), and Renfrew, and falls into the great estuary known as the frith of Clyde, formed by the concurrence of its own waters with those of Loch Long, coming down from the northward. This large river mouth, or arm of the sea, extends southward between the isles of Bute and Arran, which divide it on the west from Loch Fyne and Kilbrennan sound, and the shores of Renfrewshire and Ayrshire; off the latter it enters the Irish sea, between the mull of Cantyre and Kirkcolm point in Wigtonshire, nearly opposite Tor point, the extreme N. E. promontory of Ireland. The total length of the Clyde, from its source to the S. point of Bute island, is about 115 m. Its valley is one of the most interesting and the richest in old historic and legendary lore, as well as in agricultural and commercial wealth, of all the beautiful vales of Scotland. Its magnificent falls of Corra Linn and Stonebyres have been described by the most eloquent writers, and its banks are the scene of Scott's "Old Mortality." The valley of the Clyde is famous for a peculiar race of strong black cart horses, known as the Clydesdale breed. Commercially, the embouchure of the Clyde monopolizes the American, West Indian, and South American trade, besides attracting to itself a large portion of the Indian and Australian commerce. This is the more remarkable, since the Clyde is for the most part, as a navigable river, an artificial stream. Formerly a shallow, rapid river, obstructed by sand banks, it has been converted into a fine, uninterrupted, easily navigated avenue for ships of large burden, up to the splendid wharves of the great city which has grown up on its banks. The Forth and Clyde canal, which enters the latter river a little way below Kilpatrick, some 10 m. lower down the river than Glasgow, connects it with Borrowstounness on the Forth, about 30 m. above

Leith, and affords a perfect communication between the E. and W. coasts. It was commenced in 1777, and completed in 1790. Its total length is 35 m.; its greatest elevation, at its summit level, is 156 ft., which it reaches in 10½ m. by means of 20 locks, while on its descent to the western tide water, which it reaches at Bowling bay, it has 19 locks. When full, it can carry vessels drawing 8 ft. of water, and its locks have a length of 74 ft. and a width of 20. It was the earliest considerable Scottish work of the kind, and continues to be one of the most important, being the great connecting channel for the trade of the E. and W. coasts of the kingdom. There is also a branch to this canal, 2¼ m. in length, terminating directly in Glasgow.

CLYDE, Lord. See CAMPBELL, Sir COLIN.

CLYMER, George, a signer of the declaration of independence, born in Philadelphia in 1739, died at Morrisville, Bucks co., Pa., Jan. 23, 1813. Left an orphan at the age of 7 years, he was adopted by his uncle, William Coleman, who educated him, brought him up to mercantile pursuits, and eventually left him the bulk of his fortune. His first appearance in public life was at a "tea meeting" in Philadelphia, Oct. 16, 1773, when he was made chairman of the committee to request the tea agents to resign, and soon after he was a member of the council of safety. He was one of the first two continental treasurers, from July 29, 1775, to Aug. 6, 1776, when he resigned. During his term of office he converted all his own specie into continental money, besides subscribing liberally to the loan. On July 20, 1776, with four others, he was appointed to succeed the members of the Pennsylvania delegation who had refused their assent to the declaration of independence; and, although he was not present when it was agreed upon, he and his associates signed that instrument. He was appointed with Stockton, Sept. 26, 1776, to visit Ticonderoga and inspect the northern army. When congress removed in December to Baltimore, he was appointed one of the commissioners to guard the public interests in Philadelphia. He was reelected to congress, March 12, 1777. On July 11 he was appointed one of the commissioners to inspect Washington's army. After the battle of Brandywine, Sept. 11, the British plundered and burned his country residence in Chester co., 25 m. from Philadelphia. On Dec. 11 he was appointed one of the commissioners to treat with hostile Indians, and to endeavor to suppress disaffection among some of the whites on the western frontier of the states. From November, 1780, to November, 1782, he sat for the third time in the continental congress. In 1780 he was deputed with John Nixon to organize the bank of North America, and in 1782 he was associated with Rutledge in a mission to persuade the southern states to contribute their quotas to the purposes of the war. In 1784 he was sent to the legislature, where he was influential in modifying the se-

verity of the criminal code; and in 1787 he was a member of the convention that framed the federal constitution. From 1789 to 1791 he was a member of congress; and in the latter year he was placed at the head of the excise department in Pennsylvania, and held the office till after the suppression of the whiskey riots, when he resigned. In 1796 he was one of the commissioners who successfully negotiated a treaty with the Cherokees and Creeks in Georgia, after which he retired from public life. He was the first president of the Philadelphia bank, of the academy of fine arts, and of the Philadelphia agricultural society on its reorganization in 1805, all of which offices he held till he died.

CLYTEMNESTRA, in Grecian legends, the daughter of Tyndarus, king of Sparta, and Leda. After her seduction by Jupiter, Leda, metamorphosed into a swan, is fabled to have laid two eggs, from one of which were produced Pollux and Helen, said to be the children of Jupiter, and from the other Castor and Clytemnestra, children of Tyndarus. Clytemnestra was given in marriage by her father to Agamemnon, and her sister Helen to Menelaus, both sons of Atreus, king of Mycenæ; the former of whom succeeded his own father on his throne, while the latter succeeded his father-in-law on that of Sparta. During the absence of Agamemnon in the war against Troy growing out of the abduction of Helen, Clytemnestra lived in adultery with Ægisthus. On her husband's return she slew him in a bath, and also his paramour Cassandra, in alleged retribution for the loss of her daughter Iphigenia. Clytemnestra and Ægisthus were afterward in their turn slain by Orestes, son of Agamemnon. The story of Clytemnestra has been a popular theme with dramatists; among those who have used it are Voltaire in *Oreste*, and Soumet in *Clytemnestre*. It is also the subject of one of Pierre Guérin's finest pictures.

CNIDUS, or *Gnidus*, the chief city of the Dorian hexapolis in Caria, built at the extremity of the peninsula of Triopium, partly on the mainland and partly on an island connected by a causeway, forming two harbors. It was founded by a Dorian colony from Lacedæmon, had an extensive commerce, and was visited by travellers from all the Grecian cities, attracted by the worship of Venus in the temple which contained the celebrated statue of this goddess by Praxiteles. There were also temples of Apollo and Neptune. It was off Cnidus that the Athenian Conon defeated with the Persian fleet that of the Spartans (394 B. C.), thus depriving them of the command of the sea. Ctesias, Eudoxus, and Sosttratus were natives of this city, of which considerable ruins are still visible near Cape Krio. The latest explorations of these ruins were by the archæologist Newton ("Travels and Discoveries in the Levant," 2 vols., London, 1865).

CNOSSUS, or *Gnosus* (more anciently *Cnosus* or *Cnosus*, now *Makro Teikho*), the capital of

Crete in the time of Minos, built on the Cæratas, a short distance from the northern coast, and founded by Dorians, who diffused their institutions over the island. Homer mentions it as already a great city, and the residence of the celebrated Cretan king; it long maintained its preponderance, until it was weakened by the growing importance of Cydonia and Gortyna. It was renowned in mythology by numerous legends of Jupiter, who was born and married in its vicinity, of Minos, Ariadne, the minotaur, and the celebrated labyrinth of Dædalus. In later times it became a colony of the Romans. Ænesidemus the Sceptic philosopher, and Chersiphron the architect of the temple of Diana in Ephesus, were born, and Epimenides flourished here. Some masses of Roman brickwork, parts of the so-called long wall, are the only vestiges of Cnosus.

COACH (Ger. *Kutsche*, Fr. *coche*, Hun. *kocsi* [formerly *kotsi*], probably derived from Kocs [Kots], the name of a village S. of the Danube, in which coaches were made in the 16th century), a covered four-wheeled carriage, and, as usually applied, limited to those employed as public conveyances for passengers. The vehicles designated by this name, slightly altered in the different European languages from the original Hungarian *kocsi*, have been so variously constructed, that the name may properly be treated as applicable to all covered carriages, including those used upon railroads. During the middle ages the only riding practised was on horseback; and when near the close of the 15th century carriages began again to appear, they were esteemed proper only for women and invalids. The emperor Frederick III., it is stated, came to attend the council at Frankfort in 1474 in a close carriage, and the next year visited the same city in a very magnificent covered carriage. In the 16th century the German princes appear to have vied with each other in the number and splendor of their equipages. At the tournament in Ruppin in 1509, the electress of Brandenburg appeared in a carriage gilt all over; there were 12 other coaches there ornamented with crimson, and one of the duchess of Mecklenburg hung with red satin. The use of coaches, though prohibited to the feudal nobility and vassals by the orders and admonitions of the great lords, became popular throughout the states, and gradually extended to all the countries of Europe. The want of carriage roads, and the narrowness of the streets of many of the cities, were no doubt serious impediments to their introduction. Even as late as the 16th century people of the highest rank in France rode only on horseback, sometimes sitting behind their equerry on the same horse. Yet it would appear from an ordinance of Philip the Fair in 1294, forbidding citizens' wives to use carriages (*cars*), that they must have been known at that early time. About the year 1550 there were only three coaches in Paris. In 1610 Henry IV. was assassinated in his coach. The first

notice of coaches being suspended by straps is of that in which Louis XIV. made his public entrance about the middle of the 17th century. Carriages called whirlicotes were in limited use in England in the time of Richard II. His mother was conveyed in one on the flight of the royal family in the rebellion near the end of the 14th century. The introduction of coaches into England has been credited to Sir Thomas Chamberlayne, who was ambassador to the courts of Charles V., Philip II. of Spain, and the king of Sweden, and who, according to some, also introduced watches. But there is doubt on both points. Others say that Fitz-Allan, earl of Arundel, introduced coaches in 1555. Stow says that they were introduced in 1564 by a Dutchman, who became coachman to Queen Elizabeth. He adds: "After a while, divers great ladies, with as great jealousy of the queen's displeasure, made them coaches, and rid in them up and downe the countries, to the great admiration of all the beholders; but then by little and little they grew usual among the nobilitie, and others of sort, and within twentie years became a great trade of coach making." In 1619 the duke of Buckingham used one with six horses, and the earl of Northumberland, to ridicule this pomp, appeared in one with eight horses. The period in which coaches became familiar can therefore be referred but little further back than the time of the settlement of New England; and for a century afterward the use of private carriages in the country was limited to the aristocracy and wealthy classes. In London coaches began to be kept for hire in 1625. In 1673 there were 20 hackney coaches in Edinburgh, but the narrowness of the streets or state of the roads must have rendered them comparatively useless, for in 1752 there were only 14, and in 1778 only 9, while the number of sedans increased. The conveyances through the interior were the cumbersome stage wagons, used for carrying goods, in the tail of which, as it was called, was reserved a covered space for six or eight passengers, who sat upon the straw on the floor. In the reign of Charles II. stage-coach travelling was so poorly conducted, that two days were spent in going from London to Oxford, 58 miles; and in 1703, when Prince George of Denmark went from Windsor to Petworth, about 40 miles, to meet Charles of Austria, pretender to the throne of Spain, the journey occupied 14 hours, 6 of which were spent on the last 9 miles. The fact is spoken of by the historian as the more surprising, inasmuch as, except when overturned or stuck fast in the mire, his royal highness made no stop during the journey. In the middle of the 18th century the journey from London to Birmingham, 116 miles, occupied nearly three days by the stage coach; and the first regular public conveyance of the kind between London and Edinburgh was established in 1785, when "a two-end glass coach machine, hung on steel springs, exceeding light

and easy," was advertised to go through in 10 days in summer and 12 in winter, the passengers lying over the included Sabbath at one of the villages on the route. The modern mail coaches, running over splendid turnpike roads, making 10 miles an hour, and changing horses at every stage, were the finest in the world; but they have been superseded by the network of railways covering the country. At Amsterdam the use of wheel coaches was prohibited in 1663, on account of the injury they did to the expensive pavement; and the bodies were consequently placed on runners, as they are used in cold countries upon the snow.—Numerous forms of covered carriages have been introduced during the present century; too many indeed to be enumerated in this article. Hackney coaches drawn by two horses have generally given place in London to the one-horse cab or cabriolet, which came into use in 1823; but in the cities of the United States the former are altogether preferred. The long coach called an omnibus, with the entrance behind and seats along the sides facing each other, originated in Paris in 1827, and in 1831 it began to come into use in London. In large cities it is found the most economical form of carriage, except those running on rails, for conveying the largest number of passengers through the streets. In Paris the public omnibuses are numerous and commodious, though their progress is slow as compared with those of London. One company has a municipal monopoly and owns all the lines. The omnibuses on the several lines are of different colors, and the lines are lettered from A to Z, and from AB to AC. In 1872 there were in London about 1,500 omnibuses, employing nearly 7,000 persons. The number was formerly much larger in proportion, for in 1844 one company employed 1,400 omnibuses; but a large part of the city and suburban travel is now carried on tramways and underground railways. In New York city one was made in 1830, and run upon Broadway. In 1858 the number of these coaches employed upon various lines was 429. This was a considerable reduction from the number of former years, owing to the construction of horse railroads; and by 1873 the number was reduced to about 200. Before the introduction of railroads, post coaches were largely employed upon the public roads; and the demand for them in all sections of the country caused large establishments for their manufacture to grow up where the skill, capital, and materials required could be best secured. Active competition led to continual improvement, and the carriages became models of perfect construction, combining strength with lightness and gracefulness of form, together with comfort to the passengers, in a manner unequalled in any part of the world. They are made for carrying nine passengers upon three seats inside, two with the driver upon the "box" in front, and three upon a seat behind this on the front edge of the top. The manufacture of stage

coaches in New York, New Jersey, and New England has much decreased within a few years, but large numbers are still made, especially at Concord, N. H., for hotels, transfers, and for export to the far west and to Mexico and Central and South America. The French diligences are unwieldy vehicles, and only adapted for smooth roads. They are formed in three compartments, the front one called a *coupe*, having a seat for three persons facing forward; the middle apartment, the *intérieur*, has seats for six, like a hackney coach; and behind this is the *rotonde*, with seats for six or eight passengers, who sit with their backs to the sides of the carriage. On the front part of the top is the *banquette*, sometimes covered with a hood, with seats for four passengers. The driver rides one of the horses, of which five or six are commonly employed.—Few pieces of mechanical work require so great and varied skill as the construction of coaches. Their use demands lightness, and yet they must withstand the roughest service. They are to be subjected to continual strains and wrenchings, coming from every direction, exposed to all extremes of dryness and moisture, heat and cold, and used where repairs may be impracticable. The best materials are therefore selected and shaped with mathematical exactness. The frame is the nicest piece of joiner's work, made with the toughest ash, that has grown in exposed situations, and been hardened by a seasoning of two years or more. Oak and hickory, equally well prepared, are adapted for much of the work; and to the excellence of the latter wood may be referred some of the superior points of American coaches. The planking is of strong elm, and the panels of the light but stiff Spanish cedar. Mahogany and rosewood are also sometimes used; and for the same and other purposes, pine, bass, and lancewood. The frame, axles, &c., are thoroughly ironed with pieces of the best refined metal, made and fitted especially for this purpose, and often tested by severe strains. The springs require the best of steel. The leather employed is prepared for this particular use, and is of various kinds, from the heaviest harness leather to the fine enamelled and morocco for upholstery. Fine cloths, silks, damasks, plushes, &c., in great variety, are used for the lining; and an especial fabric called coach lace has long been a considerable article of manufacture in New England, for parts of the trimming and the holders. The preparation of many of these and other articles for the express purpose are subjects of distinct trades. Of all parts of the coach, none call for greater skill in their construction than the wheels. The spokes are placed to receive the whole weight and shock of the carriage, always in the direction to compress longitudinally the fibres of the wood, while no more of this is left to add to the weight than is necessary. The greatest ease of draught requires large wheels, but also that

the line of draught from the shoulder of the horse to the level of the centre of the forward axle should incline at an angle of 15° with the horizon. This limits the size of the forward wheels to from 40 to 44 in. in diameter, and requires that the horses should then work as closely as possible to the carriage. The hind wheels are from 50 to 56 in. in diameter, and the width of the track 4 ft. 8 or 4 ft. 10 in. The nave of the wheels is lined with a metallic box ingeniously contrived to exclude dust, secure the wheel from running off, and retain a supply of lubricating oil. For coaches designed for rough roads, leather straps are used to support the body, and these are secured to upright steel springs upon each axle. The painting of the body is probably a more elaborate process than is practised upon any other work. Three or four coats of priming in common oil color are successively applied, and after this as many more of white lead and yellow ochre for a body. The surface is afterward rubbed smooth with pumice stone and water, when it is ready for the selected colors and ornamental designs. Over these are laid several coats of copal varnish.

COACH-WHIP SNAKE (*psammophis flagelliformis*, Catesby; genus *masticophis*, B. and Gd.), an American species characterized by a

Coach-whip Snake.

long and narrow head, projecting upper jaw, superior orbital plates large and projecting much over the eyes; nostrils large, lateral, and near the end of the snout; eyes large, iris dark gray; neck small, body long, and tail attenuated like a whipcord, which it also resembles in the braided appearance produced by the arrangement and dark border of the scales. The scales are smooth and usually have two points at the apex; on the neck they are small, on the fore part of the body narrow and rhomboidal, on the tail short and broad. The color of the head, neck, and one-third of the body is glossy black, becoming paler toward the tail, which is tawny brown; the scales on the tail have dark margins; the lower surface in front is bluish slate, behind white clouded with brown; the colors vary in their shades, but near the head it is always black. In a specimen 61 in. long, and $2\frac{1}{4}$ in. in circumference, the head was $1\frac{1}{4}$ in., the body 44 in., and the tail 16 in.; the abdominal

plates were 203, and the sub-caudal scales 109 pairs. It sometimes attains the length of 7 ft. It moves with great swiftness, and feeds on young birds and small animals; though inoffensive to man, it defends itself bravely, twining its long folds around its enemy. This species is rare, and appears to be confined to South Carolina, Georgia, and Florida. In its general form, in the scales, and in the plates on the head, it somewhat resembles the black snake. It receives its popular name, not from the small size of the body and tail, but from the imbricated disposition of the caudal scales.

COAHOMA, a N. W. county of Mississippi, separated from Arkansas by the Mississippi river; area, 750 sq. m.; pop. in 1870, 7,144, of whom 5,381 were colored. The surface is low and level, and the western part is frequently inundated by the Mississippi. The Sunflower river flows through it, and Cold Water river through the N. part. The soil is generally good. The chief productions in 1870 were 151,985 bushels of Indian corn and 11,456 bales of cotton. There were 507 horses, 939 mules and asses, 1,184 milch cows, 2,688 other cattle, and 5,066 swine. Capital, Friar's Point.

COAHUILA, or **Cohahuila**, a state of Mexico, between lat. 24° 17' and 29° 43' N., and lon. 100° and 103° 30' W., bounded N. and N. E. by Texas, from which it is separated by the Rio Grande, E. by Tamaulipas and Nuevo Leon, S. by Zacatecas, and W. by Durango and Chihuahua; area, 58,920 sq. m.; pop. in 1869, about 96,000. The surface is rough, being intersected by several ranges of mountains which traverse it from N. W. to S. E. The only plain of any extent is in the W. part, and is called the Bolson (sack) de Mapimi, from the peculiar manner in which it is enclosed, having no opening excepting on the north. Several tribes of savage Indians overrun this plain, to the serious detriment of the farmers and miners. Villages and farms once prosperous have been abandoned in many instances by their inhabitants, as the only means of escaping their ferocity. A large part of the remainder of the state consists of rough mountainous country, and desert plains without wood or water; but there is much good grazing land, and except for the insecurity consequent upon the proximity of the savages, cattle might be extensively raised. In the Bolson de Mapimi are Lakes Mapimi or Caiman and Parras. The river Mapimi flows into the former, and the Rio Grande del Parras into the latter; both are small streams. The Salada, Sabinas, Toya, and Meteros, all affluents of the Rio Grande, are inconsiderable. Silver mines exist in the mountains, but few are worked on account of the lack of sufficient capital and hands, and the depredations of the Indians. The land adapted for tillage is limited, but when quietly possessed is well cultivated and yields abundantly. The chief cereals are maize, wheat, and barley. In the S. part the maguey (*agave Americana*) is cultivated in large plantations. Parras and its

vicinity are famous for their vineyards and the excellent quality of their wine. Brandy of high repute is also manufactured in considerable quantities. There are some large landholders in Coahuila, who would be very wealthy could their property be protected, but who are comparatively poor in the insecure condition of the country. The wines and liquors already mentioned, with coarse cloths and pottery, form the only manufactures; and the exports consist of wines, wheat and other grains, mules, horses, buffalo tongues, ox hides, deer skins and horns, wool, silver, iron, copper, amianthus, sulphur, and other minerals. Saltillo in the southeast, on the river Tigre, is the capital. Seven miles S. is the site of the battle of Buena Vista. (See BUENA VISTA.) The other principal towns are Monclova or Coahuila, Santa Rosa, and Parras.

COAITI, a South American mammal, formerly placed among the *viverridæ*, but now considered as coming near the raccoon, which it resembles in general appearance, habits, and diet. There are two species, the red and the brown, both remarkable for the great length and mobility of the snout; they live among the branches of trees, being very expert climbers, where they feed upon birds, and their young and eggs, on

Coati-mondi (*Nasua rufa*).

insects, and sometimes on vegetable substances. The red coati (*nasua rufa*) is of a general reddish chestnut color, with black ears and legs, maroon-colored bands on the tail, and white hairs on the edge of the upper jaw; the fur is harsh, and of little use; the paws are provided with peculiar tubercles, which give it firm foothold on the branches. It is a nocturnal animal, hiding by day; it may be tamed, though its temper is very capricious; the feet are 5-toed, with sharp claws. This species is often called "coati-mondi." It is smaller and more weasel-like than the raccoon. The brown coati, or quaschi (*N. narica*), is of a browner color, with the lower parts and inside of limbs tinged with yellowish gray. It is a lively and amusing animal, easily tamed, and useful as a destroyer of rats and mice in the

house, and of slugs and snails in the garden; it lives in the same region as the other species.

COAL, a black, opaque, inflammable substance, generally hard and compact, though laminated and stratified in beds between layers forming the crust of our earth. Coal has become one of the essential elements of modern civilization; in fact, the progress of the civilization of a country is now recorded by the amount of coal obtainable and employed by the inhabitants in a given time.—Mineral coal is a compound especially of carbon or of decomposed woody matter, with inflammable substances and hydrogen and oxygen gases. According to the different proportions of the volatile matter, in common language inaccurately called bitumen, the coal has a somewhat different aspect, flames more or less rapidly and actively, and develops heat in different degrees. These differences have served as a basis for a kind of classification of the coals, which, though scarcely limitable in its divisions, is generally admitted for common use. The more essential of these divisions are the following: 1. Anthracite or glance coal, a very hard, compact, lustrous, grayish black mineral, breaking in conchoidal fracture, though still bearing evidence of its original lamination. It burns slowly, with little or scarcely any flame, producing a high degree of heat. On account of the minute proportion of volatile matter in its composition, the coal is also called non-bituminous. When this coal is somewhat less dense, and has an increasing amount of volatile matter, it burns with more flame, and is then semi-anthracite. 2. Bituminous coal, though still hard, breaks more easily and more irregularly, often dividing into large cubic pieces in the plane of stratification and by cleavage. It is generally quite black, still with some lustre, contains less carbon with a larger proportion of inflammable substances than anthracite, and therefore takes fire more easily and rapidly, and burns with a bright yellow flame, developing less heat. The amount of volatile combustible matter in its composition is extremely variable, and therefore its appreciable characters, either in its value as a combustible material or in its appearance, vary in the same degree, considerably blending the classification and multiplying its names. With a moderate proportion of inflammable gases it is dry coal; with more bitumen it becomes fat coal, which passes to caking coal when in burning the matter soft-

ens and coalesces like paste. Of the moderately bituminous coals, the best known in America is called semi-bituminous, of which very large quantities are produced from the Cumberland district of Maryland, and the Broad Top, Clearfield, and Blossburg districts of Pennsylvania, along the S. E. margin of the Alleghany coal field. Of the more highly bituminous coals the most valuable is the splint or block coal of N. W. Pennsylvania, Ohio, and Indiana, which owing to its peculiar structure can be used in its raw state in the blast furnace. 3. Cannel coal is also a kind of bituminous coal. It differs much from the numerous other varieties by its fine, equal, compact, homogeneous texture, resembling a dusky black paste hardened to a mineral substance or to stone. It breaks therefore with a conchoidal fracture, and is at once distinguished from the other kinds of bituminous coal by its equal, non-laminated structure, or the absence of those horizontal thin layers which in the common kinds of bituminous coal are seen alternating in different degrees of lustre and apparent density. By distillation it yields a larger proportion of mineral oil than any other coal. Sometimes it is so highly bituminous, as in the case of the Breckinridge coal in Kentucky, that it is dangerous to use it in steamboats, or in grates through which the oil percolates when inflamed. It burns like candles, and hence its name.—If the more marked characters which indicate the several species of mineral coal are easily recognized at first sight, and if everybody knows the bituminous coal from the anthracite or the cannel, it is not the less certain that, considering the matter in itself and in its compounds, coal is an indivisible whole. Not only have all the kinds of coal the same constituent chemical elements, merely varying in proportion in a slight degree, but all the varieties of coal, of bituminous especially, are found in some localities in the same vein. Anthracite passes to semi-anthracite, and this to bituminous coal, by inappreciable degrees. The coal beds of Shamokin and Trevorton in Pennsylvania give anthracite and semi-anthracite. The Spadra coal of Arkansas is semi-anthracite at one place and bituminous at another. In Kentucky some veins have one half of their thickness bituminous, the other half cannel; or at other localities, as for example on the Louisa river, the miners work bituminous laminated coal at one

marine animals, attesting the dependence of animal upon vegetable life, or at least their relation to it. Rich deposits of mineral oil are found also in the rocks of this period, especially in the Niagara limestone. At Chicago, for example, this rock is completely saturated with oil. The Salina and lower Helderberg periods are generally composed of deep marine formations, where of course remains of plants are very rare, as seaweeds do not live at a great depth. Even the Salina formations have few animal remains. But the last period of the Silurian formation, the Oriskany, manifests its vegetable life not only by remains of marine plants, but near its upper part by the first traces of land vegetation, recognized in fragments of a species referable to the lycopods or club-moss family, and similar in size at least to the ground pine of our woods, *lycopodium selago* and *L. lucidulum*. They are the earliest representatives as yet known of a family of plants to which belong the genera *lepidodendron*, *sigillaria*, &c., which come later, and, by the great number of their species and the enormous size of the trees generally representing them, are called to play at a subsequent period a remarkable part in the formation of coal. From the beginning of the Devonian, the corniferous, vegetable remains appear in the strata in a far greater abundance, especially those of marine plants, together with a proportionately increased supply of mineral oil. It is the epoch of the cauda-galli grit, so called from the distribution in the rocks of a large fucoid which covers with its debris wide surfaces of shales and fills strata of great thickness. This plant passes up through the whole Devonian to the base of the carboniferous. The bitumen has been during this period treasured in large crevices of the rocks, in cavities wherefrom it is now pumped out and utilized. The oil wells of Canada come from deposits in the cauda-galli formation; in New York the cavities of the corniferous limestone, even those which have been formed by the decomposition or destruction of fossil remains, are filled with mineral oil. Above the corniferous, the black shales, the Marcellus and Genesee shale of the Hamilton period, are everywhere impregnated with bitumen, from which they receive their black color. The combustible matter is abundant enough to percolate through the fissure with water; it is also obtained from the shale by distillation. Even these black shales have been used for fuel, giving a bright flame, though they do not consume. They have been constantly searched for coal; but no coal has been found in this formation, which from its fossils is evidently of marine origin. With the bones and teeth of large fishes, it has also the remains of seaweeds to which its bituminization is due. Some scattered trunks, of conifers especially, and mostly silicified, have been dug out of the black shales of the Hamilton period. They seem to have been floated and deposited along low shores by the waves

or the current of the sea. In a few localities in Canada ferns and other plants have been observed seemingly deposited in place. But nowhere has the land vegetation been luxuriant enough to produce coal, though the genera, if not the species, represented by these plants are closely allied to those of the carboniferous period. The upper Devonian, especially the Chemung, presents by its vegetable remains the same character as those of the former period; but the land vegetation becomes more and more predominant, yet not enough to produce coal. Moreover, most of the upper Devonian strata represent beach formations by their red shales. These formations have a distinct flora, far different in its typical characters from that which is recognized in the composition of coal. These extensive mud beds washed by the tides, alternately above and under water, were preparing a solid basis for the land, or a ground for the remarkable period which was to follow. —The carboniferous period, as the word implies, is essentially that of the coal formation. Its lowest part, the subcarboniferous, is its foundation, laid upon the mud beds of the Devonian. In the east of the North American basins, it is composed of thick strata of hard red shale and sandy rocks; in the west, of beds of hard compact limestone and sandstone, overlaid by the successive stages of the carboniferous in a thickness of 2,000 to 3,000 ft. From the base of the subcarboniferous measures, the land plants already in abundance appear, in ascending, in a constantly increasing proportion, while the marine plants disappear in the same degree. The composition of the first or of the lowest bed of coal indicates only the remains of land plants, which henceforth, in the whole thickness of the coal formations, constitute the vegetation; at least no remains of marine plants have been found in connection with the coal, or appear to have contributed to its composition. From the millstone grit to the Permian, the shales are mostly covered and filled with fragments of plants, which without exception belong to the species of the coal or land flora; and in some beds of sandstone also we find local deposits of trunks now silicified or petrified, all representing species of ferns, *lepidodendron*, *sigillaria*, *calamites*, &c., to which the coal plants are referable. The first coal beds appear in the upper part of the subcarboniferous, or somewhat lower, a short distance below the millstone grit, a formation composed of sand and pebbles agglomerated, and for this reason named conglomerate, which generally underlies the productive measures as well in Europe as in America. Under the millstone grit a few beds of coal have been formed locally, two, rarely three, not of great thickness nor of wide extent, sometimes merely in pockets, as they are called, the matter transformed into coal having filled deep hollows of an irregular bottom and of small area. In Arkansas, however, the whole coal-bearing measures are under the

millstone grit, and generally contain two beds of coal, even sometimes three of wide extent, and varying in thickness from 1 to 4 ft. In eastern Kentucky and Tennessee, also in Indiana, two lower coal beds 2 to 3 ft. thick are found under the conglomerate, in near proximity to its base; and in Illinois a lowest bed of coal has been observed under the Chester limestone, an upper division of the great limestone formation which there underlies the coal measures. Coal is found in Nova Scotia, in Scotland, and in Russia also below the millstone grit. But it is only from the millstone grit upward, and in a thickness of 300 to 1,000 ft. of measures, according to the localities, that coal beds are formed of great thickness and of wide extent. The second bed of coal above the conglomerate (B) is generally composed of two or three different beds, either united in one or separated by beds of shale or even of sandstone. This bed is found over nearly the whole extent of the coal measures from Missouri to eastern Pennsylvania, and even to Massachusetts and Rhode Island. Its thickness is rarely under 3 ft., more generally 6 to 7 ft.; at Straitsville in Ohio it is 12 ft.; it is 30 ft. or more in some localities of the anthracite basin of Pennsylvania. From the millstone grit upward, in a thickness of from 500 to nearly 1,000 ft., coal beds are formed of various thickness and extent, alternating with strata of shale, limestone, sandstone, &c., up to the great Pittsburgh coal, which is, near the end of the productive carboniferous formation, what the big vein is near its beginning. The Pittsburgh bed covers, in Pennsylvania, Virginia, and Ohio, an area estimated at 20,000 sq. m., preserving generally a thickness of 4 to 6 ft., and often greater. Between the millstone grit and the Pittsburgh coal, five to twelve veins are generally found in the measures. Of course the productiveness of the measures is locally very variable. It is at its utmost in the anthracite region of Pennsylvania. At Plymouth, near Wilkesbarre, for example, where the big vein is 30 ft. thick, a section of 300 ft. of measures has 50 ft. of coal in five veins. At Scranton a section of 350 ft. indicates 60 ft. of coal in eight or nine beds. Here the largest vein is 14 ft. In the same region a section of 800 ft. has nearly 70 ft. of coal distributed in 15 beds. In the bituminous coal region of Pennsylvania and Ohio, as well as in the coal basin of Indiana and Illinois, the thickness and number of the beds of coal are somewhat reduced, as is also the thickness of the measures; but there is a remarkable relation between the formation of the coal beds and that of the intermediate strata. In the north at least, or with the exception of the Virginia coal fields, the relation indicated above is, with little difference, as one foot of coal in 18 to 22 ft. of measures; or in 500 ft. of coal measures there is generally an average thickness of 25 ft. of coal, distributed of course in several beds of various thickness. From the Pittsburgh coal

above and for nearly 1,000 ft. of measures the productiveness of the carboniferous formation diminishes in such a way that, though several coal beds have been observed, they have scarcely been found anywhere of a workable thickness. The reverse of the fact remarked in the subcarboniferous, where as the land plants become more numerous the deposits of coal also increase, is seen in passing higher up above the Pittsburgh coal to the end of the carboniferous. The plants which by their components and their great size contributed most to the formation of the coal, the *lepidodendron*, *sigillaria*, &c., decrease in numbers and even disappear. Several species of the carboniferous period are seen still persisting later, even in the Permian epoch; but these species are merely ferns and calamites, which, though large and abundant enough, do not seem to have formed any dense agglomerations of woody material, like those which evidently covered the surface of the earth when the vegetation was in its full vigor.—The strata intermediate to the beds of coal are composed of sandstone, sometimes hard enough to be cut in blocks and used for building, sometimes soft and passing to shale; of limestone, iron ore, clay, and bituminous shale. Most of the coal beds rest upon a bottom of grayish or whitish soft clay, generally mixed with remains of the *stigmaria*, a floating plant, the most common in the coal measures, which seems to have entered largely into the composition of the clay and of some kinds of coal. The bottom clay varies in thickness from a few inches to more than 30 ft. When penetrated by ferruginous solutions, it becomes reddish, and is sometimes hardened to such a degree that it resembles limestone and breaks under the hammer like hard rock. It is the rotten limestone of the miners. Very rarely the coal beds are in immediate superposition to sandstone; none have been seen as yet upon limestone without an intermediate bed of clay. In most cases, as a coal bed becomes at its base mixed with clay which at the point of contact is black, hard, and bituminous, it passes at its upper surface into black bituminous shale or slate differently composed from that of the bottom, laminated like the coal, or in thin layers and mixed with remains of the plants which have entered into the composition of the coal. These shales, however, do not always occur, and therefore the roof of the coal is often sandstone, or more rarely limestone. With the remains of plants, the roof shales have also fossil shells, bones, or teeth of fishes. The limestone beds of the coal have rarely if ever remains of plants, but often a great quantity of animal remains, coral, crinoids, fishes, and especially shells. As will be seen hereafter, the distribution of all these kinds of strata is normal and explainable, as is also the formation of the shales, which are seen not only as the roof of the coal beds, but interlying them, and unfortunately sometimes in numerous al-

ternate layers with which the pure coal is so closely mixed that these coal strata are not workable. It is to the increasing thickness of these interlying clay partings, as they are named by the miners, that the subdivision of the coal beds is mainly due. Frequently coal beds are seen in one bulk at one place, and in another, divided into two by a clay parting, which by and by thickens to 10 or 20 ft. or more, and thus separates the coal into two distinct beds.—As remarked above, the Permian, at least in America, has no coal. The characters of this formation are somewhat similar in the nature of the rock to those of the subcarboniferous, mainly consisting of red shale, limestone, and sandstone. With some species of ferns of the coal measures, its flora is represented by large calamites, a genus whose species have the texture and outside form of the horsetail plants of our time, but of an immense size, and especially with new types of conifers. In North America the Permian formations are mostly composed of thick strata of magnesian limestone, overlying the upper coal measures of the west, near and along the Missouri river, especially in Kansas, and also in the Rocky mountains, where it generally underlies the cretaceous formation. The triassic period, in ascending, follows the Permian. It is represented in North America, especially in Nova Scotia, Connecticut, New Jersey, and Pennsylvania, by deposits of red hard shale with few fossil remains, and in North Carolina and Virginia by the same kind of rocks, containing however beds of combustible mineral or of coal. The coal of Richmond, that of Deep river and Dan river, is worked out of beds 4 to 6 ft. thick, and is reported to be of good quality. In connection with the coal strata, and in their roof shales, remains of fossil plants are found in profusion, indeed in the same position and in the same abundance as the remains of plants are seen in the true coal measures; but they represent far different species. With some ferns of a peculiar type, the fossil plants of the trias are mainly species of conifers, and in the greatest proportion species of *cycadææ*, a family which is predominant also in the flora of the Jurassic period. Of this period, which in Europe is a formation of immense thickness, we have little in America. It has been recognized in the Rocky mountains in some beds of limestone. In one of its divisions, the oölitic, it has some fine deposits of coal in England. These beds, like all the coal beds, are overlaid by black shale imbedding vegetable remains, which mostly represent species of *cycadææ* and of ferns.—Over the Jurassic we find the cretaceous. Like those of the upper Devonian, the subcarboniferous, and the Permian, its strata are mostly marine and submarine (beach formations), denoting an epoch of subsidence to prepare, after the destruction of ancient races of plants and animals, a new organic world by great changes in the atmospheric and surface circumstances of the earth. Forma-

tions of this kind have no coal. Their vegetable remains are mostly marine, and in the cretaceous they are locally present in connection with strata impregnated with bitumen. This is the case in California. The cretaceous formations of North America are extensive, and are distributed from the upper Missouri to the base of the Rocky mountains, where their thickness reaches 2,000 to 3,000 ft. The lower part, that which has been named the Dakota group from its predominance in that territory, is composed of red shale, and is evidently a beach formation immediately overlying the Permian. Though this group has no coal, but merely thin streaks of black bituminous shale, it is remarkable for its remains of fossil plants, which most of all represent dicotyledonous species. As high as the base of the cretaceous no plants of this vegetable division have been recognized. From the first appearance of land plants at the base of the Devonian, up to the cretaceous, all the species represented by their remains are referable to cryptogams and gymnosperms, these comprising the cycads and the conifers. But all at once in this Dakota group, which in America is the lowest cretaceous, we find an abundance of leaves of dicotyledonous species, sassafras, sycamore, oak, tulip tree, &c., without any remains of the former precedent and prominent types. From the Dakota group upward there is a succession of cretaceous sandstone and black shale, whose fossils are all animals, mostly large shells of species indicating a deep marine formation; and upon this a succession of thick beds of coarse hard sandstone, somewhat similar by its compounds to the millstone grit of the carboniferous, containing, especially in the intermediate layers of shale, a great abundance of fucoids and broken fragments of wood, stems, &c., appearing as brought up and mixed with the sand of the shores by the waves.—Further west, and along the eastern base of the Rocky mountains, this sandstone formation is the lowest stage of the tertiary period. It points by its compounds to the slow upheaval of a new land, and opens a new epoch where the conditions for the production of coal appear nearly as favorable as they were during the period of the true or old carboniferous formation. Along the base of the Rocky mountains, and in the high valleys of the interior of the chain, from the Rio Grande in New Mexico along the Pacific slope to Alaska, coal beds of the lower tertiary cover wide areas, and are sometimes of great thickness. In Colorado the veins now actively worked vary in thickness from 4 to 15 ft. At Evanston, Utah, the main coal, interlaid with bands of slate, is 26 ft. thick. The succession of the strata and their distribution is also remarkably similar to that of the carboniferous measures. At Marshall's, for example, in Colorado, an exposed section of 450 ft. of measures indicates 60 ft. of coal distributed in nine or ten veins, the lowest 14 ft. thick, separated by strata of sandstone, iron ore, clay,

shale, &c., as are the coal beds of the carboniferous measures. Here also most of the beds of coal, if not all, are underlaid by soft white or gray clay, sometimes pure and used for pottery, like the clay of the carboniferous, sometimes dark-colored by heaped fragments of radicles of water plants. The shale and sandstone strata generally contain a profusion of remains of land plants, whose characters, related to this period, are far different from those of the carboniferous. They mostly represent palms with dicotyledonous species, oak, poplar, walnut, hickory, magnolia, cinnamon, &c. The flora of these tertiary measures of North America has afforded already many hundred species of fossil plants.—The combustible matter or the tertiary coal, often called lignite, is in its aspect scarcely distinguishable from true coal. At some localities, especially in the upper part of the measures, it is softer and more easily broken; but at others the matter is hard, compact, distinctly laminated in thin alternate layers of crystalline and more opaque matter, gives much heat by combustion, the best kinds in some localities, as at San Pete in Utah, even producing good coke, and when the beds are in proximity to upraised dikes of basalt or lava the coal is transformed into anthracite. Nothing then distinguishes this tertiary lignite from true coal but a less proportion of carbon in its compounds, and this can be recognized by chemical analysis only. The constituents are the same; only in the lignitic coal the decomposition is not as far advanced, as will be seen by comparing the analyses of the different combustible materials. In the upper tertiary, beds of lignite coal are still found, but they are less predominant, diminishing in number and thickness and in the extent of the area which they cover. The materials also in ascending gradually appear in a less advanced stage of decomposition.—In Europe lignite beds of the upper tertiary represent mere deposits of wood, especially trunks of trees transformed into a black soft substance, which preserve still the vegetable forms and also the texture of the wood, as well as if the trees had been recently cut. Later still, or rather nearer to our present epoch, the composition of the beds of lignite becomes undistinguishable from peat. To complete the similarity, old peat beds, as is especially the case in Holland, are found under thick strata of clay or sand, in two or more successive stages, or under thick gravel deposits of the drift of the quaternary. The material is mere soft peat, which by drying becomes hard as stone, and a combustible nearly as good as lignitic coal. Along the Ohio river and at various places in Ohio, Indiana, Illinois, &c., we find thick peat deposits in the clay of the drift. The bottom of the bed is clay; the combustible matter is true peat; the beds overlying it are generally hardened clay wherein leaves, nuts, acorns, &c., are found, most of these vegetable remains being already

carbonized or hard and black as coal, as in the roof shale of the coal measures. In some localities trunks and branches of trees are imbedded in these clay formations; the woody substance of these vegetable remains is already softened and decomposed, and its place taken by the infiltration of clayey matter. They only need the hardening done by time to become fossilized trees, and henceforth, after the drift period, we have as representative of the carboniferous formations peat bogs of different ages: some very thick, overlaid by strata of humus or of sand or gravel; some more recent, covering the ruins of monuments of the human race, bridges, roadways, aqueducts, &c., or holding in their matter bones of extinct or nearly extinct races of animals, like those of the aurochs, with utensils, weapons, and ornaments, attesting the existence of races of men now unknown. But some deposits of peat are so recent that their beginning is positively remembered by old men, who have seen them grow to some thickness where as children they had seen only stagnant pools, or a forest, or a muddy swamp. All these peat deposits, like the beds of coal and of lignite, are found in connection with vegetable remains which are either dead and cover them entombed in the clay of their surface, or are still living and deposit and heap their woody matter upon them, thus constantly increasing their thickness. We must therefore acknowledge that from the beginning of what we call the geological formations, or from the base of the Silurian to our time, remains of plants are found in intimate connection with all the deposits classed under the denomination of combustible minerals: marine plants or seaweeds, with the strata containing oil or bitumen; land plants, with the deposits of coal in all its degrees of hardness and perfection, from the soft peat, which is merely unripe coal, to the hardest anthracite.—The origin of the coal, or at least its essential composition, is apparent from what has been said of its geological distribution. The first hypothesis thrown out on the subject was that the coal was a mere mineral or bituminous compound deposited and distributed in the series of the rocks like strata of other nature. As it is mostly in concordant stratification with them, it was therefore considered to have the same origin. But the formation of the strata of the earth is easily accounted for: the sandstone by erosion of primitive rocks, the removal, transportation, and deposition of the matter; the limestone by the submarine action of animal life, &c. As free bitumen does not exist in nature, deposits of bitumen in the rocks are an anomaly as long as the origin of bitumen cannot be positively indicated. Moreover, there is a great difference between bitumen, or rocks impregnated with bitumen, and coal beds. Hardened or oxidated bitumen has been found in a few instances filling crevices of rocks, as in Canada and in West Virginia; the matter is homogeneous, either semi-pellu-

cid, like dark-colored glass (the albertite), or a dull black compound comparable by its appearance to cannel coal (the grahamite), but filling holes, without concordance of stratification with the rocks wherein it is deposited, and proved by chemical analysis to be mineral oil oxidated and thus solidified by long exposure to atmospheric influence. Cases of this kind explain nothing concerning the origin and nature of coal, and therefore the first hypothesis was soon set aside.—That coal is composed of woody matter or of vegetable remains is easily recognized by ocular examination. In carefully inspecting a piece of coal the observer will in most cases see it formed of thin parallel layers of semi-transparent or crystalline matter, alternating with more opaque, earthy ones of the same thickness. These layers, about the tenth of an inch thick, are distinct enough to be counted like the rings indicating annual growth upon the horizontal section of a tree; and this even upon anthracite as well as bituminous coal. In splitting a piece of coal in the plane of stratification or of the layers, the exposed surface generally bears a pulverulent matter resembling charcoal; and this under the microscope is seen to be composed merely of vegetable fibres. Often the original form of the plants from which these woody fibres are derived (bark of *lepidodendron*, *sigillaria*, calamites, leaves and stems of ferns, &c.) is visible to the naked eye. In some cases a piece of coal a few inches square is seen with its faces covered with branches and leaves of ferns perfectly distinct in their outline and nervation; and in that way as many as five species have been identified upon the same surface, from their carbonized skeletons. In other cases, as in cannel coal, the fibrous texture of the matter cannot be recognized at first; but if thin layers of such coal are exposed to the action of a strong acid, the black bituminous substance is dissolved and the fibres are exposed whitened and distinct. Interesting researches have thus positively established the fact that coal is composed of vegetable debris. This conclusion agrees with the facts recorded above in regard to the distribution of the coal strata, which in the geological formations of all the epochs have been seen always in connection with vegetable remains.—But the essential fact, the origin of coal from vegetables, being admitted, the mode of nature's proceeding is not yet explained; and the question is still, whence have been derived the woody materials for the composition of the coal, and how have they been brought together and heaped in such immense masses of combustible as are represented by coal beds 10 to 20 ft. thick or more, extending over areas of many thousand square miles? Only two hypotheses are worth considering: that of the transportation and heaping of woody materials by water, and that of the growth of the materials upon the same surface now occupied by the coal beds. The first theory presupposes

that forests growing upon slopes along lakes or seashores had been torn down by whirlwinds, and that the trees had been then carried by floods to the bottom of the lakes or to the sea, and there entombed and transformed into coal. This hypothesis could scarcely account for the formation of coal beds of very small extent. In the transportation of trees or vegetable remains by water, a large proportion of sand, mud, &c., would of course have been swept down with the forests, and mixed in the deposits with the wood, rendering the matter very impure. Moreover, the coal deposits are generally in flat basins of wide extent, and an equal distribution of the trees in horizontal layers is an impossibility by transportation of this kind. Another difficulty in the amount of woody matter which enters into the composition of a coal bed is not generally known, and is far above every hypothetical calculation. Considering areas of the same extent, a coal bed 6 ft. thick is equivalent to all the wood which could be produced by a forest in 2,400 years, and this supposing that, as is done in the government forests in France, all the wood should be cut in its prime and the cultivation of the forests cared for in order to force the productiveness to its highest degree. Some beds of the carboniferous measures of North America, the Pittsburgh coal, and the big vein, with an average thickness of 6 ft. at least, cover an area of more than 20,000 sq. m. Who would dare to suppose the production of such a mass of vegetation along a river, its carriage to the sea for 2,400 years, and its deposition upon a continuous surface in horizontal strata of an even thickness? Moreover, the lamination of the coal, its horizontal and continuous extent over wide areas, the formation of the shale above the coal (shale generally mixed with an abundance of vegetable remains, some of them very large), the presence of standing trees or standing petrified forests either in the clay beds under the coal, or even imbedded in the coal beds, or rooting in the clay beds above—all these facts, seen in connection with the coal formation and a number of others, are inexplicable by the theory of transportation. We have therefore to come to the second hypothesis, and to see whether coal beds proceed, like the peat beds of our time, from the growth of vegetables the debris of which have been yearly and successively heaped in place and then transformed into coal. This is called the peat-bog theory.—The formation of peat is generally little known or understood. Few works have been published on the subject, and as the bogs are generally of difficult and even of dangerous access, they are rarely examined carefully enough to obtain full evidence as to the details of their formation. And furthermore, this study demands a knowledge of botany and chemistry rarely attainable by the student before the years of his strength for field explorations are passed. Peat is formed in shallow water or in bogs, by the growth of

plants which may be called bog plants, and which belong to a peculiar group of vegetables composed essentially of woody tissue and living either in water or above water, according to local circumstances. The species of plants forming peat in our time do not thrive out of the bogs, neither do land plants invade the bogs and contribute by their remains to the composition of peat. The bog plants demand first, for their establishment and their growth, a shallow basin of water with an invariable level. A basin of this kind is generally prepared in advance by the deposition of a clay bottom, produced from the decomposition of water plants or plants living entirely under water, whose tissue from this cause is not woody or fibrous; for the woody tissue of the plants is derived from the atmosphere, chiefly by the respiration of the leaves, and constitutes a part of the compound generally proportionate to the degree of humidity and the amount of carbonic acid of the atmosphere wherein they live. The conferves and the charas which fix lime or silex in their tissue and feed fresh-water mollusks, sometimes in immense number, are especially the plants which by decomposition form a kind of clay. In some circumstances this vegetation has, by its remains and those of the shells, established a thickness of muddy clay of 2 to 6 in. in a year. When this bed of clay has rendered the basin water-tight, it becomes a prepared ground for the growth of other plants, which, rooting in the soft bottom, ascend upon long stems or long stalks to the surface, where they expand their leaves and open their flowers. These are at the same time aerial and water plants; their tissue is woody like that of some species of mosses, which appear at the same time, and floating at the surface absorb carbonic acid and water by their innumerable small leaves, and thus have in their compounds as large a proportion of woody matter as the hardest wood. Every year the remains of this vegetation are pressed down to the bottom, and successively heaped till they reach the surface of the water. Of course this first deposit becomes in time solid enough to receive other kinds of plants which root upon its surface: species of mosses, sedges, and trailing bushes; then larger shrubs, then trees, which, with the smaller species that continue to grow under them, increase each year by their debris the amount of material which, constantly heaped, constitutes what is improperly called the growth of the peat. This is the simplest and most ordinary proceeding in the formation of peat. The process of transformation of vegetable matter into peat is due to the presence of water, as is apparent from a consideration of the different modes of decomposition of vegetable matter as explained by chemistry. When wood is immersed in water and thus guarded against the action of the atmosphere or of the carbonic acid which causes its decay, it is preserved sound for a very long time. Roman construc-

tions, even foundations of the lacustrine buildings of wood, have been dug out still solid and unimpaired by decay from lakes and swamps of Europe; but the wood has become entirely black. When the materials which enter into the composition of peat are growing in a deep basin of water, and their debris are heaped under water, the preservation of the matter against rapid decomposition is then the direct result of immersion. The growth of the peat in cases of this kind may be stopped at the water level, where by a more complete decomposition of the plants a coat of humus is formed, which being invaded by land plants is transformed into a prairie or a forest.—But more generally peat grows above the water level, and then the production of the matter and its protection against the influence of the atmosphere are essentially due to the agency of a peculiar kind of moss, the *sphagnum*. This moss, which in deep water vegetates in loose extensive matings, extending over the surface like a vegetable carpet, becomes out of water transformed into compact tufts, and its long slender stems, then growing closely pressed against one another, are knit together. The sphagnum is in that state a veritable sponge, endowed with an extraordinary power of absorption. Not only does it draw the water from below by its long capillary stems, which, growing without interruption, are imbedded very deeply in the matter of the bog, but it especially imbibes it from atmospheric humidity by its innumerable small leaves, and thus is constantly saturated with water. Its growth is rapid; where more space is afforded, it extends its plants all around, covering the whole surface of the bogs and every kind of woody debris spread upon it. Its tufts go up the roots of the trees, and surround the standing trunks one to two feet high; they pass over the prostrate trees and their branches, and bury them under a thick carpet which preserves them against atmospheric influence. In foggy countries, as in Ireland and Germany, the sphagnum ascends steep slopes and builds its peat deposits from the plains to the tops of high mountains. This moss is indeed by itself a remarkable phenomenon in the economy of nature; being a kind of balancing power, absorbing the useless surplus of water from the ground, from the swamps, and from the atmosphere especially, using it in part for its growth, carefully husbanding it for the preservation and transformation of all the woody tissue, its own included, into peat, and in dry seasons distributing the remainder to feed the numerous springs which have their source in the bogs. Thus, the peat bogs, like the glaciers of some countries, feed mighty rivers. In the Mississippi, for example, the blackness of the water, which is preserved as far down as St. Louis, proves its origin. It is nothing but bog water; hence its extreme salubrity and its remarkable incorruptibility.—Along the low shores of some lakes and of the sea, the bog vegetation sometimes begins from

a sandy bottom without an intermediate clay bed. This happens especially when shallow basins of water are closed by sand deposits, and thus totally separated and guarded against the invasion of outside water and the muddy materials which might be brought upon it. These basins have a permanent level, and thus the work may proceed without interruption. The peat formed in that way rests immediately upon a bottom of sand, as coal beds are found sometimes also upon sandstone. It happens, however, that in some deeper part of the same basins the subaquatic vegetation is established, and its decomposition forms beds of clay or a clay bottom whereupon the old coal plants take root at a later period. The same bed may therefore at different places rest upon clay or upon sand. This fact also is remarked in coal beds of some extent whose bottom is at intervals either clay or sandstone. It also frequently happens, especially in small lakes and bayous, that the peat vegetation begins at the surface with floating masses, which gradually invade the whole space, covering it with a vegetable carpet. By successive annual growth and deposits this groundwork becomes thick and more solid; shrubs and even trees take root and grow upon it, till the mass becomes too heavy, is split or torn asunder, and sinks to the bottom. Other series of vegetation may begin again in the same way and be successively heaped upon one another, peat beds and forests, till the basins are filled. From some of these filled lakes now discovered under thick strata of humus, peat and wood, and even large trees which could be used for building, have been dug out to a thickness or a depth of 75 ft. or more. In New Jersey a considerable business has been done in fishing out of peat bogs the buried cedar timber. At other localities, as in the old bayous at the mouth of the Mississippi, floating islands, strong enough to support the construction of railways, have been formed in the same manner. Their nature is recognized by the vacillation and unsteadiness of the ground, which undulates under the pressure of a heavy weight like that of a railway train. At other places, as in the Dismal swamp, the formation is mixed. A bed of peat 15 ft. thick is formed over the swamps around Drummond lake, by the debris of large trees and of an impenetrable grove of canes, whose roots penetrate deeply into thick layers of sphagnum. It is there extremely difficult to reach the borders of the lake. They are mere floating moors, sinking under the weight and formerly extending over and covering the whole surface of the lake. This is proved by a layer of trees strewn at the bottom of the lake, and the process of nature may be seen still in activity along the borders, where large trees (bald cypress), sunk into the water, perhaps 8 ft. deep, are there slowly decaying in a standing position. Their trunks are already generally hollow, only the bark and a thin crust of wood being left; the water enters them of course, and fills them with

the debris floating upon the surface, especially cones and leaves. In time these decayed trunks fall to the bottom and are there imbedded either for slow decomposition to peat, or if covered with mud petrified by the softening of their tissue and the impregnation of mineral matters. In that way the hollow trunks discovered in the coal beds of England and Canada have been petrified; their bark only is preserved, and they are filled with cones, leaves, insects, shells, &c. These fossil trees were looked upon for a long time as an inexplicable wonder.—Various circumstances, as local depressions which bear water upon the surface of the emerged peat bogs and destroy their vegetation, stop the growth of the peat and change the surface into mud swamps. This is especially caused by alternation of level, or by the ground being covered with water at one time of the year and dry at another. Then the decomposition of the plants is rapid and entire, and its result is a kind of mud increased by the introduction of foreign materials brought by water. Leaves and vegetable debris are often imbedded in this matter and thus preserved by petrification. This represents the formation of the laminated clay shale which generally covers the coal beds as a roof, and contains in some localities vegetable remains in a beautiful state of preservation. Of course, these changes of level were formerly, especially at the carboniferous period, more frequent than now; for then the land was mostly of insecure formation, half floating, and along the sea immense tracts of land were engulfed, and so deeply sunk that their surface was covered with sand by the currents, or even at a greater depth invaded by the animals building and forming limestone deposits, shells, madrepores, corals, &c. In this way the formation of the sandstone and limestone which in some places overlie the coal beds without intermediate shale is easily understood. Cases of a similar nature are recorded from the peat bogs of our time. It has been said already that in Holland old peat bogs have been discovered by borings, at a depth of from 60 to 100 ft. below the surface, placed upon one another and separated by clay deposits of 30 ft. or more. The great peat bogs between the lakes along the foot of the Jura mountains in Switzerland sink in places under the sands of the lakes and are covered by gravel. At other localities the peat deposits of a thickness of 10 ft. are cut in the middle by a layer of coarse sand varying from 6 to 12 in. in thickness. We see therefore in the present formation of the peat bogs a counterpart of that of the coal, represented in all its details, though in a reduced proportion. Not a single case has been recorded in regard to the formation of coal which cannot find its counterpart and its explanation in some of the phenomena attending the present formation of peat. In the countries where peat banks are exposed and worked to their base by drainage, and where the nature

and distribution of their materials can be studied upon the exposed face of the beds, these compounds are seen constantly and extremely variable: heaped remains of woods, of mosses, sometimes whole forests prostrated and imbedded. But in these beds the alternation of the annual layers is always easily recognized. Near the top their thickness is generally more than an inch; near the base they become by maceration and compression reduced to one sixth of an inch or less. In the oldest peat bogs, the lower layers are formed of a soft pellucid matter resembling a black glue, alternating with a more opaque and fibrous material, thus exactly corresponding in their appearance to the pellucid and opaque laminae of the coal. Hardness or induration of this old peat seems to the eye the only process needed to transform it into coal. The submerged peat, that of the lakes or of the seashores, frequently and extensively formed in Holland, North Germany, and elsewhere, is not laminated; the matter is generally compact, homogeneous in aspect, and nearly reduced to paste, at least in its more advanced stage of decomposition. The difference is caused, as remarked already, by the semi-aquatic nature of the plants which enter into its composition, and which, being less fibrous than those growing upon emerged bogs, are more easily and equally transformed under water. This process explains the difference between the laminated bituminous coal and the compact homogeneous cannel. The immense trunks mixed in the beds of laminated coal evidently prove that some of the beds were formed above water. On the contrary, cannel coal, whose compounds, so far as they can be recognized as vegetable remains, are essentially the floating trunks and branches of *stigmara*, indicates as evidently that in this case the coal was formed of plants floating or submerged, thus presenting the two essential differences which are recognized in the peat beds of our time. Local variations in the phenomena attending the formation of immersed peat are quite as frequent and remarkable as in the formation of the emerged peat bogs. It would require a volume to describe them in detail. Near Kiögge in Denmark, along the seashore, extensive peat deposits now covered by a layer of humus forming prairies are composed merely of birch trees, whose bark is separated from the decomposed woody matter; this is a semi-fluid brown paste at the bottom, 4 to 6 ft. thick, and the bark at the surface forms a layer of hollow cylinders or compressed sheets without any woody matter between them. The exploitation of these deposits is made to get the woody paste, which is taken in buckets from under the layer of bark, spread upon beds of straw, and when somewhat hardened by the percolation of water is kneaded, flattened, and pressed with shovels, and then cut and dried, thus forming a very valuable fuel. The bark is left out of

the trenches as of little value. We have in this case the illustration of a peculiar formation of some beds of coal whose top is overlaid by a stratum mostly composed of pieces of bark of *lepidodendron*, *sigillaria*, *calamites*, &c., pressed upon one another without even laminae of coal between the layers. At Trevorton in Pennsylvania, a bed of semi-anthracite thrown up to the perpendicular is roofed by such a layer of petrified bark, and exposed like a wall of mosaic work, diversified by the impressions which mark the surface of the bark of most of the species of trees of the carboniferous period.—It has been objected to this theory of the production of coal, that the peat beds, however thick they may be, could not account for the immense mass of combustible minerals or of woody matter contained in a coal bed even of moderate thickness. This is a great mistake, for indeed nothing but the growth of the materials upon the place where they have been buried and transformed into coal can satisfactorily account for the immense proportion of woody matter in the deposits. The comparative caloric power of wood, peat, and coal has been found to be on an average represented by the proportion of 30 for wood, 37 to 40 for peat, according to its age, and 60 for bituminous coal. We have seen above what is the average production of wood under the best regulated cultivation of Europe. The growth of peat, as recognized from repeated observations, also made in Europe, averages one inch a year at the surface. By compression and decomposition the matter is reduced toward the base of the banks to one sixth or even one eighth of the original thickness. Comparing this production with that of the wood of a forest upon an equal area and in the same period of time, we see from the same records quoted above that the peat yields in cubic feet, after desiccation, twice as much combustible matter as the forest. Peat bogs are now, especially in wet countries, as in Ireland, Sweden, and Russia, not only of wide extent but of great thickness. In Switzerland and Germany the average thickness of peat beds is 8 to 12 ft.; but in the same countries the peat attains in some localities a thickness of 30 ft. in continuous and extensive beds. In Ireland, Denmark, and other northern countries, there are beds of combustibles formed of peat alternating with prostrated forests, from 60 to 80 ft. thick or more. Now, a bed of peat 30 ft. thick, comparing its matter with coal according to the proportion of 40 to 60 for caloric produced, and deducting one half for drying the matter and rendering it fit for fuel, would represent an amount of woody matter equal to that of a bed of coal 10 ft. thick. It is therefore conceivable that at the carboniferous period, when the atmosphere was saturated with vapors and carbonic acid gas, the essential elements which feed the plants and supply woody tissue, the luxuriance of the vegetation must have been far above that of our time. The heaping of

the vegetable remains must then have attained in favorable localities a thickness at least double that of the present peat deposits. The supposition that the plants at the carboniferous epoch contained more bitumen than those of our time has no foundation whatever, as bitumen is obtained from peat in as large proportion as from coal. Mineral oil, which also results, in its essential part at least, from the decomposition of vegetable matter, is in this particular only comparable to coal; but it is produced from marine plants which have no fibrous tissue, but merely cellular matter.—After reading the foregoing descriptions of the growth of peat, the admirable simplicity of the process used by nature to reach its end in providing deposits of combustible minerals in the several geological periods is evident enough. This identity, however, can be still more positively proved by comparing the chemical operations attending these formations, and the absolute similarity of the elements which compose the different matters known under the names of peat, lignite, coal, and anthracite. The composition of these combustible materials, as they are generally called, compared with that of wood and of woody plants which by their characters and texture are related to the most common species of the coal measures, and which enter into the composition of peat in our time, is presented in the following table compiled from Dana's "Manual:—"

SUBSTANCES.	Carbon.	Hydrogen.	Oxygen.
Wood.....	49·66	6·21	43·08
<i>Lycopodium dendroideum</i> ...	48·70	6·61	43·25
<i>Lycopodium complanatum</i> ..	48·43	6·61	43·02
<i>Equisetum hyemale</i>	47·50	6·68	44·49
<i>Sphagnum</i>	49·88	6·54	42·42
Peat.....	59·5	5·5	38·0
Brown coal or lignite.....	68·7	5·5	25·0
Bituminous coal.....	81·2	5·5	12·5
Anthracite.....	95·0	2·5	2·5

This table shows in *lycopodium* species and *equisetum* about the same composition as in wood. These correspond in structure, and have at the same time a generic relation to the species forming the essential compounds of coal as recognized by microscopical examination, viz.: *lepidodendron*, *sigillaria*, and *calamites*. The *sphagnum*, which enters more than any other plant into the composition of peat, has more carbon than lycopods, even slightly more than wood. In the decomposition of the woody matter two different processes are recognized by chemistry. Decayed wood taken from the interior of trunks of dead trees exposed to atmospheric action gives by analysis, on the average, carbon 47·62, hydrogen 6·18, oxygen 44·87; which compared with wood, C. 49·66, H. 6·21, O. 43·03, indicates that through this decomposition a proportion of carbon has been taken from the wood, while the hydrogen is slightly increased. The elements of water therefore, and an amount of oxygen, have become united with the wood, while carbonic

acid has been separated from it. This comparison of analyses exemplifies the well known fact that the decomposition of plants under atmospheric influences returns to the atmosphere the carbonic acid absorbed by the vegetation, which by nutrition of the living plants is transformed into wood. But when the woody matter is protected against the action of the oxygen of the air, as it is in vegetable remains under water or covered by mosses impregnated with water, the chemical changes as proved by analyses assume another form. This is the case in the formation of peat, which when ripe has C. 59·5, H. 5·5, O. 33, or compared with wood an increased amount of carbon in proportion with a diminution of oxygen, separated into carbonic acid with a little of the hydrogen of the wood. The amount of carbon in peat, as in all the mineral combustibles, is extremely variable; in young sphagnum peat it is no more than 51 to 52 per cent., while in old peat it is as high as 61 to 62 per cent. The proportion of bitumen increases in peat in the same degree. Taken from old beds, this matter has yielded by distillation 30 per cent. of bitumen. To obtain it, the distillation of peat has been practised for many years on the bogs of the Jura in Switzerland; and peat from the bogs of Ireland is also distilled in large establishments for manufacturing candles. This sufficiently answers the objection made against the theory of the formation of coal from heaped vegetables by annual growth like beds of peat, and the mistaken assertion that peat has no bitumen and therefore cannot form coal. The composition of peat as given above does not differ much from that of the more recent lignite of Germany, showing therefore the same process of chemical action. These lignite beds, mentioned before, are heaps of trunks overlaid by thick strata of sand and clay. The wood is black and quite soft, but its texture is still as well preserved and as distinct as in living trees. The matter in its purity has C. 57·28, H. 6·03, O. 36·10, or a less amount of carbon than old peat, with more oxygen; thus proving that the process of decomposition is exactly the same, but that it is in a less advanced stage. In lignite of an older formation the analysis indicates C. 68·7, H. 5·5, O. 25; therefore an increase of carbon, still resulting from the same combination, the diminution of the oxygen and of a little of the hydrogen of wood. As in peat, the amount of carbon in lignite is very variable, which results especially from the nature of the original compounds. The lignite of the old tertiary of the Rocky mountains, which in many beds has the same appearance, lamination, and nearly the density of the true coal, has only 51 per cent. of carbon in an average taken from the comparison of 21 analyses of the matter from many localities. This reduced amount of carbon is apparently due to the great proportion of palm wood and palm remains which entered originally into its composition. The average composition of the best quali-

ties of bituminous coal is C. 81.2, H. 5.5, O. 12.05; showing still the same proportion in the diminution of the oxygen and the increase of carbon. The chemical action is therefore constantly the same, and is recognized in the whole process; that is, the slow combustion of the woody matter by the action of the oxygen which it contains, or contained originally. Chemistry has not perfectly explained the process, or obtained similar results and products by its experiments. Prof. Dana says that the changes attending the ultimate decomposition of woody matter into coal depend: 1, on the affinity of the carbon for oxygen, making carbonic acid; 2, on that of hydrogen for oxygen, producing water; 3, on that of carbon for hydrogen, making carbo-hydrogen gas or oil; and 4, on the tendency of the carbon and the hydrogen under certain proportions to form with a portion of oxygen the staple compounds included in the term coal. In anthracite the amount of carbon is still increased, while that of hydrogen and oxygen has become proportionally less, and the volatile matter is reduced to a minimum. Hence pure anthracite is debiturized and burns without any flame. The anthracite of Pennsylvania becomes harder and more free from gas in proportion to the distance of the basins eastward from the Alleghany mountains, where its beds are folded in more numerous and sharper flexures. It has been supposed that its debiturization had taken place from some cause connected with the uplifting of the mountains. The first supposition was that the coal had been reduced to anthracite by heat. This opinion has been contradicted by another hypothesis which ascribes the transformation to great compression of the mineral coal by the upheaval of the mountains between whose sides the basins were slowly pressed, and thus slowly forced into numerous folds, and perhaps to a considerable amount of caloric produced by mechanical agency, movement, compression, &c. Many facts seem to contradict this last hypothesis, and support the opinion that the original heat of the earth has contributed to the metamorphism of the coal, as it has to that of the rocks. The problem is however complex, and cannot be discussed in a few words. The facts have to be recorded, and the conclusions may become evident in time. In Pennsylvania the debiturization decreases in proportion to the distance eastward from the mountains. At Trevorton, in Zerbe's gap, the coal is semi-anthracite; it has 84 to 86 per cent. of carbon, 7.50 of inflammable gas, and 2.50 of water. Though this basin is far distant from the mountains, the undulations of its beds are nearly as sharp as those near Pottsville and Tamaqua, being inclined at an angle of 50° to 60°. As the thickness of the strata is great, the pressure seems to have been equal to that nearer the mountains. In the Rhode Island basin the anthracite is still harder and more debiturized. Here the undulations are repeated, very

numerous, and short, but not sharp, resembling the waves of the sea, and the strata are not thick; but the anthracite is in close proximity to the primitive rocks, and the shales over and under the coal show by their color and density the evident traces of metamorphism. There is here a peculiar phenomenon marking the influence of heat; it is the liquefaction of the shale and the effects of it on the vegetable remains, particularly the ferns. Their branches are generally elongated in one direction and contracted in the other side, as though drawn to one direction by the flexure of the shales in a state of semi-fusion. The plants too bear upon their surface a kind of intumescence, seemingly produced by heat. At Trevorton the shales over the coal are more or less marked by small round holes varied in size, filled with a pulverulent bituminous matter which looks as if formed by a kind of ebullition, or rather by gas forcing its way from the anthracite and stopped and enclosed within the shale. In Arkansas the Spadra coal is semi-anthracite. The strata wherein it is interlaid are nearly horizontal, their dip scarcely marked by an angle of 2°. It is also at a distance of 30 m. from the mountains. It has about the same composition as the Trevorton coal, 88.75 per cent. of carbon, with 7.7 of volatile matter. The rocks all around in the country bear traces of metamorphism, and the change by heat becomes more and more evident in advancing toward the Hot Springs, a volcanic region, away from the mountains. The same phenomenon is still more evident, and its cause more appreciable, in the tertiary lignite basins of the Rocky mountains. At Golden, Colorado, the thick lignite beds, 12 to 16 ft., are thrown up to the perpendicular by compression, in close proximity to the base of the uplifted granitic mountains, and between them and thick deposits of lava. This coal is soft, bears no trace of metamorphism, and even crumbles from the contact of the atmosphere. In New Mexico the strata are horizontal, but split by thin dikes of basalt, along which the coal shale is changed by heat and nearly as hard as silex. The nature of the coal in contact with these dikes has been recorded from a locality further south, near the valley of the Gallisteo, where the Placiere coal at one exposure of the bank is true lignite, while at another exposure, and in contact with an enormous dike of basalt, it has been changed into true anthracite, having 89 per cent. of carbon and only 3.18 of volatile matter, while at a distance from the dike the amount of carbon is only 58 per cent. The dip of the strata even in coming closely in contact with the dikes varies between 10° and 14° only. These facts are evident proofs of the debiturization of the coal and its change to anthracite by the action of heat. In this we have at the same time an insight into the chemical changes causing the modification of vegetable matter and its transformation into coal. For the action of heat does not deprive the coal of any part

of its constituents ; it merely quickens the slow burning or metamorphosis of the matter, the ultimate result of which is the entire reduction of the oxygen- and hydrogen-producing volatile gas into compact or condensed mineral combustible, a mere compound of the original elements of wood modified under peculiar influences.—The great Alleghany coal field extends from the middle of Alabama to northern Pennsylvania, and occupies portions of Alabama, Georgia, Tennessee, Kentucky, West Virginia, Virginia, Ohio, and Pennsylvania. It contains from 50,000 to 55,000 sq. m. of coal area, and all the coal beds and groups of beds described under the title *ΑΝΤΗΡΑCΙΤΕ*, the nomenclature of which will be adopted herein. In some portions of the anthracite fields the millstone grit or conglomerate is interstratified from the bottom to the top of the coal measures, though much more massive near the bottom than in any other portion. It is also much thicker in the eastern part of these fields than in the western portion, and likewise more massive than in the bituminous fields, or westward generally, as the foregoing table indicates. A group of coal beds, O, not shown in the anthracite column, though existing there as “nests” of imperfect coal below A, are found

A, or Alpha

at irregular intervals throughout the Alleghany coal field ; but these beds are thin, impure, often absent, and rarely of workable size or merchantable quality. They exist both below and in the millstone grit when found, and are more persistent and regular in the western than in the eastern coal fields. The first group of regular beds is A ; these also exist in the conglomerate in the Pennsylvania anthracite fields, and in some of the outlying basins of the Alleghany field ; but generally they consist of two small, unworkable streaks of impure coal, or a single bed of earthy coal 1 to 4 ft. in thickness, resting on or near the millstone grit. It produces the block or furnace coal of Pennsylvania.

B, or Buck Mountain.

The next group, B, consists of two regular and excellent beds, which are generally united as a single bed, though always divided by a streak of slate or fire clay, which often expands to 20 ft. or more. This bed, or group of beds, is the most regular of all the American coal beds ; and, being the first large, workable, and productive bed, its horizon is the most extensive, and nearly equal to the area of the entire field, while it can readily be identified in the central if not the western coal field. These beds, when united, are from 4 to 7 ft. thick, and singly from 2 to 4 ft. each. Immediately above this group, sometimes resting on the coal, but

generally separated by slates and shales, is the micaceous sandstone, or “buckwheat rock” of the Pennsylvania mines, which is a coarse, massive sandstone, filled with mica scales. This rock is very persistent, and can be identified in all the great American coal fields of the carboniferous age. This great bed of sandstone, which is often 20 to 60 ft. in thickness, is followed by shales and the fossiliferous or ferriferous limestone, and the buhr-

C, or Gamma.

stone iron ore, which are generally present in the Alleghany coal measures. The ore ranges from 10 to 20 in., and the limestone from 10 to 20 ft. in thickness. This is succeeded by shales and the group of coal beds C. In the anthracite regions, and generally in the bituminous fields, this group consists of two thin, slaty, and unworkable beds ; but one of them frequently expands to 3 and even 5 ft. of excellent splint or cannel coal. It is the celebrated Peytona cannel bed of Coal river, West Virginia, and the Grayson cannel of Kentucky. This group is succeeded by shales and sandstones of variable thickness, from 50 to 150 ft., on which rests the bed D, which is always single, and generally pure and workable, from 30 in. to 4 ft. in thickness. Above this bed, separated by sandstones and shales, is the Curlew or Freeport limestone, 8 ft. thick ; and on or near this rests the group E, which embraces two or three beds of coal, each generally from 2 to 4 ft. thick, which often unite as a single bed of 6 to 12 ft., divided by slates. This group forms the celebrated mammoth bed in the Pennsylvania anthracite fields, and the Freeport beds in the western part of Pennsylvania. Above this group (which is very confusing to the miner and the geologist, on account of its irregularity and uncertainty in uniting and dividing) from 20 to 50 ft. of soft black shales or slate are generally found, and on these rests the Mahoning or mammoth sandstone, which is the largest regular sand rock in the Alleghany coal measures, ranging from 50 to 75 ft. in thickness, divided by one and sometimes two thin coal seams, and several feet of slates or shales. Streaks of quartz crystals are often found between the upper and lower strata of

D, or Skidmore.

E, or Mammoth.

this great rock, which is a quartzite, and often a conglomerate rock, 80 ft. thick in the anthracite measures. It is sometimes accompanied by a stratum of white quartz secretions,

F, or Holmes

or conglomerate, even in the western portions of the field, which are often mistaken for water-worn pebbles. This is a great landmark in the Appalachian coal fields, which cannot well be mistaken, and yet it is often misplaced. Above this exists the group F, which consists of two thin impure beds, divided by a few inches of fire clay, known as the rough

bed in the anthracite fields, where it is 5 to 7 ft. thick, and as a single bed in the Alleghany field, 1 to 2 ft. thick of slaty and sometimes 3 ft. of cannel coal. It seems to be a true horizon of coal, but is seldom found in merchantable quantity or quality. Above these are from 200 to 300 ft. of shales, slates, sandstones, and limestones, followed by the bed G, which is the large and celebrated Pittsburgh bed, remarkable for its production of excellent gas, coking, steam, and household coal, combining all the qualities of every variety of bituminous coal except the block and cannel. It ranges from 6 to 12 ft. in thickness, averaging from

G, or Primrose.

6 to 8. Between these great beds, E and G, exist from 300 to 450 ft. of unproductive strata, which contain no workable beds of coal. These are known in Pennsylvanian nomenclature as the lower barren measures, which are as distinctly marked in the anthracite as in the bituminous fields of this state. It may be briefly stated that all the coal beds and coal measures existing in the anthracite fields above G are found in some portions of the Alleghany field; but the coal beds are thin, rarely workable, and cannot be identified. From 1,000 to 2,000 ft. of coal measures are supposed to exist above G; but these are known as the upper barren measures, and are made up chiefly of shales, with a few coarse sandstones and massive limestones, one of which is 70 ft. in thickness, and is distinctly defined over a large area. The general average thickness of the coal measures between B and G is 1,000 ft., but varies from 500 to 1,200 ft. From the carboniferous limestone to B, including the groups O and A, the thickness of the strata is from 200 to 500 ft., and the total thickness of the coal measures about 3,000 ft. in Pennsylvania, with a minimum thickness of 30 ft. and a maximum of 50 ft. of coal.—The distribution of the deposits of coal in North America is well adapted for the supply of the wants of the present inhabitants. The largest population is along the Atlantic

coast, and the best coal, that of the anthracite fields of Pennsylvania happens to be situated nearer the largest markets than any other, being less than 200 m. from New York and less than 100 m. from Philadelphia. The basins producing it are small, containing in all but 470 sq. m.; but the beds are very large and numerous, and the quantity produced is about half of all the coal mined in the United States. (See ANTHRACITE, LACKAWANNA, and WYOMING VALLEY.) In the eastern central part of Pennsylvania, where the anthracite basins are situated, great disturbances of the strata have taken place after they were deposited, caused by the gradual upheaval or subsidence of alternate portions in N. E. and S. W. lines, so as to throw them into a waving form. This disturbance was greatest toward the S. E., and the rock arches become wider and flatter as we go N. W.; but they extend S. W. entirely across this state and Maryland, and their effects are even seen in the coal field of eastern Ohio. All anthracite coal is found in regions where the strata have been considerably disturbed, or where from local causes it has been subjected to heat. Next westward from the anthracite in Pennsylvania the coal is semi-bituminous, and still further west it is of the ordinary bituminous character, the quantity of volatile matter constantly increasing toward the central part of the field. The carboniferous formation terminates in the northern part of Pennsylvania, and the division into counties of that district happens to correspond with six of the great flexures of the strata before mentioned, which give rise to six coal basins. Some of these from their far northern position contain some of the richest and most productive mines in the state. They produce, for the supply of the coalless country north of them, the variety commonly called Blossburg, which is used for steam and manufacturing purposes. The deposits of coal extend in this northern district along the middle or bottom of the basins only, in lines of small detached fields or chains of basins, which are more extensive as they are followed S. W. until they become uninterrupted prongs or finger points. Still further S. W. in Pennsylvania the lower beds arch over portions of the intermediate anticlinals, and in the S. W. part of the state, in the Pittsburgh country, the four or five lower beds which alone occur further N. disappear on the surface, dipping under a red and gray shale formation in which are no coal seams. Above these barren measures in the highest ground about Pittsburgh appears another bed of excellent coal, named after that city, from which all the coal is mined that is used in the S. W. part of the state, large quantities of it being also sent down the Ohio and Mississippi rivers. Pennsylvania not only supplies the United States with all the popular fuel anthracite, but she also produces more bituminous coal than any other state, of which she

has every variety of excellent qualities. The northern districts in 1873 produced 1,500,000 tons, and the eastern margin of the field

FIG. 5.—Appalachian Formations, Ancient and Modern.

EXPLANATION: *Modern*.—*a*, the Atlantic sea; *b*, recent or cretaceous formations; *c*, granitic and volcanic; *d*, mesozoic, new red, &c.; *e*, metamorphic, gneissic, &c.; *f*, sandstones and limestones of the valley or the lower palaeozoic formations; *h*, slates and shales of the oil-producing formations; *i*, sandstones overlying the oil strata, including the old red and the conglomerate; *j*, the anthracite coal deposits; *k*, Cumberland coal field; *l, l', a*, Allegheny coal field; *m*, Ohio river.

The Potsdam sandstone underlies the Aurora limestone, *g*, and overlies the gneiss, *e*, which must exist to some extent in the entire basin. The dark vertical trap formations emerge from the granite, and were the means of forming the gneiss.

Ancient.—No. 1 corresponds to *a*, and is the granite seacoast line, forming the volcanic boundary of the ancient sea; 2 is a deep view of the volcanic vent between the granite and the gneiss, which is formed of the vented matter; 3 is the metamorphic or early gneissic sedimentary rocks; 4 corresponds to *g*, and is the base of the palaeozoic; 5 is the bituminous slates of the oil strata, followed by the massive sandstones of the old red, and the subcarboniferous; 6 is the ancient sea, since filled by the sedimentary deposits represented in *g, h, i, j, k, l, &c.*; 7, 7' is the line of volcanic vents existing in the plutonic or granite coast line, which extends from Maine to Cuba. The form of the ancient structure is of course ideal, and the two views are thus given together in order to convey an impression of the cause and its effects.

1,000,000 tons of semi-bituminous coal. Of the common bituminous coal 9,000,000 tons were mined in that year, chiefly in the Westmoreland and Pittsburgh districts and along the Monongahela and Youghiogheny rivers, for the supply of all the western states by way of the Ohio and Mississippi rivers, for gas making in the eastern cities, and for domestic and manufacturing purposes in the state. This is therefore the greatest of all the coal-producing states; and from its geographical position, its rich endowment of other minerals, and other natural advantages, there is every probability of its continuing to retain this position for a long time. The coal field which covers the eastern part of Ohio is the western border of that of western Pennsylvania. It stretches along the Ohio river from the Mahoning river on the north to near the Scioto on the south, from two to four counties in width, embracing 10,000 sq. m., being nearly as large as that of Pennsylvania, which has 12,774 sq. m. of coal. Along the N. E. border is found a peculiar splint or block coal, which has been used for many years in its raw state in blast furnaces; some small basins of it also occur on the Pennsylvania side of the line. Further south, in the Hocking valley, occurs a coal bed of extraordinary size, measuring in some localities 12 ft. in thickness, and it is said that it can also be used like the block coal. The production of coal has not been very large in Ohio (about 4,000,000 tons), but from the building of railroads, and the increase of population and manufacturing, the coal trade of the state is rapidly increasing. Maryland has a very small but very valuable basin of bituminous coal near the Baltimore and Ohio railroad, extending from near Cumberland to Piedmont in the western angle of the state. The production in 1873 was 2,674,110 tons, and since the opening of trade in 1842 the total production has been 24,027,786 tons. It is sold chiefly at New York for the use of ocean steamers and other steam purposes, is known as Cumberland coal, and is semi-bituminous; the bed is 14 ft. thick. West Virginia is almost wholly underlaid with bituminous coal, forming a portion of the same field above described in Pennsylvania, Ohio, and Maryland. The upper coal measures, including the Pittsburgh bed, extend over a large space in the N. W. part of the field in this state, along the Ohio river, as far south as the mouth of the Guyandotte. In the northern part of the state these upper coal beds are developed of good size and quality along the Baltimore and Ohio railroad and on the river about Wheeling. There are very fine natural exposures of the lower coal measures on the Kanawha river, from the great falls to Charlestown. The display of coal in this district is very remarkable, and it has recently been made accessible by the completion of the Chesapeake and Ohio railroad. There are other very extensive districts in West Virginia, both N. and S. of the

Kanawha, where there is known to be a great abundance of excellent coal in localities to which no railroads have been built. There is little or no doubt of the identity of the coal beds throughout the states of Pennsylvania, Ohio, Maryland, West Virginia, and eastern Kentucky, which shows a wonderful sameness in distribution throughout all this vast territory. This coal field extends over the eastern part of Kentucky, and in the northern part of it in this state the Ohio and West Virginia coal beds of the lower series are found, but in the southern counties of the field only the subconglomerate coal beds appear. Very little development has taken place in this district, except on the Ohio river. Tennessee has an interesting and valuable coal field, which is coextensive with the table land of the Cumberland mountain, forming the western boundary of the valley of East Tennessee. In the more northern part of it the lower coal measures of the states further north seem to be found, but the great body of the field is composed of the coal beds still lower in the series which are found in West Virginia and eastern Kentucky. The conditions for coal making appear to have existed in the south earlier than further north; consequently coal is found in rocks which in the north are subcarboniferous and produce no coal. Alabama has the southern extremity of the great coal field we have been describing, divided into three separate portions called the Black Warrior, the Catawba, and the Coosa fields, containing in all 5,330 sq. m. Some of the best deposits of iron ore in America are east of and in the immediate vicinity of the coal fields of Alabama, Tennessee, and West Virginia, which at some future time will make this the seat of large iron manufactures. Thus far, however, but little has been done to bring into use these vast treasures of fuel. This first, Alleghany, or great eastern coal field of the United States, containing in all 58,737 sq. m., is by far the best and in all respects the most important in America.—When the first geological researches were in progress in the western states, it was supposed that the coal beds and the series of coal-bearing rocks were the same in Illinois, Indiana, and western Kentucky as in Pennsylvania, but it is now proved that they are entirely different and never were connected. The recent geological survey of Ohio shows that the great anticlinal axis which passes from Lake Erie past Cincinnati and through the eastern parts of Kentucky and Tennessee is much older than the coal-making age, and that the coal fields of Michigan and Illinois were always separated by it from that of Ohio. The peninsula of Michigan contains a coal field of 6,700 sq. m., extending from Jackson to Saginaw bay, but the coal-bearing rocks are only about 100 ft. thick, and contain but one bed of coal of about 3 ft. or less of coal of a bad quality, full of sulphur and other impurities, and the annual production is small. The ma-

terials of its rocks were derived from the north. The third great coal field covers 6,500 sq. m. in the western part of Indiana, 36,800 sq. m. in Illinois, and 3,888 sq. m. in the western part of Kentucky. The best coal produced in this field is from Indiana, where along the eastern border of it there is a good quality of block coal for furnace use, and some common bituminous coal of fair quality. The Illinois coal is all much inferior to that of Pennsylvania and Ohio, contains a portion of hygrometric moisture which lessens its heating power, and considerable sulphur and other injurious impurities. Notwithstanding this, it is invaluable to the state, which is almost wholly a prairie country, mostly level, destitute of trees, covered in a state of nature with tall coarse grass, and with an extremely fertile soil. The want of fuel of any kind would have been a great disadvantage; and inferior as it is, considerable quantities are annually produced in many parts of the state, especially opposite St. Louis and near other large places. The portion of this field extending into western Kentucky is believed to contain better coal than that of Illinois, and it now produces moderate quantities from mines near the Ohio river.—The fourth great coal field lies west of the Mississippi river, in western Iowa, southeastern Nebraska, northern Missouri, eastern Kansas, the Indian territory, and western Arkansas, and possibly it underlies the cretaceous formation which on the surface separates it from the Texas coal at Fort Belknap; it contains in all nearly 80,000 sq. m. The deterioration westward of the coal continues over this field also, there being fewer and thinner coal beds and coal-bearing rocks, the latter becoming gradually converted into vast beds of limestone, and the shales and sandstones among which coal is usually found becoming subordinate. The best and most productive portion of this field is the district in Iowa along the Des Moines river. In S. W. Iowa and N. W. Missouri, in Nebraska, and the western border of the field in Kansas, the upper coal measures, a great limestone formation very similar to the subcarboniferous limestones below the coal, comes in, containing only one or two very thin beds of coal about one foot thick. The middle coal measures are but little better, the valuable coal beds all being found in the lower coal measures. On the Des Moines river are some beds of fair size, and there is a considerable production. In Missouri, where the lower coal measures are exposed in a district containing 12,420 sq. m., extending from the Iowa line in the N. E. part of the state S. W. across the Missouri river to the Kansas line near Fort Scott, there are workable beds from 2 to 3 ft. thick, and in the absence of better fuel there is local demand for a considerable quantity of the production. This productive coal belt extends into the S. E. corner of Kansas, whereas in the other parts of the state where the coal extends the seams near the

surface are only about one foot thick. The dip of this coal field is toward the northwest, and on its western border Permian fossils are found, this being the only locality where that formation has been found on this continent. —According to the United States census, the statistics of coal production for the year ending June 1, 1870, are as follows: Number of collieries, 1,566; hands employed under ground, 65,000; above ground, 29,854; total, 94,754; capital employed, \$110,008,029; wages paid, \$44,316,491. Bituminous coal mined, 17,199,415 tons; value, \$35,029,247. Anthracite coal mined, 15,664,275 tons; value, \$38,495,745. Total coal mined, 32,863,690 tons; value, \$73,524,992. The distribution of the production of coal in the United States in the following statement from the census of 1870. Except in the case of Pennsylvania, the production is bituminous coal:

STATES AND TERRITORIES.	No. of collieries.	Capital invested.	Tons produced.	Value of product.
Alabama.....	2	\$26,000	11,000	\$39,000
Illinois.....	322	4,283,575	2,624,168	6,097,432
Indiana.....	46	554,442	437,370	938,621
Iowa.....	96	618,332	263,457	874,334
Kansas.....	20	166,430	32,938	114,273
Kentucky.....	30	717,950	150,532	446,792
Maryland.....	22	23,591,600	1,319,324	2,409,208
Michigan.....	3	176,500	28,150	104,200
Missouri.....	56	2,537,250	621,980	2,011,320
Ohio.....	307	5,391,313	2,527,265	5,432,952
Pennsylvania.....	538	67,911,703	23,448,793	52,357,314
Anthracite.....	227	50,322,235	15,650,275	39,422,775
Bituminous.....	361	16,959,418	7,798,518	12,935,039
Tennessee.....	11	313,734	133,413	330,493
Utah.....	6	44,800	5,500	14,350

West Virginia.....	41	1,434,300	603,373	1,035,362
Wyoming.....	1	250,000	50,000	800,000

The total production of coal in the United States in 1873 was as follows:

STATES AND TERRITORIES.	Sq. miles of coal.	Tons.
Pennsylvania.....	12,774	34,523,560
Maryland.....	550	2,674,100
Virginia.....	135	60,000
West Virginia.....	16,000	1,000,000
Ohio.....	10,000	3,944,340
Eastern Kentucky.....	3,933	50,000
Western Kentucky.....	3,838	350,000
Tennessee.....	5,100	400,000
Alabama.....	5,320	60,000
Michigan.....	6,700	50,000
Indiana.....	6,450	1,500,000
Illinois.....	36,800	3,500,000
Iowa.....	18,000	350,000
Missouri.....	23,100	1,000,000
Kansas.....	17,000	50,000
Colorado, Wyoming, Utah, &c.—lignite.....	500,000
Pacific coast—lignite.....	500,000
Total.....	50,512,000

The area of the New Brunswick coal field is very large, but there is only one thin coal bed, too small to work. Nova Scotia produced 411,541 tons of coal in 1873, and Cape Breton island 639,926. The coal is all bituminous and of a

fair quality for gas and steam purposes. There is also an unproductive anthracite coal field in Rhode Island and Massachusetts.—The foregoing fields comprise all the carboniferous coal in North America, and it is not probable that any other districts of any extent containing true coal will hereafter be discovered. Near Richmond, Va., is a very deep coal basin of the triassic age, which was the first worked in the eastern states, and after a long suspension work has lately been resumed. There are two other similar small basins in North Carolina, on Deep and Dan rivers, but neither of them is wrought.—Besides the foregoing carboniferous and triassic coal fields, there is in the N. W. part of this continent a very large area of coal fields which should be described with some detail. The coal or the combustible matter of these western basins is of the kind generally called lignite, of an inferior quality and of a more recent age, the tertiary. It has however the same appearance, and is by its chemical composition true coal; and its distribution in extensive basins along the eastern base of the Rocky mountains, bordering immense treeless plains where no other combustible of any kind can be found, gives to these coal fields an immense value. Indeed, in regard to the population of the gold-mining countries of the Rocky mountains, and to the building of railroads across the plains from the Missouri to the Pacific, the lignitic basin of the west is for the future as important as are for the present the Appalachian coal beds or the coal fields east of the Mississippi river. Along the Missouri river and west of it, the true carboniferous formations sink and disappear under the Permian. The line of the 96th parallel of longitude, from the point where it enters the state of Iowa to the southern limits of Kansas, shows nearly exactly the limits of the old coal fields. Further west the Permian, following a gradual westward dip, is overlaid by the cretaceous formations, which reach a thickness of 2,500 ft. or more; and over these, nearer to the mountains, the tertiary measures appear with their numerous and as yet scarcely explored beds of lignitic coal. By the upheaval of the Rocky mountains, the lower tertiary has been thrown up, sometimes to the perpendicular all along the base of the mountains, and there the capacity of some of its beds of coal has been exposed and is already utilized by workings on a comparatively large scale. The whole lignitic basin may be, like the coal fields of the east, subdivided into different basins, not by any positively marked difference in the nature and composition of the lignitic coal or by any difference whatever in the formation of their coal beds, but merely by geographical limitation, as follows: 1. The New Mexico lignitic basin. It is especially of great extent and rich in coal beds along the Rio Grande, on both sides of it, S. of Santa Fé and Albuquerque as far down as Fort Craig, the supply of fuel for the fort being obtained from

a bed of lignite $5\frac{1}{2}$ ft. thick, 5 m. E. of Don Pedro. A number of other valuable beds have been reported near San Felipe, and still more abundantly northward, around Santa Fé and up to the Raton mountains. The coal of Placiere mountain, which is partly anthracite, is 5 to 6 ft. thick. The following section, taken at the foot of the Raton mountains, shows the average distribution of the lignitic formations of this southern basin:

	Ft. in.		Ft. in.
1. Sandstone and shale, space covered....	60 0	7. Hard sandstone in bank.....	6 0
2. Soft shale and clay.....	35 0	8. Soapstone shale....	2 0
3. Outcrop of lignite showing.....	2 0	9. Lignite, outcrop, good.....	2 0
4. Soft shale and fire clay.....	26 0	10. Fire clay and shale.....	36 0
5. Outcrop of lignite, thin.....	1 0	11. Lignite, exposed....	2 6
6. Hard gray shale with fossil plants.....	80 0	12. Fire clay.....	6 0
		13. Soft shale.....	30 0
		14. Lignite bed opened.	4 0
		15. Ferruginous and shaly sandstone..	50 0

This section rests upon a series of hard coarse sandstone, remarkably mixed with fragments of marine weeds and pieces of bark and of wood, marking this formation as the result of marine deposits along the shores. This, like the alternation of the strata marked upon the above section, especially the deposits of fire clay under each bed of lignite and of shale and shaly sandstone above, gives to the distribution and composition of the lignitic strata an evident likeness to those of the old carboniferous measures. From Trinidad or from the Raton northward to the Spanish peak a number of coal beds have been reported from the same basin as far north as Chicosa, 20 m. from Trinidad. The coal of this country is of a remarkably good quality, some being compact enough to furnish hard coke by distillation, and others producing by the same process a large proportion of illuminating gas. 2. The Colorado lignitic basin, from Pueblo to Cheyenne, covers a wide field, but is to the south at least broken into small isolated areas. One is in the Arkansas valley, E. of Cañon City, with beds of excellent coal, varying from 6 in. to 8 ft. A small basin E. of Colorado Springs has as yet given mere indications of coal in thin beds of 2 to 3 ft. But further north, and from the North fork of Platte river to Cheyenne, the lignitic measures follow the base of the mountains nearly without interruption, furnishing an abundance of fuel to the already large population of the country and to the railroads. Beds of lignite have been opened near the cañon of the South Platte, 5 ft. thick; then in a continuous direction northward, near Green mountain, 7 ft. thick; and at and around Golden, from 4 to 11 and even 14 ft. thick. Five miles N. of Golden, on the Ralston creek, a coal vein is worked averaging 16 ft. in thickness without any parting. Still further N. toward Marshall's a number of beds have been tested varying in thickness from 5 to 9 ft.; and at Marshall's numerous beds have been tested and some worked, varying in thickness from 4 to

11 and 14 ft. Beds of the same kind and of equal thickness are worked still further N. and E. on Boulder creek, Erie, Thomson creek, and Cache la Poudre river. Thus the continuity of the basin appears to be ascertained from the North Platte to near Cheyenne. In width the measures appear to be continuous from the base of the mountains to the Platte, about 15 m. from W. to E. There they pass under more recent formations, and of course may be reached by shafts further E. It is to be remarked, however, that the coal becomes less compact and therefore more subject to disintegration by atmospheric influence, and even liable to spontaneous combustion, in proportion to the distance from the base of the mountains. 3. The lignitic basins along the Union Pacific railroad from Cheyenne to Evanston. On this line the first lignite basin is exposed at and around Carbon. It is of small area, but its beds are thick and the coal of good quality. From Carbon, over lower formations, the railroad passes to a new tertiary and lignitic basin with some thin beds exposed, at Creston, Washakia, &c., and then to a rich productive lignitic region in entering Bitter creek and following it from Black Butte to Rock Spring. At Black Butte three beds of coal are exposed, one of which is worked 8 ft. thick. At Rock Spring an upper coal of excellent quality is worked near the surface, 8 ft. thick, and a lower coal, equally good but only 4 ft. thick, is worked 2 m. E. of the village. A boring made at Rock Spring for the purpose of obtaining fresh water has exposed the remarkable development of the tertiary measures in this country. Below the main coal the record of the boring indicates 41 ft. of lignite in 700 ft. This is about the same amount of coal indicated at Marshall's in a section of about 500 ft. of measures. From Rock Spring to Evanston, a distance of 130 m., an upper tertiary formation, mostly of shale, overlies the lignitic. It has no coal; but some of its beds of shale are so bituminous that in some localities they are worked and used for fuel. Evanston and Coalville are the two last localities where lignite beds have been opened for the use of the Union Pacific railroad. At Evanston the Wyoming coal company works the bed 14 ft. thick, interlaid by three slate partings of a few inches each. The Rocky mountains coal company, adjoining the first, has the same bed of a greater thickness, 43 ft., interlaid with numerous beds of clay and shale. This lignite bed is comparable in its productiveness to the great mammoth bed of the anthracite of Pennsylvania. It however occupies a very limited area. The Coalville beds, at a short distance from Evanston, have been considered by some as identical with the Evanston deposits, and by others as from an older formation, the upper cretaceous. The northern lignitic basin was the first discovered and recorded in the history of the United States. It is however far less known than the others, being as yet out of the lines

of travel and emigration. The so-called lignitic formations were first noticed in Lewis and Clarke's expedition to the Rocky mountains while ascending the Missouri river in 1804. The coal was observed by them at various points from above the Mandan village in ascending the river for a distance of 990 m., and along the Yellowstone river in descending it from about lat. 45° to its mouth, lat. 48° 20'. More recent expeditions in the same country, especially the surveys of Profs. Meek and Hayden, have recorded the same wide extent of area of the N. W. lignitic field and the richness of its coal products. Dr. Hayden in 1857 published a map with sections of the country bordering the Missouri river, accompanied by explanations and documents of the highest scientific interest. This work embodies the results of three years' explorations by the author in the northwest. It marks the outlines of the northern lignitic basin on both sides of the Missouri from below Fort Clark to the Muscleshell river, the northern limit marked by British America and the southern by the head waters of Cherry creek and the Black Hills, narrowing between the Black Hills and the Big Horn mountains, and descending further south to the North fork of the Nebraska river. The author estimates the area of this basin at 400 m. in length and 150 m. in width, or about 60,000 sq. m., which estimate however he rightly considers too low. The most important localities on the Pacific coast where lignitic coal has been produced are Mount Diablo near San Francisco, Coos bay in southern Oregon, Seattle on Puget sound, Bellingham bay in Washington territory, and Vancouver island. It is also found in Alaska and elsewhere, and there is anthracite on Queen Charlotte's island.—Measured by the amount of their annual production, the most important coal fields out of the United States are those of Great Britain, which produce about one half of all the coal mined in

the world. The whole quantity of coal produced in the kingdom since it was first used in the country is estimated at 4,672,090,988 tons, of which the production of the year 1873 was 127,016,747 tons; 86 per cent. of the production of that year was from England, and the anthracite was less than 1,000,000 tons. The quantity of available unmined coal has been ascertained by a royal commission. The resources of coal in the kingdom, amounting to 90,207,000,000 tons in 1871 according to this report, are generally thought to be exaggerated by including the small seams down to one foot in thickness and those below 3,000 ft. in depth, which is probably as deep as coal can be mined, instead of 4,000 ft., as given in the report. The South Wales coal basin has the largest area and much the largest quantity of unmined coal, about 36 per cent. of the whole, but the largest production is from Durham and Northumberland, or the Newcastle coal field. The quantity of coal in Scotland is comparatively small, and in Ireland unimportant. Great Britain exports about 13,000,000 tons annually, and has for many years supplied the world with vast quantities of manufactured articles made with the aid of her coal. The following tabular statements contain much important, useful, and accurate information. The coal produced in 1873 was used and disposed of as follows:

DISPOSITION OF COAL.	Tons.
In the manufacture of iron.....	85,119,709
In steam power in manufactories.....	27,550,000
Domestic or household consumption.....	20,054,000
Exported to foreign countries.....	12,712,222
Used in mines and collieries.....	9,500,000
In the manufacture of gas.....	6,500,000
In steam navigation.....	3,650,000
In glass works, potteries, and brick and lime kilns	3,450,000
On railways.....	3,790,000
In chemical works and all other manufactures..	3,217,229
In smelting other metals.....	763,607
In water works.....	650,000
Total production of Great Britain in 1873....	127,016,767

—France has a large number of small detached coal basins. The basin of St. Étienne, in the department of Loire in S. E. France, has the largest annual production, about 3,500,000 tons; the basin of Valenciennes in the north, an extension into France of the coal field of Belgium, produces nearly as much, and that near Calais almost 3,000,000 tons. These and three or four others in S. E. France, each yielding about 1,000,000 tons per annum, produce the bulk of the coal of that country. The whole production of France in 1872 was 15,899,005 tons, and in 1873 about 17,500,000 tons. The annual production of anthracite is about 1,000,000 tons. The following tables give the most important statistics in regard to them, derived from the report of a late French parliamentary commission in 1874:

KINDS.	No. of concessions.	AREA.		PRODUCTION.	
		Square miles.	Per cent.	Tons in 1872.	Per cent.
Bituminous	819	1,527	52	14,459,273	90.94
Anthracite	146	221	24	1,006,525	6.33
Lignite.....	147	383	24	433,307	2.73
Total.....	612	2,086	100	15,899,005	100

		Bitum.	Anth.	Lignite.	Total.
Worked.....	1,434	204	74	57	335
Not worked.....	652	115	72	90	277
Total.....	2,086	319	146	147	612

Germany is the largest coal-producing country in continental Europe. In 1872 the coal production of the empire was 42,324,466 tons, of which Prussia proper produced 36,973,411 tons; and there was a considerable increase in 1874. Less than one fourth of the whole product, 9,018,048 tons, is lignite or brown coal. The largest production was in the Rhine provinces, 11,500,000 tons; Silesia, 10,500,000; Westphalia, 10,000,000; and Saxony, 9,500,000. About two thirds (6,139,851 tons) of the brown coal comes from Saxony, where also about 3,000,000 tons of true or carboniferous coal is mined. Belgium is the next in rank as a coal-producing country, having mined 15,658,948 tons in 1872; the two principal districts are those of Liège and Hainaut. Austria mined 10,389,952 tons in 1872, more than half of which (5,676,672 tons) was brown coal. Nearly half of the whole product (5,098,080 tons) came from Bohemia, 1,500,000 from Hungary, and nearly as much from Styria. Nearly all the provinces produce both black and brown coal, or carboniferous coal and lignite. Russia has a large coal area, which like that of Scotland is subcarboniferous, or situated geologically below the formation in which the best coal of England and America is found. The only coal field of Russia belonging to the true coal formation is a small tract in Poland containing

80 sq. m., producing one third of the whole amount mined, which was 1,097,832 tons in 1872. Some good anthracite is reported near the sea of Azov, of which 331,896 tons were produced in 1872. Russia also produced in the same year 27,586 tons of lignite and 738,350 tons of bituminous coal. Spain has a good coal field of the carboniferous age, measuring 3,501 sq. m., but the production was only 570,000 tons in 1872. There is also coal in Portugal, the production in 1872 being 18,000 tons. The coal of New South Wales in Australia is believed to be true coal or carboniferous, not a lignite. The amount mined in 1873 was 942,510 tons, but the product does not increase rapidly, as it was 919,522 tons in 1869. The coal in Italy is lignite or later than the carboniferous age, as is also that of India, covering an area of 2,004 sq. m., and those of China, Japan, New Zealand, and South America, except some true coal in Brazil.

—The early history and development of coal is very obscure. It appears to have been used by the ancients only to a limited extent. Theophrastus, in his treatise on stones, mentions *lithanthrax* as used by the smiths of Elis. But the Romans, who excavated several of the ancient aqueducts of France through the coal measures, developing beds of coal, paid no attention to the mineral. The first notice we find in official records of the development of coal in England, the first country in which the mining of coal became a commercial industry, is the receipt of 12 cart loads of "fossil fuel" by the abbey of Peterborough in 850. But evidences exist to prove that coal was used to a very limited extent by the Britons before the Roman invasion; and the discovery of tools and coal cinders near the stations on the Roman wall, indicates that they must have learned its use from the Britons. The first evidence, however, of regular mining operations is found in the books of the bishop of Durham, by whom in 1180 several leases were granted for mining "pit coal," a term since common among the English miners and writers on coal. The coal of Belgium appears to have been developed

about this time, or during the 12th century, near Liège. It is said that a smith named Houillos first used coal in the village of Plénevaux, near that place, about this time, and in commemoration of this discovery the French name of coal is *houille*. Coal was first used in London in 1240; and in 1300 considerable quantities were made use of. A tax of from 1s. to 10s. per chaldron was imposed on coal in England during 400 years, ending in 1803. The first attempt to make pig iron with pit coal appears to have been in 1612, when a patent for this purpose was granted to Simon Sturtevant, but it was unsuccessful. Dudley also obtained patents in 1619 for the same purpose, but also failed, and was imprisoned for debt in consequence. The first successful effort appears to have been made by Mr. Darby of Coalbrookdale in 1713; and in 1747 cast iron suitable for cannon is said to have been made at this place, both the coal and iron ore used being taken from the same mine. In 1700, 64 furnaces were in blast in the forests of England, producing about 20,000 tons of pig iron annually; in 1788, only 13,000 tons of charcoal iron were made, and 61,300 of pit coal or coke iron; but during 1870, 5,963,515 tons were made with coke and coal. The aggregate steam power of Great Britain in 1860 was 38,635,214 horse power, equal to the productive laboring force of 400,000,000 men, or twice the power of the adult working population of the globe. Nothing more striking or instructive, in regard to the value of coal when utilized by an industrial community, could be stated than this fact.

COAL PLANTS. The vegetation of the globe during the different stages of its formation has undergone very great and evident changes. There is however no reason to doubt that the fossil plants known from the different formations of our earth may all be referred to the great classes of the vegetable kingdom distinguished at the present day, viz.: the thallogens, including such plants as lichens, algæ, and fungi; the acrogens, such as ferns and lycopods; the gymnosperms, such as cone-bearing plants and cycads; the endogens, such as palms, lilies, and grasses; and the exogens or dicotyledons, to which belong most of our species of trees. Though the distribution of vegetable fossil remains in these great classes is easily and truly recognized, their relations to genera and species are by no means so certain. What has been said of the formation of coal and its distribution at different geological periods (see COAL) shows that the examination of the coal floras should not be confined to the vegetation of the carboniferous period. But this limitation is admitted here, for the reason that the fossil flora of the carboniferous is more important in its study and is better known than that of any other epoch, and that its essential characters have been recognized

in the contemporaneous floras over the whole world. Moreover, the essential facts concerning the floras of the periods subsequent to the carboniferous measures have been touched upon already.—The plants of the true carboniferous period are mostly, if not all, referable to the class of the acrogens or vascular cryptogams: ferns, lycopods or club mosses, and *equisetaceæ* or the horsetail family. A very few species have been considered as belonging to phænogamous gymnosperms: the conifers by 12 species known only by the structure of fossil trunks which represent them; the *cycadeæ* by so-called species of *Noeggerathia*, all

FIG. 1.—*Flabellaria borassifolia*.

except one, *N. foliosa*, of uncertain relation, and by the very common *flabellaria* or *Cordaites borassifolia*, mostly represented like *Noeggerathia* by long ribbon-like leaves only. One stem of it has been found in a silicified state and analyzed by Corda, who considers the plant as allied by its structure to the lycopodiaceae and to the *cycadeæ*. The true place of these leaves in the vegetable scale is therefore not positively ascertained.—It is a remarkable fact that trunks of conifers, or those referable to this family by their structure, have been found in the upper Devonian and the subcarboniferous measures of the United States, but that as yet no remains of this kind have been discovered in the true coal measures above the millstone grit. A splendid specimen from the upper Devonian of Indiana, a stem half a foot in diameter, has its surface fluted exactly like that of a *calamites*, while its internal structure is related to that of *araucaria*.—The ferns have the most abundant species of the carboniferous period; already more than 600 have been described from this formation. Of these, about 200 species have been found in the coal fields of the United States, more than 50 of which appear to be indigenous or have not till now been observed in Europe. They represent either distinct peculiar types or some analogous ones which are distinguished by less appreciable characters, and which may perhaps be eliminated by comparison with European specimens. As now known, the North American coal flora presents differences evident enough to impress it with a distinct American character, while on the other hand the numerous identical species show it to be as positively representative of the same period as that of the European or other carboniferous floras. The determination of the species of ferns of the coal measures is rendered difficult and somewhat uncertain, at least in regard

to their relation to living species, by the absence of fructifications, which essentially serve

FIG. 2.—1. *Neuropteris hirsuta*. 2. *Adiantites Lindseiformis*.

FIG. 3.—1. *Sphenopteris tridactylitis*. 2. Leaf enlarged.

as characters for their classification. In the fossil specimens, the nervation, which is generally well preserved and distinct, together with

the form of the fronds and of their divisions, the pinnæ and pinnules or leaflets, are the only appreciable characters for the determination and even the general classification; as for example that of Brongniart, the oldest, simplest, and most comprehensible of those which have been attempted. It admits four general divisions: 1. *Neuropterideæ*. Frond simple or with compound leaflets free or adhering, without middle nerve or merely with a middle nerve at the base, disappearing upward; veins dichotomous or flagellate. 2. *Adiantideæ*. Frond pinnate, bipinnate, or tripinnate; leaflets narrowed to the base, flabel-

FIG. 4.—*Pecopteris louchitica*.

liform, entire or scarcely lobed; veins diverging from the base, without a distinct middle nerve. 3. *Sphenopterideæ*. Fronds of the same kind; veins pinnate or bipinnate near the base; secondary divisions very oblique. 4. *Pecopterideæ*. Fronds simple, pinnate or bipinnate, the leaflets generally adhering by the whole base, or often joined (confluent) at or near the base, then forming lobes, entire or denticulate; secondary veins pinnate, dichotomous or reticulate.—This general classification is still used as a commodious frame for establishing a large number of subdivisions, though many other systems have been proposed since. Among others, the two more important are that of

Göppert, established in his *Genera*, where he especially considers fructifications, and that of Ettinghausen, which fixes with great detail the character of the groups and their subdivisions from similarity of nervation. These different systems are interesting to palæontologists, but present all the same insufficiency resulting from the difficulty of observing the fructification, or from the similarity of the nervation in different species or even genera. Five or six genera of living ferns, for example, exactly limited by the characters of their fructifications, all present in some of their species the same kind of nervation. It is worth remarking, however, that the fossil ferns of the carboniferous measures are in this country more generally found in fruiting specimens than in Europe. The same remark may be applied to the trunks of fern trees, whose scarcity has been generally remarked in Europe as a fact seemingly in contradiction with

in. in diameter, and almost exactly cylindrical. Generally, however, in connection with the roof shale of coal beds, the ferns are mostly bushy or herbaceous species, the shale being composed of soft muddy materials, forming a ground too unstable for the vegetation of large trees.—The

FIG. 5.—*Caulopteris Worthenii*.

what should be expected in considering the great size of the other kinds of vegetables of the carboniferous period. In the coal measures of the United States, these trunks of ferns, named *caulopteris*, *stematopteris*, *psaronius*, &c., and generally classed by the characters of their internal structure or by the scars of leaves upon the bark, are not rare, indeed are extremely abundant in some localities. In southern Ohio and northern Virginia, trunks of ferns are imbedded in a thick bed of sandstone occupying a wide area. These trunks, mostly silicified, are either standing or prostrated, and their fragments are now strewn along the creeks, which by their course through this region have taken off and displaced these remains. They are not only in great number, but some of them are large. The average diameter is 8 in., but some measure more than a foot. A splendid specimen in the museum of comparative zoölogy at Cambridge is 2 ft. high and 14

FIG. 6.—1. *Lepidodendron*. 2. Scars of a larger branch.

club moss or lycopod family is represented in the carboniferous formation mostly by large trees and floating stems, also proportionately large. They belong to several genera, of which the more remarkable are the *lepidodendron*, *sigillaria*, and *stigmaria*. These genera are mostly characterized by the impressions of the leaves forming at the point of attachment rhomboidal, oval, or round scars, which, small in young branches and young stems, enlarge after the fall of the leaves in proportion to the growth of the trees. In species of *lepidodendron* these scars are placed spirally along the trunk and contiguous to each other. In the small branches or immediately after the parting of the leaves these scars are scarcely half a line in diameter on each side; in old trees of the same species the scars are an inch and a half long

FIG. 7.—*Sigillaria*.

and an inch broad. They form either surface or flat impressions, or are more or less deeply cut into the bark. The *sigillaria* species differ essentially from the *lepidodendron* by the position of the scars, which are placed in vertical rows separated by convex or flat

ribs, and generally at a distance from each other. The form of these scars is extremely variable, and, as in *lepidodendron*, their size enlarges in proportion to the growth of the trees. The identification of the species is therefore very difficult, especially when it has to be made, as is generally the case, from fragmen-

FIG. 8.—1. *Stigmaria* with leaves. 2. Stem of *Stigmaria* with scars. 3. Leaf of *Stigmaria*.

tary specimens. It is rendered still more embarrassing by the fact that the bark of some species of *sigillaria* is composed of different thin layers, easily separated, on which the leaf scars, though superposed, differ upon each layer. The club mosses of our time rarely have stems half an inch in diameter; those of the coal, or the *lepidodendron* and *sigillaria*, were represented by trees sometimes 2 ft. in diameter and 40 to 60 ft. high. The *stigmaria* are comparable to the *sigillaria* by their texture; but they were merely floating stems, which, suspended in water by long hollow leaves, had a mode of life independent from that of their flower- or fruit-bearing stems, the *sigillaria*, *lepidodendron*, &c., which came out only when a kind of ground had been formed and consolidated by the growth of the *stigmaria*. The connection of these floating stems with trunks of *sigillaria* and of *lepidodendron* has disposed many palæontologists to consider them as mere roots. But besides many other considerations, the fact that these *stigmaria* did live independently and for long periods without any *sigillaria* stems, even forming by their debris thick strata of clay, is a sufficient reason for recognizing them as true stems. In the peat bogs of our time there is a small club moss, *lycopodium inundatum*, which in a di-

minutive way shows us the mode of life of those *stigmaria*. It expands all around upon the soft muddy surface of the bogs, its creeping stems interlaced in every direction; and when the carpet has become solid enough, the flowering stems come up and ripen their seeds out of reach of the water. The *stigmaria* trunks do not vary much in size from 2 to 4 in. in diameter, but they indefinitely extended their branches by forking, and with their long leaves formed a floating network, soon solid enough to support large trees. The same result is now produced in our peat bogs by the vegetation of the floating mosses. All the scars left at the point of attachment of the leaves of *stigmaria* upon their stems are almost exactly round, like a swollen convex surface one and a half to two lines in diameter, surrounded by a ring and pierced in the centre by a point, the scar of a vessel. The relative position of the scars is more generally in quincuncial order, at a distance of an inch or less; they are sometimes connected by star-like wrinkles, or separated in undulate rows by narrow ridges. The fruits of the lycopodiaceous species of the carboniferous, *lepidostrobus*, are in the form of seeds enclosed in receptacles or spore cases in right angle to a common axis, and forming cones covered with imbricated scales. Their form and arrangement are like those of the club mosses, but the size of the cones is proportionate to that of the trees.

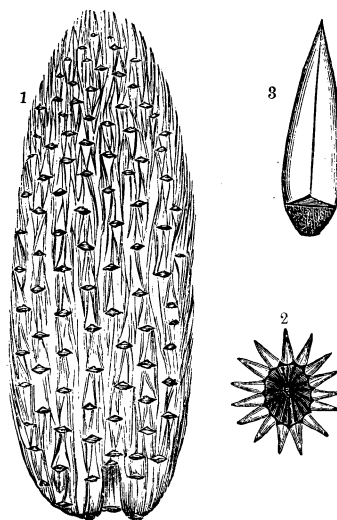

FIG. 9.—1. *Lepidostrobus*. 2. Cross section of a small species. 3. Sporangium and blade of *Lepidostrobus*.

They vary from 1 to 2 in. in diameter, and from 2 to 18 in. or more in length.—The *calamites*, which have left very abundant remains in the coal, are closely related by their hollow articulated stems with bark vertically and equally fluted, by their fructifications, and by their structure, to living species of *equisetum* (horse-

tail). But they have the same enormous proportions in size as remarked for lepidodendron and sigillaria compared with club mosses. Their trunks vary from 1 to 6 in. in diameter, their length from 6 to 40 ft. They appear to have grown close together and in thickets, at least in some localities; for example, near Carbon-

formation of a bed of coal, and of the strata which separate it from the one above it, has demanded a long period of time, sufficient to modify somewhat the characters of the vegetation. It seems therefore that it might be easy to remark and point out the difference between the plants of two subsequent beds of coal. The miners in general appreciate this difference, and indeed it is usually an easy matter for a palæontologist to remark it when his observations are limited to the same locality. But the study is rendered very difficult by the variations in the distribution of the plants as remarked in the same bed at distant localities. The variability acting in two ways, horizontally and vertically, the result of its force in one way or the other can be appreciated only from long researches. In the coal fields of the United States, lepidodendron spe-

FIG. 10.—Calamites.

dale, Pa., such forests of calamites are seen petrified, standing and imbedded in sandstone, their trunks in close proximity to one another. The branches of calamites bear whorls of linear narrow leaves, which have been described as *asterophyllites*. Their fruits, *Wolkmannia*, are cones bearing seeds like those of species of *equisetum*, merely differing by the presence of scales and imbricated in rows. Two other genera, represented by branches bearing leaves also in whorls, appear referable to the same family of calamites, or perhaps to one intermediate between calamites and lepidodendron.

FIG. 11.—*Annularia longifolia*.

FIG. 12.—*Sphenophyllum Schlotheimii*.

One of these, *annularia*, bears linear, lanceolate, thickish, pointed leaflets, sometimes inflated and nearly cylindrical; it resembles *asterophyllites* in its facies; the other, *sphenophyllum*, has cuneate or flabellate leaflets, enlarging upward from the point of attachment.—It is now generally admitted that the

FIG. 13.—1. *Carpolithes*. 2. *Trigonocarpus*. 3. *Cardiocarpus*.

cies predominate in the lower part of the true coal measures, and their remains have especially contributed to the formation of the big vein, B. They gradually disappear in passing up. The sigillaria species are more equally distributed from the base to the middle, while the ferns become more predominant in ascending, especially in small species. The calamites and ribbon-like flabellaria are about in the same proportion through the whole thickness of the carboniferous.—The peculiar distribution of trunks of fern trees in sandstone, which has been remarked upon already, may be taken for evidence in a question often discussed among palæontologists: Do the plant remains found in connection with the coal strata represent the whole flora of the carboniferous period? or was this flora, like that of our present peat bogs,

composed of a limited number of species appropriate by their nature to the growth and composition of the coal, while a different kind of vegetation inhabited dry or high ground? All the specimens of fossil plants found in beds of sandstone, even where no trace of coal is found, represent the same species, or at least the same genera, as those found in connection with coal beds. Hard fruits, resembling nuts and named *trigonocarpum*, *carpolithes*, &c., are locally abundant in sandstone, but sometimes the shale of the coal has them in plenty. Nothing is known as to the relation of these fruits, which have never been found attached to any kind of vegetable remains. They may have been floated by water from a distance, and may therefore, as has been supposed, represent species of plants not found in the true coal basins; but this is very doubtful. The composition of the coal flora, like the formation of the coal over immense surfaces, indicates a great degree of humidity in the atmosphere. The vapors covering the land, extending over the whole emerged surface, developed everywhere the same kind of vegetation, diversified only in its exuberance according to the composition, especially the solidity of the ground. Even the vegetation of the hills, if there were any in proximity to the coal basins, should have been exposed to the same influence. In the southern islands, where fern trees are most common, these plants everywhere follow or ascend the slopes of the mountains in exact concordance with the line of the fogs; therefore a general and permanent degree of humidity should have influenced the same uniform character for the vegetation of the whole land. This seems still better evidenced by the identity of the essential vege-

table types in the carboniferous formation of the whole world. On this subject, however, as on other questions concerning the distribution of the old floras, there is still a great deal of uncertainty, especially caused by insufficiency of materials for observation.

COAL PRODUCTS. The readiness shown by the elements of coal to enter into new combinations where it is exposed to an increase of temperature, and the great variety of the combinations obtained under different degrees of heat, or by the admission or exclusion of air, indicate the close relation of coal to the elements of the vegetable kingdom. It consists of carbon, hydrogen, oxygen, and nitrogen, which make up the great bulk of vegetable matters, and these show the same disposition as in the plants themselves to separate from existing combinations and enter into new. The number of the new products thus formed is almost unlimited. They differ from one another, and from the original substance from which they are generated, as do those obtained in the processes of vegetable fermentation. When heat is applied without access of air, the vapor of water set free acts upon the existing combinations of the elements. These are broken up, and hydrogen and oxygen are evolved under the most favorable circumstances, in their nascent state, to form new compounds with the carbon present, the characters of which vary greatly with the temperature. The process is called dry distillation. By keeping the retorts in which it is conducted at a cherry-red heat, the gases used for illumination are most copiously evolved, the tar itself being decomposed and converted into gaseous matters. (See Gas.) But if the object is to obtain the coal oils, paraffine, benzole, and other hydrocarbons of this

TABLE REPRESENTING THE PRODUCTS DERIVED FROM THE VOLATILE MATTERS OBTAINED IN THE DISTILLATION OF COAL.

Liquids condensed and collected in tar cistern.	Coal tar gives, on redistillation with water or steam	Distilled tar; which affords, on further distillation	Pitch; distilled in ovens, affords...	Pitch coke, Coke oil.	Dead, or pitch oil, consisting of....	Naphthaline, paranaphthaline, and oily hydrocarbons boiling at a high temperature, creosote, aniline, leucoline, paraffine.		
							Crude coal tar naphtha, which consists of	Acids—Rosolic, carbolic, brunolic, creosote. Basis of the pyrole, picoline, aniline, leucoline, methylamine, ethylamine, and other series. Neutral: Allioli, benzole, toluole, cumole, cymole, and other carbhydrogens; naphthaline, hydrate of phenyle (Laurent).
Gases and vapors.....	Ammonical liquor, containing	Water, hydrosulphate, carbonate, muriate, acetate, hydrocyanate, sulphite, and gal- late of ammonia.	Gases and vapors separated in lime purifier	Carbonic acid, Sulphuretted hydrogen, Hydrocyanic acid, Ammonia.	Gases and vapors separated sometimes by additional chemical agents.....	Ammonia, Hydrocyanic acid.		
							Gases and vapors conducted to gas-holder.....	Olefant gas, Vapors of hydrocarbons, Light carburetted hydrogen, Hydrogen, Carbonic oxide.

nature, care is taken that the retorts are heated very gradually, and do not acquire more than a low red heat. The tarry matters thus escape decomposition, and by repeated distillations afford crude naphtha and its secondary products. The foregoing table represents in the clearest manner the great variety of substances besides coke which are obtained by means of this process, and their immediate sources.—Coal tar was for a long time a troublesome product of the gas works, no useful application of it to any great extent being known. It was employed as a covering to protect iron work exposed to the weather; and the pitch obtained by distilling it was found when mixed with earthy matters to be a good substitute for the natural product asphaltum, used for artificial pavement, water-tight covering for roofs, &c. Finally the tar came to be an object of purchase by tar distillers, who learned to extract from it the crude naphtha and also the light oily fluids. The pitch, too, by repeated distillations was made to yield more oily matters, which are useful for lubricating machinery and other purposes. The crude naphtha is now purified by mixing it with $\frac{1}{10}$ its bulk of concentrated sulphuric acid, adding when cold 5 per cent. of peroxide of manganese and distilling off the upper portion. A rectified naphtha is thus obtained, which readily dissolves caoutchouc, and mixed with wood naphtha produces a powerful solvent of various resinous substances, useful in making varnishes. Still further purified, the liquid benzole is obtained, which has been applied to many useful purposes, especially that of an illuminating agent. The light essential oils, as also the heavier qualities which come over after these, are found to possess antiseptic properties, which render them of value for preserving wood from decay. From the essential oils the tar creosote or carbolic acid is obtained, which possesses extraordinary antiseptic properties, and is used in the preparation of a valuable dyestuff called carbazotic acid. The heavy oil yields a substance called aniline, which gives with bleaching powder and other agents a magnificent blue color, and is employed in dyeing. Naphthaline also, which is a solid white substance obtained in large quantities in the distillation of the tar, yields two coloring matters, one called naphthalic acid, and the other chloronaphthalic acid; the latter of which is nearly identical with the coloring principle of madder, and gives with alkalis a beautiful red color. Instead of naphthaline, by conducting the distillation at a lower temperature, may be obtained the waxy substance called paraffine, which is now used for the manufacture of candles and the paraffine oils. The most important of these products will be found more particularly noticed under their separate heads, and the general subject will receive further attention in treating of gas light.—By oxidizing aniline with bichromate of potash a bronze-colored substance is produced, dissolving in alcohol with a

beautiful purple color. In concentrated sulphuric acid its solution is green. On adding water and precipitating with an alcoholic solution of potash, the coloring matter is precipitated unchanged. It is of intense hue, and considered as good if not better than archil; it is very stable, not being decomposed at a temperature of 482° F. One pound of the solid substance will dye 200 lbs. of cotton a moderately dark lilac, the color standing well the action of light and heat, acids and alkalis. The distillation of coal for obtaining paraffine and the oil accompanying has been conducted in the following manner: The retorts used are like those employed in making gas. A worm passes from them through a refrigerator kept at a temperature of about 55° F. The oil condenses in the worm, and is collected in a receiver. It deposits some paraffine when cooled to a low degree. Some illuminating gas is generated in the process and escapes. Coke also remains in the retort, as in the gas-making process. The oil is purified by heating a cistern of it to about 150° F. Water and insoluble impurities subside on standing, and the oil may be drawn off. It is redistilled to dryness, and a carbonaceous residuum is left in the iron still. From the cold condenser it is run into leaden vessels, and $\frac{1}{10}$ its bulk of oil of vitriol is added and the mixture is well stirred for an hour. In 12 hours the sulphuric acid has settled, together with the impurities it has taken up. The oil is then drawn off into an iron vessel, and 4 gallons of a solution of caustic soda, of sp. gr. 1.3, are added to every 100 gallons of oil. This is well stirred for an hour, to take up all the remaining acid, and it is then left for 6 or 8 hours for the soda and impurities to subside. The oil is again drawn off and distilled. Paraffine oil thus obtained contains a more volatile oil, that may be mostly separated from it. Half its bulk of water is added to it, and the mixture is distilled as before, the boiling being continued for 12 hours by renewing the loss in the still with more water. The steam carries the more volatile fluid over with it. They condense in the worm, and separate by standing in the receivers. This fluid is suitable for burning in lamps and for other purposes. The oil left in the still is to be drawn away from the water left with it, purified by distilling from $\frac{1}{10}$ its bulk of sulphuric acid, and then from chalk added as the caustic soda was used. The oil is kept for a week in a warm place, and being then drawn off from the sediment is fit for lubricating or illuminating purposes. Cooled to 30° or 40° F., the paraffine crystallizes, and may be collected by pressing out the oil through cloths.—An improvement made upon this process consists in introducing highly heated steam into the retorts with the bituminous matters. It rapidly unites with and carries off the volatile matters arising from the coal, checking their conversion into gas, and greatly increasing the amount of oily or condensable product. The condenser is kept at a temperature of

about 55° F. The products obtained are next distilled, and very hot steam is introduced again, if much paraffine rather than oil is desired. At different stages of the process different products are obtained, which are separately collected. These are, first a thin, impure eupione oil, to the extent of about one eighth of the fluid; then a thicker and heavier oil, containing paraffine, amounting to two fifths or one half of the fluid; and lastly, paraffine mixed with heavy oil. The crude eupione oil is purified by adding 5 to 10 per cent. of sulphuric acid, diluted with an equal bulk of water, and half as much by weight of bichromate of potash as of the acid. Heat is then applied, and the mixture is well stirred while heating. When it has reached the temperature of 212° F. it is allowed to cool and settle. The eupione, being drawn off, is next treated with a warm solution of caustic soda, and left to settle. It is at last taken off from the heavier fluid and distilled. The heavier oil is treated very much in the same way, the black oxide of manganese instead of the potash salt being sometimes used with the sulphuric acid. The first comings over in the distillation are added to the eupione oil; but the greater part is the so-called "lubricating oil," the most important product of the process. The last portions are thick like butter, and yield mostly paraffine when treated with that already obtained with the heavy oil. This, after being allowed to crystallize in a cool place, is put in a bag for the oil to drain away. It is then pressed, melted, and when cold pressed again, the oil being added to that already obtained. It is melted again, and at the temperature of about 400° F. from 5 to 10 per cent. its weight of strong sulphuric acid is stirred in. On boiling, the remaining oil is completely charred, and on cooling settles as a black powder. Another boiling after separating this powder completes the purifying process, though the paraffine is now after several new methods bleached to a beautiful degree of whiteness. Its properties will be described in the article PARAFFINE.—Coal oils have been manufactured at several localities in the United States. Important works at Cloverport, in Breckenridge co., Ky., on the Ohio river, were destroyed by fire in 1858. They produced large quantities of an oil of excellent quality, which was on trial with a view to its being introduced into our lighthouses; but all the coal oil distilleries have been closed by the discovery and wonderful production of petroleum, which amounted to 539,472 barrels in the month of June, 1872, from the Pennsylvania oil regions alone. Not only the cannel coal and other fat coals produce these oils, but the bituminous shales, until of late years regarded as worthless, have been applied at Dartmoor, in the west of England, at Autun, France, and at Bühl in Prussia, to the same purpose.

COAN, Titus, an American missionary, born in Killingworth, Conn., Feb. 1, 1801. He studied theology at Auburn seminary, was ordained

as a Congregational minister in Park street church, Boston, in 1833, and the same year went upon an exploring mission to Patagonia, landing near the strait of Magellan. Finding the country unfavorable for the establishment of a mission, he returned to New London, Conn., and thence sailed for the Hawaiian islands, where he arrived in June, 1835, and was stationed at Hilo, on the island of Hawaii, where he has since resided. Apart from his successful missionary labors, he has made valuable contributions to the knowledge of volcanic eruptions, published in the "American Journal of Science" and in the "Missionary Herald."

COANZA, a river of S. W. Africa, flowing into the Atlantic ocean on the coast of Lower Guinea, south of St. Paul de Loanda, in lat. 9° 20' S. and lon. 13° 12' E. Its source is supposed to lie eastward of Bihe, between lat. 12° and 13° S. and lon. 17° and 18° E. Its general course thence to the sea is in a north-westerly direction. The entire length of the river is estimated at not less than 500 m. The entrance to the Coanza is obstructed by a bar at its mouth, though the river is navigable for light-draught steamers, if they could gain access to its waters. At the confluence of the Lucalla, over 100 m. inland, it is about 150 yards wide. Canoe navigation extends to Cambambe, 150 m. from the sea, where further ascent is prevented by a large waterfall. There is another cascade above this, at the junction of the Lombe with the Coanza, in lat. 9° 41' S. and about lon. 16° E., where Livingstone says hippopotami and elephants are frequently swept over and killed. Here the current is rapid and flows over a bed of sandstone rock, with pebbles. A fresh-water fish called *cacasu* is caught in the river, and is highly relished by the natives, who eagerly purchase it from the fishermen. Shell fish also occur. In the lower part of its course the Coanza forms the boundary between Angola and the other Portuguese dominions on the west coast of Africa. The rich, level, and productive Portuguese settlements of Cambambe, Massangano, Muxima, and Pungo-Andongo border upon its banks. Magnetic iron ore is still worked near Massangano, where are the ruins of a massive foundery erected by the marquis of Pombal in 1758. A canal to connect the Coanza with St. Paul de Loanda was commenced by the colonial government early in the present century, but remains unfinished.

COARI, or **Coary**, a river of Brazil, having its whole course in the province of Alto Amazonas, runs N. E., forms the boundary between the districts of Teffe and Coari, traverses a considerable lake, and divides near Alvellos into two arms, which join the Amazon. Length of the river, 285 m.

COAST RANGE, or **Coast Mountains**, a mountain range of California, nearly parallel with the Pacific coast, and extending from near the boundary of Oregon into the peninsula of Lower California. Its width is from 30 to 40 m.

and it is divided by the bay of San Francisco. S. of lat. $34^{\circ} 20'$ N. a plain from 25 to 40 m. wide lies between the mountains and the sea, the spurs being short and running at right angles with the main ridge; N. of that, the spurs form the greater part of the coast line. The principal of these S. of the bay of San Francisco are the Santa Susanna, Santa Inez, Santa Barbara, and Santa Lucia ridges. E. of the bay is the Contra Costa ridge, which is crossed by the Gabilan ridge. N. of the Gabilan are the Sonoma and Carneros ridges, beyond which the spurs are so numerous and closely connected that they are scarcely distinguished by name. These spurs are separated by fertile valleys, some of which are 60 m. long by 10 m. broad, watered by streams, and possessing a genial and equable climate. The most noted are the Los Angeles, Salinas, Santa Clara, Sonoma, and Napa valleys. The principal peaks of the main ridge are Mt. Ripley, 7,500 ft. high, in lat. $39^{\circ} 8'$; Mt. St. Helena, 3,700 ft., lat. $38^{\circ} 40'$; Monte Diablo, 3,881 ft., lat. $37^{\circ} 50'$; Mt. San Bernardino, 11,600 ft., lat. $34^{\circ} 20'$; and Mt. San Geronio, 7,000 ft., lat. $33^{\circ} 48'$. N. of all these are Mts. Linn and St. John. The principal passes are S. of the outlet of the Sacramento basin. The northernmost, Livermore's pass, lat. $37^{\circ} 42'$, is 686 ft. high; the others are mostly higher, the two southernmost, San Geronio and Warner's, lat. $33^{\circ} 10'$, being respectively 2,808 and 3,780 ft. high. Nearly all the spurs, valleys, and streams of the range run to the west. The Coast mountains are steep and rocky. N. of lat. 38° they are covered with timber and brush; S. of that the ridges nearest the ocean have some timber, and those further inland are nearly bare. The main ridge, near the head of the Sacramento valley, is called Trinity ridge; near Monte Diablo is the Diablo or Bolbones ridge; S. of lat. 34° is the San Bernardino ridge, and in one place the Cuyamaca mountain.—A range of mountains in the N. W. part of Oregon, running parallel with the sea, is also designated the Coast range. The Calapooya mountains connect it on the south with the Cascade range.

COAST SURVEY, United States. The coast survey of the United States is a national undertaking of high character and importance. Having an extended and dangerous seacoast, with a large foreign commerce, in the pursuit of which many thousand vessels annually enter and leave our ports, with an immense coastwise trade which employs many vessels and thousands of seamen, it is plainly our duty as a nation to provide every means which science and practical skill can afford for pointing out the dangers to which this commerce is exposed, and to furnish every facility for its successful prosecution. To accomplish these objects the coast survey was founded. It is designed to furnish accurate maps of the whole coast; to point out the positions for lighthouses, beacons, and other signals; to determine the character

and course of the currents of the ocean along our shores; to develop and determine the laws of the tides; to ascertain the prevailing courses of the winds and the general laws of atmospheric influence, the changes which take place at the entrances of our harbors, the character of the bottom of the sea within the limits of soundings, and all other questions which contribute to a thorough knowledge of our coast and its adjacent waters. It has also the further object of distributing this knowledge throughout the world, so that all nations may partake of its advantages. For the accomplishment of these objects a wide range of application of the practical sciences is required. Astronomy and geodesy furnish the means of projecting maps. The highest forms of mathematical science are required in the investigation of the laws of the tides and the figure of the earth. Geology explains the changes which are constantly taking place in all our harbors and rivers, and in the general form of the coast. Natural history accounts for the formation of those coral reefs in the southern waters, so long the terror of navigators, predicts their growth and extension, and investigates the forms of animal life at the bottom of the sea, thus affording new and unexpected aids to navigation. Physical science furnishes the electric telegraph, by which longitudes are determined, and the electrotype and photograph, by means of which engraved plates and charts are indefinitely multiplied. The mechanic arts supply the most delicate instruments; and the industrial arts of drawing, engraving, and printing are all required in their greatest perfection. For the expanded conception of this great institution as it now exists; for the administrative skill which has perfected its organization; for the solution of many interesting questions of science which it has involved, especially those of the tides, the Gulf stream, and the magnetic force; for the genius which has brought to the highest perfection the scientific methods employed; for the untiring labor which, within a comparatively short period, has produced greater results than any other institution of the kind, the world is greatly indebted to Prof. A. D. Bache, the late superintendent. Since his death the work of the survey has been greatly extended, and its usefulness increased, by the present superintendent, Prof. Benjamin Peirce. The most important work set in operation since his accession to the position of superintendent is the great national triangulation—a geodetic survey which is intended to embrace the shores of the Atlantic and Pacific within its limits, and to form by means of triangulation a grand chain across the continent, which will serve in a most satisfactory manner to verify the independently determined longitudes of the Pacific coast. This great work, together with the other improvements which have been made under the rule of the present superintendent, will be referred to in another place.—The first

attempt to organize a national coast survey was made in 1807. In that year President Jefferson in his message to congress recommended the establishment of a national coast survey, "for the purpose of making complete charts of our coast, with the adjacent shoals and soundings." It is believed that to Prof. Patterson of Philadelphia is due the honor of having first suggested to the president the idea of a geodetic survey of the coast. At that time the only charts of our extended and dangerous seacoast were those of the "Atlantic Neptune" of Col. Des Barres, Romaine, and Gaudel, and compilations from those works by English and American publishers. Congress passed an act authorizing such a survey, and appropriated \$50,000. Mr. Gallatin addressed circulars to the principal scientific men of our country, requesting their opinions with regard to the best methods of conducting the proposed work. The plan proposed by Mr. F. R. Hassler was adopted. The plan was, essentially, to establish the positions of certain prominent points of the coast by astronomical observations, and to connect these points by trigonometrical lines, so as to form a basis upon which the nautical survey could be made. Mr. Hassler, a native of Switzerland, had been engaged in the trigonometrical survey of that country, and was eminently fitted by his scientific attainments for the execution of the task to which he was now called. On account of the threatening nature of our relations with Great Britain, nothing was done toward the actual prosecution of the survey till 1811, when Mr. Hassler was sent to Europe for the purpose of procuring the necessary instruments and standards of measure for commencing the work; and the war which followed caused him to be detained abroad as an alien enemy till 1815. On his return he was formally appointed superintendent of the coast survey, and commenced his labors in the field in 1817, in the vicinity of New York. His first work was the measurement of a base line in the rear of the Palisades, on the Hudson, as a foundation for the triangulation of New York harbor and the adjacent coast. Before he could publish the results of his first year's labor, however, the coast survey was effectively discontinued; and another interval of ten years elapsed, during which some additions were made to a knowledge of our Atlantic coast through detached surveys of a few of the more important harbors, made by the navy and the topographical engineers of the army, and those of the Messrs. Blunt. In 1828 Samuel L. Southard, secretary of the navy, urged upon congress the importance of reestablishing the coast survey upon its original plan; and in 1832 Mr. Hassler was restored to his position, and enabled to resume the work. A quarter of a century had now elapsed since Mr. Hassler first urged his scheme of a thorough trigonometrical survey. He continued to superintend its operations until his death in 1843,

when the survey had been extended from New York eastward to Point Judith, and southward to Cape Henlopen. He was succeeded by Prof. A. D. Bache.—On assuming charge of the coast survey, Prof. Bache saw the necessity of extending the plan so as to embrace all the objects of which we have spoken. He urged upon congress the importance of carrying on all the principal operations at different points of the coast at the same time; the different sections to be conducted on the same general principles, and to be ultimately connected, so as to form a complete and continuous work. He saw that the great characteristic feature of the Atlantic, the Gulf stream, must be investigated; the laws of the tides developed, so that navigators might be furnished with correct information regarding their ebb and flow in the harbors and rivers; the infinite maze of currents produced by the tides, the Gulf stream, and the winds, combined, threaded out, and mapped; the magnetic force of the earth studied, and its laws along our coast determined; the changes of the weather at different seasons of the year, and the laws of storms, investigated. All these conceptions were far beyond any that had been entertained; and Prof. Bache at once organized those systematic observations which extended through the whole period of his administration, and are continued at the present day. The most important results to navigation and to science have been and are being developed by these observations. Under this plan of reorganization, as it may be called, the survey continued to advance with great success until the breaking out of the late civil war. By the secession of the southern states their immense seaboard became hostile coast, and the peaceful operations of the coast survey of necessity ceased. Several vessels employed in the work were captured, and some of the officers narrowly escaped. Debarred from the direct prosecution of the survey of the southern coast, Prof. Bache sought to turn at once to practical account the knowledge of the harbors and their adjacent coasts along the southern seaboard which his officers had acquired during the progress of their labors. Topographical engineers being much needed in the army, he supplied skilled topographers from his own corps. Pilots being necessary for the squadrons which operated on the enemy's coast, he furnished officers of the survey whose local knowledge enabled them safely to pilot the largest vessels of war into harbors from which buoys, lights, and all other aids to navigation had been purposely removed, and whose hydrographic knowledge enabled them in a short time to replace the old marks by others better adapted to the purposes of navigation. During the war there was not an army in the field without one or more coast survey officers attached to the staff of the general commanding, as topographers, and rendering most efficient service; and no

important naval demonstration was made upon the coast without the presence of some officer from the same service on the staff of the admiral commanding the fleet. The services thus rendered to the country during the war by the officers of the coast survey were of the utmost importance, and were thoroughly appreciated by the government. Added to this, the accurate charts of the coast and harbors which had been already made and published were of the greatest assistance to our vessels in their cruises up and down the coast. Worn down at length with the labors of a busy life, Prof. Bache died in 1867, and Prof. Benjamin Peirce was installed as superintendent Feb. 26, 1867. Since his accession Prof. Peirce has continued with vigor the system inaugurated by his predecessor, and has greatly extended and enlarged the sphere of usefulness of the coast survey. The great system of a national triangulation, which extends the geodetic work, heretofore confined to the sea-coast, across the whole continent, owes its existence, and in a great measure its conception, to the present superintendent. This work, which is now (1873) in successful operation, contemplates the establishment of a system of triangles connecting those already determined on the Atlantic with those on the Pacific coast. Thus in every state and territory geodetic points will be established and accurately determined; and thus will be formed a base for a thorough topographical survey of the several states, which will equal if not surpass in beauty and accuracy the famous ordnance survey of Great Britain, while in point of magnitude and extent it will surpass anything in the world. Prof. Peirce, on assuming charge of the survey, encountered some difficulties in the way of a vigorous prosecution of the work. As before mentioned, several of the vessels belonging to the survey had been captured during the war; others were very old, and many were completely worn out and unfit for service; and the small number remaining were totally inadequate for such activity in the field as had always heretofore existed. But these difficulties are rapidly being overcome. Prof. Peirce has urged upon congress the passage of special appropriations for the building of new vessels, and several fine ones have already been built and are at work upon their stations. The survey of the Pacific coast, which had been somewhat disorganized owing to the war, he established upon a new and firm basis, with an experienced officer at its head; and the work upon that coast has proceeded with unexampled rapidity. Much valuable scientific information has been obtained by the observations of the solar eclipses made by the superintendent and his assistants, under special acts of congress, in 1869 and 1870. Much has been done, and very valuable information collected, through the observations for deep-sea temperatures; and the many thousand specimens collected from the bottom of the sea at great

depths have added much to our knowledge of the character of the great sea floor. The investigations which have been made of the tides are of great importance; they will be referred to in their proper place. A directory or coast pilot of the Pacific coast has been published for the use of mariners, and one is in preparation for the Atlantic and gulf coasts. Every year increases the general usefulness of the survey and the vigor and success of its prosecution.—These general facts with regard to the history and progress of the United States coast survey being stated, we come to the scientific and practical operations involved in its execution. An explanation of these operations will embrace a variety of topics, and only a brief notice of each can be given. The first object of a work of this kind is an accurate determination of the shore line. This is done entirely by operations upon land. The object of a map or chart is, of course, to give a miniature representation of a portion of the earth's surface upon paper, in such a manner that the different parts of the drawing shall have the same relative positions and dimensions as are found in nature. To determine these dimensions by linear measurement, for the purpose of reducing them to the scale of the drawing, would be practically impossible; and hence the use of geodetic or trigonometrical surveying.—*Geodesy—General Remarks.* To illustrate this mode of measuring distances and establishing the relative positions of points on the earth's surface, let us suppose ourselves to be situated on a level plain, surrounded in the distance by high mountains, and that we wish to determine the distances from our position to the tops of those mountains, and the distances of the different mountain peaks from each other. A line is measured on the plain, of such a length that if two lines be drawn from its extremities they will intersect at a considerable angle, and form with the measured line a triangle of proper dimensions. Then, knowing the length of one side of this triangle, we may compute the length of the other two sides by a simple theorem of trigonometry, without any further labor than measuring the angles of the triangle. Taking now either of the computed sides as a new base, we may establish a second triangle upon this, and thus fix the position of another point. A third point may be established in the same manner, gradually expanding the system until the whole region we wish to embrace in the map is covered with a network of triangles; the length of the lines having been computed by measuring the first only, and then measuring the angles of the triangles. For the purpose of a map or chart, there are still two important elements wanting. We have yet no means of knowing the direction of any one of these lines with reference to the meridian, nor the place which the points occupy on the surface of the earth. The survey thus far will give no means of knowing whether

any two points are situated in a north and south or an east and west line; nor whether its site is near the equator or near the poles, or to the east or west of the first meridian. These wants are supplied by astronomical observations, by which the latitude and longitude of some point, and the directions of the lines with reference to the meridian, are determined. The system of triangles which we have described may be extended over large areas, or along a coast for several hundred miles, depending upon one measured base line. By determining the positions of the extremities of the base line and its direction by astronomical observations, the positions of all the other points of the system and the direction of the lines may be computed after the angles have been accurately measured. Accuracy requires that the computed positions should be frequently verified by actual observation, and the computed lengths of the lines occasionally verified also by the introduction of a measured base of verification. The geodetic work thus involves the measurement of the base line, the measurement of the angles of the triangles, and astronomical determination of the latitude and longitude of the different points, and of the directions of the lines with reference to the meridian. This last is called the measurement of an azimuth.—Reconnaissance is the first operation in order. An experienced officer first travels over the country to be surveyed, and makes a preliminary examination for the purpose of selecting the trigonometrical points which will best fulfil the required conditions. Elevated positions are generally chosen, from which extended views can be taken. A site for a base line is selected on some level plain for convenience of measurement, and from which the triangulation can easily be expanded. In the selection of geodetic points great judgment is required; as upon this depends in a great measure the economy, accuracy, and success of the work.—*Base Line.* For the measurement of the base line a standard must be adopted. The English use the yard, which is also the legal standard of length in the United States. But in the coast survey measurements the French *mètre* is used, which is more convenient on account of bearing a certain relation to the magnitude of the earth, being equal to the ten millionth part of the earth's quadrant. The metre bar used as standard in the coast survey is one of those originally made by the French committee of weights and measures. For the actual measurement of base lines rods of wood, metal, or glass have been used; but the changes of length caused by changes of temperature in a simple bar of any material have rendered it desirable to construct a special apparatus for the purpose, upon a compensating principle, which will retain the same length under all temperatures. The base apparatus of the coast survey, devised by the late Prof. Bache, is considered the best known. It has not only the same length at all stationary tem-

peratures, but preserves it also while the temperature is changing. Bars of different metal, having the same dimensions and exposed to the same source of heat, will not heat equally in equal times. The thickness and surface of the bars are therefore so proportioned to their relative power of conducting and absorbing heat, that they will equally follow changes of temperature. The principle of the level of contact has been applied to the apparatus; and the exactness of its operations is so great that lines of seven or eight miles in length may be measured with a probable error of only a fraction of an inch. Two sets of compensating bars are used, each 6 metres (nearly 20 feet) in length. Mounted on trestles, provided with every mechanical movement for adjusting the bars in height and direction, this apparatus is handled with such facility that on favorable ground a mile may be measured in an ordinary working day.—*Triangulation.* For the measurement of the angles theodolites of the most accurate construction are used. In the primary work on the Atlantic coast a large theodolite with a circle 30 inches in diameter is employed. This is carried to the summit of the hill or mountain where the angles are to be measured, and established carefully over the station point, where it is left standing until the measurements at that point are completed. The party having this work in charge live in tents, or in some convenient dwelling near at hand, so as to take advantage of the occurrence of favorable weather for the observation of distant signals. The instrument is furnished with a powerful telescope, which will give a distinct view of such signals. The signals are usually straight poles supported by a tripod, erected at the various points; but on the long lines an instrument for giving signals is used, called a heliotrope. This is simply a round mirror about the size of a silver dollar, so mounted on a telescope that an assistant at any distant station is able to reflect the rays of the sun in the direction of the observer. The telescope is used to direct the instrument correctly toward the central position at which the observer is stationed. It is not unusual to see the heliotrope on the summits of mountains 80 or 90 miles distant, when the outlines of the mountains are not visible. The measurement of the angles at a primary station occupies three or four weeks. It is found to be impossible to work during the middle of the day, on account of the agitation of the atmosphere caused by the heat of the sun; and hence only about two hours in the morning and evening can generally be devoted to this work. Each angle is determined by about 30 measurements; and as at each station there are from 10 to 20 angles to be measured, only two or three primary stations can be occupied in one season. Depending upon the primary triangulation, and controlled by it, a network of secondary and tertiary triangles is formed along the seacoast, extending up the bays and rivers. The angles are mea-

sured with theodolites more portable than the one above mentioned, the circles varying from 6 to 12 inches in diameter according to the distances to be observed. These triangulations determine the relative positions of prominent points, at distances averaging from two to five miles, and thus form a skeleton map, in which the details of configuration of shore line and surface remain to be supplied by the topographer. If the figure of the earth were precisely known, it would suffice, in order to fix the situation of the whole network of triangles on the surface of the earth, to determine the latitude and longitude of some one point, and the direction with reference to the true meridian of one of its lines, *i. e.*, its azimuth. But, owing to the irregularities of the earth's figure, it is found necessary to repeat the determinations very frequently, by which means the work is checked and any accumulation of error avoided.—*Latitude.* All the known methods of determining latitude have been used in the coast survey, for the purpose of ascertaining their relative merits. Large vertical circles or repeating theodolites were first used for observing double altitudes; but these made way for more perfect and larger instruments, the zenith sector, the prime vertical transit, and the zenith telescope or equal altitude instrument. The first mentioned of these instruments, constructed according to the plan of Prof. Airy, gives very satisfactory results; but it is rather heavy for transportation, and the observations are laborious. The method of determining latitudes by observations of transits of stars over the prime vertical, first used by Bessel, is admirable in theory, but in practice a great loss of time and labor is often caused by clouds. The zenith telescope, or equal altitude instrument, was first applied to the determination of latitudes by Capt. A. Talcott, a former officer of the United States army; it has been remodelled and specially adapted to the purpose in the coast survey, where it has become a favorite instrument on account of the great number and accuracy of the results that can be obtained in a given time, and the facility with which it is used. A large number of observations (from 150 to 200) are made at each station, and the mean is taken as the result, the uncertainty of which is thus reduced to a small fraction of a second. Mr. George Davidson has devised an instrument, now in successful use both on the Atlantic and Pacific coasts, which combines in a simple and beautiful manner the principles of both the zenith telescope and the transit instrument, so that observations for longitude and latitude may be made by the one instrument at the same station. This instrument gives general satisfaction for its compactness, delicacy, and accuracy, and will doubtless soon be in general use.—*Longitude.* For the purpose of determining the longitude of all points in the coast survey, with reference to Greenwich and other European observatories, it is only necessary to ascertain that of one point,

the difference of which from all others is known by the triangulation, and by differences of longitude obtained by means of the electric telegraph. The observatory of Cambridge, Mass., has been used as such a point of reference. Its longitude from Greenwich has been determined by astronomical observations of eclipses and occultations of stars by the moon, and of moon culminations, made not only there, but at other observatories in the United States, the longitude of which from Cambridge has been determined by electric telegraph. Besides the astronomical methods, a chronometric method has also been used. A large number of chronometers have been transported repeatedly and in different years between Cambridge and Liverpool, for the purpose of comparing the time of the observatories at those places. The results of these expeditions, in which special regard was had to the effect of temperature on the rates of the chronometers, show a pretty close agreement in different years, but differ from those by astronomical observations by about two seconds of time. The telegraphic determinations of longitude have been extended from Washington northward to Philadelphia, New York, Albany, Cambridge, Bangor, Calais, and Halifax; southward to Petersburg, Wilmington, Charleston, Savannah, Pensacola, Mobile, and New Orleans; and westward to Cincinnati, St. Louis, Salt Lake City, and San Francisco. Most successful results have also been obtained from the telegraphic campaigns between Heart's Content and Valentia over the British Atlantic cable; and equally good determinations have been secured between Havre, France, and Duxbury, Mass., over the French submarine cable. The results have been entirely satisfactory, and have given the difference of longitude between Greenwich and Cambridge within the smallest limits of error. Through these methods the longitude of San Francisco on the Pacific coast is as accurately known as that of Cambridge or Greenwich. In the telegraphic method, which is by far the most accurate for determining difference of longitude, the coast survey has taken the lead, and has brought it to a state of perfection which subsequent operations of a similar nature executed in Europe have not yet reached. The idea of comparing the local time of different places by means of the electric telegraph is sufficiently obvious, and dates from the conception of the telegraph itself. But the refined methods by which the intervention of human senses and operations, and the consequent liabilities to error, are in the greatest possible degree avoided, and by which the time of transmission is measured and eliminated from the longitude, have been the result of careful study and long experience. The first experiments on the velocity of galvanic signals were made in 1848. They have since been frequently repeated; and the velocity is found to vary from 10,000 to 20,000 miles per second, according to the size and kind of wire em-

ployed. The manner in which this experiment is made is essentially as follows: An astronomical clock is so connected with the telegraph wires as to graduate by its beat slips of paper delivered with uniform velocity into spaces representing seconds of time, each about an inch in length, both at the place where the clock is and at some distant station. If now, at the latter station, arbitrary signals are made between those given by the clock, and transmitted to the clock station, the corresponding marks on the register of that place will appear later, or more distant from the preceding clock marks than on the register where they are made. The difference measures the whole time of transmission from the former to the latter station and back again. On the Pacific coast, besides the telegraphic determinations already spoken of, longitudes have been determined by the astronomical methods and also by chronometric expeditions. In 1860 an expedition was undertaken from Point Hudson, Admiralty inlet, to Gray's harbor, Washington territory. In 1861 another was made between San Francisco and Coos bay in Oregon. In 1867 the first Alaska expedition was undertaken from San Francisco, during which the ports of Victoria, Port Simpson, Sitka, St. Paul's harbor, Captain's harbor, Port Lincoln, and Stony island were visited. In 1869 the second Alaska expedition took place, and Astor point in Columbia river, Esquimalt on Vancouver's island, Victoria, Fort Wrangel, Kok-klux, and Sitka were visited. In 1869 an expedition was made from San Francisco to Eureka in Humboldt bay, California; and in 1870 another between San Francisco and Punta Arena.

—*Azimuth.* The direction of the meridian is determined by observations on the pole star, or other close circumpolar stars, at the time of their passing the meridian, or of their greatest eastern or western elongation. The angle between the vertical plane passing through the star and that passing through one of the triangle sides is measured with a theodolite. The angle which the former plane makes with the meridian can be computed from the time of observation and the star's place; and thus the azimuth, or true bearing of the triangle side, becomes known, as well as the bearing of all other sides connected with it by triangulation.

—*Topography.* This is a representation on paper of the natural features of the country. The outlines of the shore, the irregularities of the surface, the forms and dimensions of hills, forests, streams, rocks, meadows, towns, and villages, are all represented by certain conventional modes of drawing, well understood by those who make use of the maps. The drawing presents to us the surface of the earth as it would appear to an observer from above it. The surveyor uses a table or board on which is fitted a sheet of drawing paper. On the latter several points of the triangulation are already plotted. For the mapping and delineation of intermediate points use is made of the alidade

in connection with the plane table, as the table mentioned above is called. The plane table is a well seasoned drawing board, about 30 inches in length and 24 in width; it is usually composed of several pieces of wood grooved together in such a manner as to prevent warping, and is supported upon three brass arms which are connected with and supported by a tripod arranged with levelling screws. The sheet upon which the country is to be mapped is fastened to the table by means of brass clamps. The alidade consists of a brass rule about 22 inches long, having a circular level on its upper face. Near the middle of the rule is a perpendicular cylindrical column of brass called the standard; on the top of this standard is a square brass plate, which supports four columns; these in their turn uphold two cross pieces, upon which rests the axis of a telescope. To one end of the axis is attached a vertical arc, which is used in the measurement of vertical angles for heights. The telescope itself has the usual cross bars and means of focal adjustment. In practice the operation of the plane table is as follows: The surveyor places his table upon the ground, properly adjusts it by the levelling screws, and determines its position on the sheet by drawing lines on the paper, in the directions of at least three of the trigonometrical points. The intersection of these lines on the paper will give the position which his table ought to occupy on the map. Having fixed this point, he directs the telescope of his alidade to any prominent points in sight, and draws lines in their direction by means of the ruler. Then going to a second point, and fixing his position in the same way, he sights to the same objects as before from his new position. The lines thus drawn on the sheet will fix by their intersection the places of all these points on the map. It is in fact a practical continuation of the triangulation on a minute scale. Accidental details of ground and slight irregularities of shore line may be drawn by the eye. The topographical maps are generally surveyed on a scale of $\frac{1}{10,000}$ of the natural dimensions. In localities where a great amount of detail is to be represented, such as large cities and their vicinity, a scale of $\frac{1}{5,000}$ is employed; and in some special surveys so large a scale as $\frac{1}{1,000}$ has been used. On the other hand, on flat and thinly settled ranges of the coast, a scale of $\frac{1}{20,000}$ is employed. The extent of ground represented upon a single topographical sheet depends upon the scale. On a scale of $\frac{1}{10,000}$, or about six inches to the mile, a square foot of the drawing represents about four square miles of the surface of the earth. The metre chain, which was frequently used in topographical work to determine distances where the usual means of intersection could not be applied (as in roads, on beaches, &c.), is now to a great extent superseded by a simple but very useful instrument called a telemeter. This, as used in the coast survey, is simply a scale of equal parts, painted upon a wooden rod

10 feet long, 5 inches wide, and $1\frac{1}{4}$ inch thick, so graduated that the number of divisions upon it, as seen between the upper and lower horizontal wires of the telescope of the alidade, is equal to the number of units in the distance between the observer's eye and the rod held at right angles to the line of sight. In all cases it should be graduated experimentally for the particular instrument and eye of the observer who has it in use. Thus the topographer, without moving from his position, can determine with accuracy the distances from him of any number of points within 300 metres. The telemeter has given very satisfactory results.—*Hydrography.* The survey of the land having been completed by the method detailed, the hydrographer is ready to plot his soundings and observations in their proper places on the map. Under the head of hydrography are placed all those operations which are performed at sea for the determinations of the positions of the rocks and shoals, the depths of the water, and the investigations of tides, currents, &c. The principal labor is that of sounding. With the outlines of the shores furnished by the topographer, the hydrographer has only to measure certain angles upon the shore signals at regular intervals in the progress of a line of soundings, and the position of his boat or vessel on the line is thus determined, and of necessity the soundings taken on the line. These determinations are so accurate that the navigator may run his course by the soundings given on his charts. The angles are measured by a sextant, and the positions plotted upon the chart. In practice, the position of the boat is determined at intervals which vary according to the depth of water, the speed of the boat, the force of the tidal current, the frequency with which the soundings are taken, and the character of the bottom. Thus in strong tideway, or in a rocky and uneven bottom, angles would be taken at very short intervals; while in smooth even bottom as much as five minutes is often allowed to elapse between any two angles. The intermediate soundings, being taken at equal intervals of time, are laid down at equal intervals between the positions determined by angles. The number of soundings is generally so great that the features of the bottom of the sea, within a wide belt adjacent to the coast, are almost as well determined as those of the land; and with the further assistance of the specimens of the bottom which are brought up by the sounding-lead, the mariner may during foggy weather determine his position with considerable accuracy by soundings alone.—*Physical Hydrography.* The hydrographer determines the soundings along the coast and in the various harbors, the position and extent of the various shoals and rocks and the depth of water upon them, the rise and fall of the tides, the direction and velocity of the currents, and the various changes that take place in the channels and bars of our coast. Physical hydrography has for its prov-

ince the investigation of the causes of these changes, with a view to determining the laws upon which they depend, and if possible to provide remedies. It studies in particular the whole subject of tidal currents, and their effect upon the harbor channels; the effect upon these channels of the increase of wharf lines in cities; the improvement of harbors by breakwaters and sea walls; the action of the sea upon beaches; and all of the many questions which arise in the discussion of the laws of change in harbors and on the coast. The coast survey has done much in the way of investigations in this science, especially in the harbors of Boston and Portland. In the latter city extensive operations are in progress for improving the Back bay, the result of the recommendations of the present superintendent, based upon surveys and reports made by his officers. In Boston a most extensive system of improvements has been going on for years, which will in a short time greatly increase the value of that already excellent harbor. At Edgartown and Vineyard Haven in Massachusetts, at the harbor of Nantucket, and at Chatham, examinations have been made and improvements projected, which will ultimately redound greatly to the advantage of those harbors. Constant observations are made in New York harbor and its vicinity, and such improvements suggested as will arrest any unfavorable changes in the channel. This is a work of great labor and importance, and is increasing in success and usefulness year by year.—*Tides.* One of the most difficult questions presented to men of science is the solution of the problem of the tides. The importance to the mariner of knowing the exact rise and fall, and the times of high and low water, may be appreciated when we consider that the entrances to many rivers and harbors on the Atlantic coast are obstructed by sand bars, which can only be crossed by vessels of more than ordinary draught at the highest stage of the water. It becomes therefore an object of immense importance to commerce and navigation to determine the laws which govern this rising and falling of the sea, and to furnish such rules as will enable the mariner to predict with certainty all the phenomena connected with this subject. There is indeed no subject which is so constantly in a sailor's thoughts, on approaching the entrance to harbors and rivers, as the tides. In many cases the safety of his ship and his life depend upon his precise knowledge of the time of high water, or the ebb and flow of the current. The theoretical solution of this question was one of the first results of Newton's theory of gravitation. The most casual observer may notice the close dependence of the tidal phenomena upon the moon's motion. The wave of high water follows the moon in her motion around the earth by a determinate interval of time; and the height of the tide depends also upon the position of the sun and moon. As the elevation of

the water is produced by the joint attraction of the sun and moon, the height will be greatest, of course, when those bodies are in conjunction, that is, at new and full moon, giving rise to what mariners call spring tides. When the moon is 90° distant from the sun, or in quadratures, the joint effect will be least, and the neap tides will be produced. The discussion of this problem has engaged the attention of the most profound mathematicians since the days of Newton, particularly Laplace; and yet the mathematical theories, although correct, have failed until recently in giving results which have been confirmed by observations. The cause of the discrepancies has existed, not in the mathematical deductions, but in a want of knowledge of the physical geography of the globe, and of the depth and form of the bottom of the sea; and, although very important advances in our knowledge of this subject have been recently made by scientific men both at home and abroad, yet it may be said that it is still one of the most perplexing questions in physical science. Prof. Bache, on assuming charge of the coast survey, organized a system of tidal observations, embracing the entire coast. It is the most extended system of observations that has yet been attempted, and has already produced highly useful results. Of these the most important to mariners is the publication annually by the coast survey of a series of tide tables, by which they are enabled to predict with great accuracy the time and approximate height of the tides at any of our more important harbors for every day in the year. This useful publication has now been in existence for several years, and its advantages to the sailor are almost incalculable. Tidal observers in the coast survey service are required to note hourly the height of the water at each tidal station, by means of a staff placed in the water, by which also the precise times and height of high and low water can be determined. A self-registering machine is also much used, which, through the medium of clockwork, traces a curve on paper representing the successive changes in the height of the water. More than 900 tidal stations have been established on the Atlantic coast; and on the western coast observations have been made at frequent intervals for a distance of about 1,500 miles. The observations at the principal stations are continued through several years. Their investigation of course involves very laborious computations; the great object being to combine their results with theory, in such a manner as to furnish rules for the prediction of future results. The results of this branch of investigation in the survey have been published in the annual reports of the superintendent as the work has proceeded, showing the success which has attended the operation of the system. The report for 1856 contains tables of comparison of predicted tides of Boston harbor with the results of actual observation, in which the predicted times of high water coincide with

the times observed within four minutes. Such accurate results had never before been obtained; and this contribution to knowledge may be regarded as one of the most important of the present day. In the published tables we have the predictions of the height and times of high and low water for over 250 points on the Atlantic coast. On the Pacific coast predictions have been made with equal success for a great number of stations, and these are annually increasing in number. Prof. William Ferrell has developed a new method of calculating tides, of a purely dynamical kind. The method hitherto in use has consisted in supposing the water to be in a state of equilibrium under the attractions of the earth, moon, and sun, and then applying purely empirical corrections to the results so obtained. Prof. Ferrell has taken account of the fact that the water is in motion and has momentum. This was first done by Laplace, but unsuccessfully, because friction was neglected. Ferrell has taken account of this. His theory has been applied by himself, at the desire of the present superintendent of the coast survey, to the case of Boston harbor; and its superior accuracy has thus been demonstrated, as well as its great value in saving laborious calculations of empirical corrections. Prof. Peirce has given much study to the calculation of the effects of friction on tidal currents; and his results, combined with the original observations and researches of Mr. H. Mitchell, have produced a great advance in the theory of this subject, and important practical rules for draining tide lands, &c.—*Figure of the Earth*. The geodetic system of surveying originated in the efforts of philosophers to determine the precise figure and size of the earth. It is well known that the earth is not exactly spherical in shape, but is flattened slightly at the poles of the axis about which it revolves, this axis being about 26 miles shorter than the equatorial axis. The determination of the relative lengths of the earth's axes has been one of the most important physical problems of all ages. The dimensions of the earth are of course essential elements in the mathematical investigations connected with astronomy, and in the computations of trigonometrical surveys. The measurement of extended arcs of meridian and parallel furnish the best means of determining these lengths; and the problem has been considered of so much importance, that expensive expeditions have been fitted out, and surveys made in different parts of the world, for this object alone. But, although approximate determinations have been made, it cannot be said that the dimensions of the earth are definitely settled. The primary triangulation of the coast survey furnishes incidentally valuable contributions to science in this respect. An arc of the meridian 1,500 m. in length has been measured in India, one of 1,800 m. through Russia, extending from the Black sea to the Arctic ocean, and another of 900 m. in France,

from Dunkirk to the island of Formentera in the Mediterranean. Several arcs have also been measured in Germany; and in fact there is hardly a civilized nation that has not contributed its share to our knowledge of this subject. It was in the first attempts to measure the French arc that the science of geodesy originated. In the United States, an arc of the meridian has been measured by the coast survey, between the years 1844 and 1867. It extends from Nantucket in Massachusetts to Farmington in Maine, and is $3^{\circ} 23'$ in length. A second arc is in process of measurement between Ocracoke inlet in North Carolina and the head of Chesapeake bay. The northern part, which extends over Chesapeake bay, was completed in 1871, and is $2^{\circ} 40'$ in length. The total extent of the whole arc when completed will be about $4^{\circ} 32'$. Other arcs will be measured as the geodetic work advances.—*Variation of the Compass.* It is well known that every navigator determines his course and direction by means of an instrument called the mariner's compass, which depends solely upon the direction which a small needle or bar of steel assumes when magnetized and left free to move in any direction. This direction is nearly north and south; and it was formerly supposed that the north end of the needle pointed directly to the north pole of the earth, to which it was attracted by some powerful agent in the polar regions. Continued observation and study of the subject, however, disclosed the fact that this was not true. The real direction of the needle at any point between the equator and the poles is inclined to the horizon, and also to the true meridian; or, in other words, the needle has a dip and a variation or declination. At Key West, for instance, in 1858, the dip of the needle was 55° ; at Cape Hatteras, 68° ; at New York, 73° ; at Halifax, 76° ; while the declination was 5° E. at Key West, and 6° W. at New York; and between these places there is a line where there is no variation from the true meridian. This line passes near Wilmington, N. C., Charlottesville, Va., and Pittsburgh, Penn. Going westward from this line, the declination of the north end of the needle to the east of the true meridian increases rapidly until the Pacific coast is reached, when it is from 15° to 20° E. It is found also that the direction at any one place is not constant, but that it changes not only during each day, but from year to year. In surveyors' and mariners' compasses the dip of the needle is overcome by suspending it from a point above its centre of gravity; but the declination still exists, and gives rise to what is popularly called the variation of the needle. Surveyors on land have generally the means of ascertaining the variation by astronomical observations, by which very great errors in their maps may be avoided; but the common mariner has no such resource. In sailing from the gulf of Mexico to Portland, Maine, his compass would pass through all points from 5° E. to 13°

W. How is he to know this, unless it be put down on his chart? And how will a chart for one year answer for another, when the variation is constantly changing? It is plain that the laws which govern these changes must be found out, so that the changes may be predicted. The determination of these laws, and the actual direction of the needle at various points of the coast at particular times, have occupied the attention of the superintendents of the coast survey. It is impossible to explain here the delicate and laborious nature of the observations necessary for determining the direction and intensity of the magnetic force. The results published by the coast survey have been obtained by comparing the observations of many years with the deductions of theory, and may be said to exceed in importance and usefulness all that had previously been done in this country. From the results of observations made not only on the Atlantic and Pacific coasts, but also in the interior of the continent, a map has been constructed giving the lines across the continent along which the dip is the same, and along which the declination is the same, and corresponding lines for the intensity. From such results the laws are obtained for predicting future changes. From these facts the importance of a full investigation of a subject of such vital interest to navigation may be appreciated. As it forms a part of the duties of the coast survey to furnish the mariner with all the information possible on this subject, it ought not to be neglected even in a brief account of the work.—*Office Work.* The observations and charts made in the field are at the close of each season's work sent to the coast survey office in Washington, where they are combined to form the charts. The triangulation and astronomical observations are subjected to a double computation, first by the observers, and next by the computers in the office, in order to insure perfect accuracy and faithfulness. The topographical and hydrographical sheets are combined, and reduced drawings are made on scales suitable for publication. A connected series of charts of the whole coast is projected on a scale of $\frac{1}{80,000}$. Besides these, local charts of harbors and bays are published on larger scales, adapted to the importance of the locality and amount of detail to be shown. General coast charts are also published on a scale of $\frac{1}{400,000}$. When the reduced charts are drawn and verified, they pass into the hands of the engraving division of the office, where they are executed on copper. When the plates are completed, electrotype copies are taken of them, which serve for printing the charts, the original plates being preserved in the archives. The electrotyping establishment of the coast survey is very extensive, and one of the most successful in the world. It was in practical operation several years before the process came into general use, and considerable advances were made in the art at this establish-

ment. Photography is also employed to reduce the original charts to the scale of the intended publications, and a photographic establishment has long been a part of the office. For reducing maps from one scale to another and transferring their outlines to the engraving plate, an instrument called a pantograph has been for some years employed. This is a repeating machine composed of a number of arms acting upon each other as levers, with points for tracing and engraving, and mounted upon traverse wheels, for ease and accuracy of movement. This instrument can be set to any desired scale, representing the proportion which the map to be engraved bears to the original; and when so set, with the tracing point resting upon the original map and the engraving point upon the plate, if the former be moved over the map, the latter will reproduce upon the plate an absolutely exact copy of the original on the required scale. The advantage gained by dispensing with the old methods of reduction, which required an experienced draughtsman, at great expense, together with the greater accuracy resulting from but one operation in reducing from the original to the plate, is apparent when we consider the usual process of drawing, tracing, transferring, and entering by hand. Here are four distinct operations, each liable to more error than the one operation performed by the pantograph. The charts are finally printed at the office, and distributed for sale to agents in the principal seaports. The prices are fixed at very low rates, so as to place a complete set of charts within the reach of every navigator. Provision has been made by congress for the publication of the observations made in the progress of the survey, so as to place the data on which the correctness of the charts depends beyond the possibility of loss, and to submit them to the criticism of the world. — *Organization.* The operations of field work which have been described are carried on simultaneously at many points on the coast. The Atlantic and gulf coasts are divided into nine, and the Pacific coast into two sections, each having its triangulation, astronomical, topographical, and hydrographical parties, all working independently, but upon the same system; so that, in the end, the whole will form a connected survey from Maine to Texas, and from San Diego to the 49th parallel on the Pacific. Besides these sections, since the acquisition of the territory of Alaska, the coast survey has added that large extent of coast to its already extensive field of operations; and parties have been at work there regularly, carrying on reconnaissance, triangulation, topography, and hydrography, whenever the weather of that stormy region would permit. For conducting these operations there are employed in the coast survey, exclusive of hands and seamen, 94 civilians of different grades, and 11 officers of the navy, a number of the latter being required for vessels engaged in hydrography, which are

under naval discipline. This force does not include computers, draughtsman, engravers, and clerks employed in the office, all of whom number 93. The whole work is under the control of the United States treasury department; while the superintendent directs all the details of the work, governs the movements of the parties, and controls the expenditures. The expense is defrayed from annual appropriations by congress, made upon estimates submitted by the superintendent, which from 1853 to 1858 amounted to about \$200,000 for the Atlantic and gulf coasts, and about \$150,000 for the western coast. Of late years, however, the work has become so much extended, and the labors of the survey so much increased, as to necessitate a much larger expenditure, not a small item in which is the appropriations for new vessels to replace those captured and destroyed during the war, and those which have become worn out by long and arduous service. The progress of the work from year to year is given to the public in the annual reports of the superintendent. In these reports not only the results of the year's operations are given, but also the ways and means by which they are obtained. The liberality of congress in publishing and largely distributing these reports has tended greatly to increase the public interest in the work.—The investigations of the tides, the Gulf stream, the magnetic force of the earth, and the meteorological conditions of the atmosphere, have an equal bearing upon the interests of navigation and commerce and the sciences connected with the physical condition of the globe. But there are other practical results of the coast survey which have a more direct influence in protecting our commerce from the dangers by which it was formerly attended. A consideration of these results will exhibit the advantage of an intelligent application of true scientific principles in all works of this character. Previous to the year 1844, 300 vessels were wrecked annually on our coast, attended with a great loss of life. Of these vessels one sixth were destroyed on the Florida reefs. To illustrate the causes which led to this great loss of life and property, it will only be necessary to mention a few of the discoveries made in the survey of the coast. The position of the entrance to Delaware bay, between Cape May and Cape Henlopen, was found to be eight miles in error. Six dangerous shoals were discovered in one year in the vicinity of Nantucket, lying directly in the track of our European commerce, and of the heavy coast trade between the eastern and southern states. A new channel, with two feet more water than any other, was discovered in the entrance to New York harbor. Dangerous shoals were discovered at the entrance to Chesapeake bay, and along the coasts of Virginia and North Carolina. Innumerable other discoveries of no less importance have been made, but space forbids other mention of them. The few above given are sufficient to

show the inaccuracies of all our charts previous to the investigations of the coast survey. The means that have been applied to correct these great evils have not been incommensurate with the end. It may be said that advantage in economy is not the least of the practical results of the scientific methods of the survey. Compared with foreign surveys, it is not only more accurate in detail, but its results have been produced with a rapidity and economy altogether unprecedented. The English survey was commenced in 1791, and is still unfinished, the land work being as yet unconnected with the hydrography. The cost of that survey is more than four times the cost of ours. During the ten years previous to 1848, Great Britain expended for hydrography alone \$7,500,000. The total cost of the United States coast survey up to that time was only \$800,000, including land work and hydrography. At the present time, while the survey has extended its operations across the whole continent, and even included the distant domain of Alaska, its expenditures, including the cost of building a number of new vessels, have been comparatively small. With this small expense the survey has been extended so as to embrace the whole of our Atlantic, Pacific, and gulf coasts. During the year 1872 12 triangulation parties, 2 astronomical parties, 12 hydrographical parties, and 14 topographical parties were in the field on the Atlantic and gulf coasts, and 13 parties on the Pacific, besides the computers, draughtsmen, engravers, &c., employed in the office. Up to the present time (1873) 1,282 original topographical and 1,144 hydrographical sheets have been surveyed, and charts of 240 harbors on the Atlantic and gulf coasts, and of 100 harbors on the Pacific, have been published, besides 209 coast and sailing charts, great numbers of copies of which have been issued. An elaborate and careful "Coast Pilot" of the Atlantic coast is in process of preparation, and one has already been completed and published for Alaska and the Pacific coast.

COATZACOALCO, or *Coatzacoaleos*, a river of Mexico, rising in the unexplored part of the Sierra Madre, and flowing N. across the isthmus of Tehuantepec into the bay of Coatzacoalco, in the gulf of Mexico, in lat. $18^{\circ} 8' 30''$ N., lon. $94^{\circ} 17' W.$ It is the most important of the streams which water the N. slope of the isthmus, on account both of its numerous tributaries and its extensive basin, and of its position as a part of a projected channel of interoceanic communication. A commission sent out by the United States in 1850 ascended by small boats to the village of Santa Maria Chimalapa, $4\frac{1}{2}$ m. below its junction with the Chimalapilla; and in the winter of 1870-71 it was again explored by a party under command of Capt. R. W. Shufeldt, U. S. N., who demonstrated the practicability of a canal by this route. About 45 m. below Santa Maria it receives the Malatengo on the west, and on the

same side, 22 m. further down, it is joined by the Sarabia. The Jumuapa enters 17 m. below, and next to it the Jaltepec, which is the principal tributary on the west, being navigable by canoes 50 m. at all seasons. The Chalchijapa joins on the east, $22\frac{1}{2}$ m. below the Jumuapa. Thence to the point of Horqueta, $40\frac{1}{2}$ m. further, the affluents are all small. After the junction of the Sarabia the hills become considerable, and below the mouth of the Jaltepec the banks of the river are in few places more than 10 or 15 ft. high, and are often overflowed. The current is scarcely perceptible, and during the dry season shoals are met with having only 18 inches of water over them. At the Horqueta, 102 m. below the Malatengo, the river branches, and after forming the island of Tacamichapa, reunites. The W. branch is called the Mistan, the E. the Apotzongo. The former, which is the longer, is 34 m. long and has an average depth of $13\frac{1}{2}$ ft. The Coahuapa joins the river on the east, 10 m. below the junction of the branches; $4\frac{1}{2}$ m. below its mouth, on the W. bank, is the village of Minatitlan; and $4\frac{1}{2}$ m. below this the river Usapanapan, the most considerable of the many tributaries of the Coatzacoalco, joins it on the east. From the lower point of the island of Tacamichapa to the mouth of the Coahuapa the depth is $26\frac{1}{2}$ ft., and thence to the bar from 33 to 40 ft. The breadth between the same points is from 130 to 700 yards. It is thus navigable for about 35 m. for the largest ships. At the mouth of the river, which lies 115 m. W. of the mouth of the Tabasco, and $143\frac{1}{2}$ m. in a direct line from the harbor of Ventosa, on the Pacific coast of the isthmus, there is a bar, the soundings over which made by order of Cortes in 1520 gave the same results as those obtained in 1850 and in 1871. It appears to be of limestone rock, with a light covering of coarse sand, and has two passes, one 350 ft. wide and 13 ft. deep, and the other 100 ft. wide and between 11 and 12 ft. deep. The breadth of the stream at its mouth is 1,500 ft. Just within the bar is the little village of Coatzacoalco, which has grown up since 1855, and is now frequented by vessels engaged in the mahogany trade.

COBALT, one of the elementary metals. The word cobalt was formerly used to designate a whole group of worthless metals. The superstitious miners imagined that the genii of the mountains resisted all attempts to penetrate their mysteries, and threw all sorts of false ores and unripe metal in the way of the workmen, in order to discourage them from their undertaking. These mountain gnomes or sprites were called kobolds, and the miners gave their name to the worthless ore. The bright shining mineral that vexed the workmen so much was at one time supposed to contain bismuth, and was very little used. These are the first recorded notions, but there is little doubt that cobalt ores were used for coloring glass some thousands of years before in Nineveh, Thebes,

and Pompeii, as specimens found in those places resemble the beads and ornaments of modern times. The first really authentic discovery of cobalt appears to have been made in 1733, by the Swedish chemist Brandt, who called it "cobalt king." Chemical analysis had not at that time attained sufficient progress to enable any one to separate the constituents of ores with absolute certainty, and it was not till 1780 that the existence of cobalt was confirmed by Bergman. Cobalt is one of the metals found in the atmosphere of the sun and in meteorites. It usually occurs associated with nickel, arsenic, and sulphur, and is frequently an incidental product in the working of copper, bismuth, and nickel ores. The best known minerals are smaltine, called also speiss cobalt, cobaline, glance cobalt, cobalt bloom, and earthy cobalt. The fact that some of the minerals contain arsenic has led to the application of the name cobalt to the black arsenic sold as a fly powder.—Metallic cobalt may be prepared from the oxide by heating two parts of the pure oxide of cobalt and one part of pure cream of tartar for six hours in a covered crucible lined with charcoal, and at a temperature sufficient to melt steel. The regulus obtained in this way is exceedingly hard and brittle, has the color of bismuth, is magnetic, and has a specific gravity of 8.43. By remelting in a clay crucible, it can be freed from carbon, and it then has a silver-white color and a specific gravity of 8.754, is softer than steel, very elastic, does not oxidize in air nor after several days' immersion in water, and is as magnetic as iron. Becquerel found that by electrolysis a brilliant white metal goes to the negative electrode when the chloride of cobalt is first neutralized with ammonia. Prepared in this way, it is quite pure, and is malleable and magnetic. By treating an aqueous solution of the chloride of cobalt with sodium amalgam, an amalgam of cobalt is formed, from which the mercury can be expelled, and the cobalt obtained in the condition of a fine powder; it can afterward be fused to a pure regulus. The metal resembles steel with a slight red tinge, is very hard, and is said by Deville to be more tenacious than iron. This latter property may hereafter give a value to wires made of cobalt, where it is required to attain great strength in a small compass. Arsenic and manganese render it brittle. Like pure iron, it requires a very high heat to melt it, and the temperature of fusion appears to be between that of iron and gold. Its specific heat is 0.1096, and its density ranges between 8.513 and 8.7. At a high temperature it burns with a red flame, yielding an oxide. Acids generally dissolve cobalt, nitric acid being especially adapted to this purpose. The metal decomposes water at a red heat, but not at ordinary temperatures. Plunged into fuming nitric acid, it is converted into the passive state, the same as iron, and the duration of this passive state is augmented

by previously heating the metal. Antimony and cobalt fused together evolve heat and light, and afford an iron-gray alloy. The alloy of cobalt and iron is exceedingly hard. Gold and cobalt yield a yellow and very fragile alloy. The alloy of platinum and cobalt is fusible. Cobalt amalgam is white, like silver, which is rendered brittle by it. Alloys of lead and cobalt and tin and cobalt have been made, but possess little interest. Many chemists suppose nickel to be an alloy of cobalt and some other metal. Fairbairn found that the tenacity of cast iron was greatly reduced by its admixture with nickel, and the same result is probable in the case of cobalt. The latter metal is said to reduce copper from solutions. Weiske found that cobalt was contained in nearly every brand of commercial iron examined, sometimes to the extent of 7 grammes in 100 pounds. Finely divided metallic cobalt is soluble in a boiling solution of caustic potash, and yields a blue liquid, which is supposed to contain cobaltic acid. The finely divided cobalt for this purpose is prepared by heating an intimate mixture of pure oxide with 10 to 12 per cent. of starch meal, or by reducing the oxide with hydrogen. Cobalt contaminated with phosphorus has a different color from ordinary metal, and loses its lustre in the air.—The oxides and salts of cobalt are distinguished for their beautiful colors, red, blue, yellow, and green; hence they were early used as pigments. If a little oxide of cobalt be added to melted glass, we obtain a mass which after cooling is intensely blue. When this is ground to powder, it yields the well known smalt, which at one time was extensively employed by paper makers and in the laundry. The color is very fast, as it is not affected by the atmosphere, or by acids or other liquids; and this fact afforded a method of detecting adulterations, as sand or pulverized glass which was simply immersed in some coloring liquid could easily be washed clean by acid. Since the extensive and cheap manufacture of artificial ultramarine was established, the demand for smalt has greatly diminished. There is another blue color formed by the union of alumina and the oxide of cobalt, known as Thénard's blue, which has long been applied in the arts, but, in consequence of its high price, cannot compete with ultramarine. It can be prepared by mixing 3 parts freshly precipitated moist phosphate or arsenate of cobalt with 12 to 15 parts, also freshly precipitated, of hydrate of alumina, and exposing after drying to a red heat. Thus produced, it is a compact insoluble mass, which can be ground to a fine blue powder. Rinmann's green is a compound of the oxides of zinc and cobalt. It is a much prized green pigment. A beautiful yellow color is produced by mixing the nitrate of potassium with a solution of cobalt; a double nitrate of cobalt and potash is produced, in the form of an insoluble yellow crystalline body, which is not only of value as a color, but of-

fers a remarkably delicate test for the presence of cobalt in solutions. This yellow has been used sparingly, on account of its cost, in aqua-relle and oil painting. By precipitating cobalt with phosphate of soda, we have a red-violet color, the shade of which varies according to the temperature at which it is prepared. A fine cobalt brown is produced by calcining a mixture of sulphate of cobalt, ammonia, and iron. Some of the salts of cobalt are red when they contain water, and blue when they are anhydrous. This property is made use of in what is called sympathetic ink. If we write with a dilute solution of chloride of cobalt on paper, and allow the tracings to dry at ordinary temperatures, the letters will be scarcely visible. Upon the application of heat the writing becomes visible, with a blue color, or sometimes green if nickel be present; the color again disappears on the absorption of moisture. A fine green color is produced by precipitating cobalt from its solutions, by means of a mixture of prussic acid and potash; but the cost of production must prevent any extensive application of this color. Since the discovery of photography, the use of cobalt-blue glass has greatly increased. It is an interesting fact in optics that blue glass permits all the chemical rays of light to pass freely through it, while the yellow are intercepted. Pieces of blue glass are used to eliminate the yellow rays when the colors of flames are to be examined for the violet hue of potash, and in other cases of optical research. The oxide of cobalt, prepared by precipitating the chloride with potassa, has been employed in rheumatism; it is emetic in doses of 10 to 20 grains. The salts of cobalt are irritant poisons. The employment of metallic cobalt in the manufacture of German silver would make that article too expensive for general use; but in small quantities it enters into alloys, in association with nickel, as an incidental component. The deposition of metallic cobalt by the battery can be accomplished the same as is now so extensively done with nickel, and this method is sometimes employed to procure small quantities of the metal. Some of the salts of cobalt are of great value to the chemist in his laboratory, as affording delicate tests for the presence of other bodies. One of the methods for the manufacture of oxygen from bleaching powders is founded upon the somewhat obscure formation and subsequent decomposition of cobaltic acid. A very small quantity of a solution of cobalt suffices to evolve all of the oxygen from a given quantity of chloride of lime. The ammoniacal compounds of cobalt were prepared and fully studied by Genth and Gibbs. The nitrate of cobalt is sometimes employed as a reagent for the blowpipe. The compounds of cobalt are easily recognized by the intense blue color which they communicate to a bead of borax in the oxidating flame. Zaffre or safflor is a mixture of roasted ore and quartz, used in pottery.

COBAN, a city of Guatemala, capital of the department of Vera Paz, on the left bank of the Rio Dulce, near its source, in lat. 15° 30' N., lon. 90° 30' W., 55 m. N. of the city of Guatemala; pop. about 15,000. It is situated in a remarkably fertile valley, covered with thriving plantations of sugar cane, bananas, and pimento and fruit trees. The inhabitants, chiefly Indians, are industrious and wealthy.

COBB, a N. W. county of Georgia, bounded S. E. by the Chattahoochee, and drained by several creeks; area, 529 sq. m.; pop. in 1870, 13,814, of whom 3,217 were colored. The surface is hilly, and in part mountainous. The soil is fertile. The rocks are granitic and metamorphic, and produce gold. The Western and Atlantic railroad intersects the county. The chief productions in 1870 were 58,296 bushels of wheat, 215,522 of Indian corn, 23,182 of oats, 130,650 lbs. of butter, and 1,972 bales of cotton. There were 893 horses, 799 mules and asses, 1,784 milch cows, 3,035 other cattle, 2,843 sheep, and 10,897 swine; 2 manufactories of cotton, 1 of woollen goods, 1 of paper, 2 wool-carding and 3 leather-carrying establishments, 1 flour mill, 4 saw mills, and 4 tanneries. Capital, Marietta.

COBB, Howell, an American politician, born at Cherry Hill, Ga., Sept. 7, 1815, died in New York, Oct. 9, 1868. He graduated at Franklin college in 1834, and was admitted to the bar in 1836. In 1837 he was elected by the legislature solicitor general of the western circuit. He began his congressional career in 1843, having been elected to the house of representatives, in which by three successive reëlections he sat till 1851. He was distinguished for his familiarity with the rules of the house, his skill as a debater, his strong professions of attachment to the Union, and his equally earnest advocacy of state rights. He became the leader of the southern party in the house, and upon the assembling of the 31st congress in December, 1849, he was elected speaker after a violent contest. He demanded the extension of slavery into California and New Mexico by federal authority, and supported the compromise measures of 1850. In 1851 he was elected governor of Georgia, defeating the candidate of the extreme southern rights party, which opposed the compromise. At the expiration of his term in 1853 he resumed the practice of the law, but in 1855 was again elected to congress, and in 1856 made a tour through the north to support the election of Mr. Buchanan. In March, 1857, he became secretary of the treasury in President Buchanan's cabinet, and held that office till Dec. 10, 1860, when he resigned to engage in the secession movement. In February, 1861, he became president of the confederate congress assembled at Montgomery, Ala., and afterward transferred to Richmond, but retired Feb. 18, 1862, on account of misunderstandings with Jefferson Davis. Subsequently he was commissioned a major general, but took little part in military

movements. After the close of the war he continued hostile to the reconstruction policy of the government. He died suddenly of heart disease, while on a visit to New York.

COBBE, Frances Power, an English authoress, born in Dublin in 1822. She is of English extraction, her father having derived his estates from his great-grandfather, Charles Cobbe, who was archbishop of Dublin. Her attention was early directed to theological studies, and after a wide course of reading she became deeply interested in the writings of Theodore Parker. Upon the death of her mother, which occurred while she was still young, she made inquiries of Parker in regard to a future existence. His reply was contained in his "Sermon of the Immortal Life." She became his warm friend and admirer, and edited the excellent English edition of his works. After her father's death she visited Italy and the East, and as the fruits of her travels wrote "The Cities of the Past" and "Italics" (London, 1864). On returning to England she assisted Miss Mary Carpenter for a time in the Red-house reformatory. Her labors were soon discontinued in consequence of an accident, but they furnished her with the materials for several papers upon the condition of the poor and friendless, which, after appearing as pamphlets and in magazines, were published with other essays under the title of "Studies New and Old of Ethical and Social Subjects" (1866), and "Hours of Work and Play" (1867). In 1860 she made a second visit to Italy, and was with Theodore Parker at Florence during the last days of his life. Since his death she has been an earnest exponent of his religious ideas. Besides contributing largely to various periodicals, in some of which her sympathy for the United States during the civil war was manifested, she has written much on moral and religious subjects. In "Broken Lights" (1864) may be found a statement of the doctrines of the different divisions of the English church, and also a discriminating view of the writings of Renan. In her "Essay on Intuitive Morals" (1859), perhaps her ablest production, she controverts with great force of reasoning the utilitarian theory of ethics as set forth by its English advocates. Her book entitled "Religious Duty" (1865) may be considered as a sequel to this essay. Her latest work, entitled "Darwinism in Morals, and other Essays" (London, 1872), treats of unconscious cerebration, dreams, and other questions of psychology. Miss Cobbe's present residence (1873) is in London, where she holds a prominent place in philanthropic and reformatory movements, as well as in literature.

COBBETT, William, an English political writer, born at Farnham, in Surrey, March 9, 1762, died near Farnham, June 18, 1835. His father, who for many years kept an inn at Farnham, and farmed a piece of land in the neighborhood, taught him reading, writing, and arithmetic, and employed him in the fields

from early boyhood. At the age of 20 he vainly endeavored to enter the navy. In the following year he made his way to London, where he became copying clerk in an attorney's office, which employment he found so irksome that he enlisted in the 54th infantry regiment in 1784. He was sent to Chatham, where he remained for a year, during which time he read much, studied grammar, and rose to the rank of corporal. Accompanying his regiment to New Brunswick, his good conduct during the following three years was such that at the age of 25 he was promoted, over 30 sergeants, to the rank of sergeant major. The regiment returned to England in 1791, after which at his own request he obtained his discharge, with excellent testimonials from his superior officers. On Feb. 5, 1792, he married at Woolwich the daughter of a sergeant major with whom he had been acquainted in New Brunswick. Soon afterward they went to France, but on account of the revolution returned to England in six months, and soon sailed for the United States. At Philadelphia, under the name of "Peter Porcupine," he wrote several political pamphlets in favor of England, and opposed to French principles. He opened a shop for the sale of his own compositions, among them one attacking Dr. Rush, who brought a suit, and obtained a verdict of \$5,000 damages. In 1800 Cobbett returned to London, opened a book shop in Pall Mall, published the "Works of Peter Porcupine" in 12 volumes, and established a daily paper called "The Porcupine," in which he supported Mr. Pitt's administration. This journal was short-lived, and on stopping it Cobbett commenced the "Weekly Political Register," the publication of which was continued without interruption till his death. The sale of the "Register" became so large that Cobbett was soon enabled to acquire Botley, a large farm in Hampshire, where he resumed a country life, giving a few hours daily to his editorial duty. He was prosecuted and convicted for various libels on the government and individuals. In July, 1810, he was convicted of a libel for denouncing the flogging of English militiamen by German soldiers, and sentenced to two years' imprisonment in Newgate, with a fine of £1,000. The money was raised by subscription, but he had to suffer the full sentence of imprisonment; and though he continued to write in prison (among other productions, his famous currency book, "Paper against Gold"), his income suffered greatly. In 1816 he began an occasional publication called "Two Penny Trash," whose sale rose to 100,000 copies. Its influence with the working classes was so great that the "six acts" were passed in 1817 for the express purpose of preventing public meetings, and of silencing the independent press. Cobbett retreated to the United States, dating his subsequent "Registers" from Long Island, where he leased a farm, until the repeal of the particular statute which he feared might be put in

force against himself. Returning in December, 1819, he added more to his notoriety than popularity by bringing with him the bones of Thomas Paine. He had formerly denounced Paine as a regicide and infidel, and now urged the English people to give him a grand funeral and a splendid monument. In 1820, during the prosecution of Queen Caroline for adultery, Cobbett is said to have been her secretary, writing her replies to addresses, as well as her celebrated letter to the king. He now took a farm at Kensington, where he cultivated American trees and plants, Indian corn included, which he thought might be useful to England, and to which he tried to give the name of "Cobbett's corn." In the following ten years he wrote many books, each of which obtained a large sale. Most remarkable among these are his "History of the Protestant Reformation in England and Ireland," with such a Roman Catholic bias that it has been translated into French and Italian; English and French grammars, written with great clearness; "Advice to Young Men and Women," containing many charming passages of autobiography; "Treatise on Cobbett's Corn;" "Emigrant's Guide;" "Cottage Economy;" "Village Sermons;" "A Year's Residence in America;" "History of England," &c. He also edited various other books. Early rising, temperate living, concentrated industry, and health preserved by much outdoor exercise, enabled him to get through a greater quantity of brain work than any other author of his day, Scott not excepted. Besides the weekly writing of his "Register," he compiled 20 volumes of parliamentary debates. He strongly condemned the currency views of Peel, and as strongly advocated Catholic emancipation, granted in 1829, and parliamentary reform, completed in 1832. In July, 1831, while the reform excitement was agitating England, the whig ministry brought Cobbett to trial for what the attorney general (Denman) described as a seditious libel, exciting agricultural laborers to destroy corn, machinery, and other property. Cobbett, who conducted his own defence, made a very damaging attack on the whig government. After 15 hours' deliberation, the jury, equally divided in opinion, could not give a verdict, and were discharged, which ended the trial. At Coventry in 1820, and at Preston in 1826, Cobbett had unsuccessfully attempted to be returned to parliament. In December, 1832, chiefly through the influence of Mr. John Fielden, a resident wealthy manufacturer of that borough, he was elected for Oldham, when 70 years old. In the following session he moved resolutions on the currency, in which there was offensive mention of Sir Robert Peel. Not only was his motion negatived, but the commons ordered the resolutions to be discharged from their minutes. He made no impression in parliament, and had no influence. At the general election in December, 1834, he was again returned to parliament

for Oldham. Unaccustomed labor, performed at late hours in a heated atmosphere, soon told upon a man far advanced in age, whose previous boast had been that he rose at 4 and went to bed at 9. He had a sudden attack of disease of the heart during a debate on the malt tax, on May 25, 1835, was removed to his country residence near Farnham, and survived only three weeks. He was buried in the churchyard of his native town, by the side of his father and mother. In 1856 a tomb was erected over the slab which had hitherto covered his grave. As a politician Cobbett was unstable and inconsistent, but always wrote with great power. As an author he stands very high. Southey declared that there never was a better or more forcible English writer. In public his pen seemed almost against every one. In domestic life he was a faithful husband and most affectionate and indulgent parent. In 1842 his son published, in six volumes, with notes, a selection from Cobbett's political works. In 1848 this was extended to nine volumes.—See "Biographies of John Wilkes and William Cobbett," by the Rev. John Watson (London, 1870).

COBDEN, Richard, an English statesman, born at Dunford, near Midhurst, Sussex, June 3, 1804, died in London, April 2, 1865. On the death of his father, a small farmer, he was taken charge of by his uncle, a warehouseman in London. Before he entered business on his own account he saw much of England as a commercial traveller, visiting also Egypt, Turkey, and Greece in 1834, and the United States in 1835. By this time he had become partner in a cotton-printing establishment near Manchester, and built up a prosperous business. In 1835 he pronounced the leading address at the opening of the Athenæum of Manchester, which he had helped to establish. He also published two pamphlets, "England, Ireland, and America, by a Manchester Manufacturer," and "Russia." In the latter he questioned the extent of the vast resources generally attributed to Russia. In 1837, after having unsuccessfully contested the representation of the borough of Stockport, Mr. Cobden visited France, Belgium, and Switzerland. In 1838 he travelled through Germany, and on his return strongly declared in favor of free trade. In 1839, when the house of commons rejected a motion for the repeal of the bread tax, Mr. Cobden took a leading part in establishing the well-known and powerful anti-corn-law league. He was elected for Stockport in 1841, and immediately obtained a high place among the leading parliamentary speakers, from his oratorical ability and from the great extent and variety of his knowledge upon all subjects connected with trade and commerce. He spoke and voted in parliament for the repeal of the corn laws, and spoke and lectured in most of the counties of England on the same subject. Meanwhile the anti-corn-law league grew into power and popularity, strengthened

with vast funds raised by the free-traders. Sir Robert Peel finally became a convert to the necessity of a change, and, with much opposition from the agricultural interest, succeeded in procuring the passage of the memorable act for repealing the duties on the importation of corn, to which the royal assent was given June 26, 1846. Driven out of power immediately after by a hostile vote on his Irish policy, Peel took leave of office in a speech which contained a handsome acknowledgment that the repeal of the corn laws was chiefly attributable to Mr. Cobden. National gratitude shortly after presented Mr. Cobden with a substantial pecuniary acknowledgment, raised by subscription, to the amount of £80,000, on the receipt of which he retired from business, and purchased the property near Midhurst on which he had been born, and which his family had formerly owned. While absent in 1846-'7 on a continental tour through France, Spain, Italy, Germany, Russia, and Sweden, he was reelected member of parliament for Stockport, and also for the West Riding of Yorkshire. He decided to sit for the great county rather than for the small borough. He was reelected in 1852. As an active member of the peace society, he had advocated the propriety of deciding national disputes by arbitration rather than by arms, and had published several pamphlets strongly urging these views. He discountenanced the war with Russia, which his constituents supported. In 1857 he was one of the majority which passed a vote of censure on Lord Palmerston for entering into the war with China, which caused his rejection by the electors of the West Riding. Soon afterward he went abroad, and spent nearly two years on the continent and in the United States. During his absence he had been returned to parliament from the borough of Rochdale, and upon his return in 1859 he was informed that Lord Palmerston had offered him a seat in his cabinet as president of the board of trade. This office he declined, on the ground that his views had always differed so much from those of the premier that he could not consistently serve in his cabinet. In 1860, however, he consented to act as commissioner in negotiating a treaty of commerce with France, in which he was entirely successful. This treaty was regarded as a great triumph of diplomacy, but it was abandoned by the French in 1872. Mr. Gladstone, speaking in 1866, said in regard to it, "I don't believe that the man breathed upon earth at that epoch, or now breathes upon earth, that could have effected that great measure, with the single exception of Mr. Cobden." After the negotiation of the treaty he was offered a baronetcy and a seat in the privy council, both of which he declined. The frail state of his health prevented his taking so active a part in public affairs as he had formerly done; nevertheless, he made occasional speeches in parliament, urged the repeal of the paper duty as a tax on knowledge, and the re-

duction of the national expenditure, particularly in the military and naval departments. He was always the earnest and consistent friend of the United States, never lost faith in the cause of the Union during the civil war, and vigorously opposed all schemes for recognizing or aiding the confederacy. Mr. Cobden was, with John Bright, a leader of the Manchester school or party, and, besides the measures above alluded to, favored electoral reform and the vote by ballot. A marble statue of Cobden has been erected in the town hall of Bradford at the expense of Mr. Booth, an American merchant of that town. His works have been collected under the titles of "Political Writings of Richard Cobden" (2d ed., London, 1867), and "Speeches on Questions of Public Policy," edited by Bright and Rogers (1870). His biography has been written by J. McGilchrist (London, 1865), and in German by Von Holtzendorff (1866) and De Roth (1867).

COBI, Desert of. See GOBI.

COBIJA, or Puerto la Mar, the only seaport town of Bolivia, capital of the department of Atacama or Cobija, on the Pacific coast, in lat. 22° 32' 50" S., lon. 70° 17' 5" W., 365 m. S. W. of Potosi. The town is on the beach, at the foot of a range of high hills. On a point jutting into the sea is a small fort, mounting five or six guns. The harbor affords good anchorage, but landing is difficult on account of the surf. Efforts have been made to improve it of late by the erection of a mole. The town is a wretched place, composed of a few wooden houses, the principal of which are on a street running N. and S. along the shore. Water is scarce and of poor quality. The port is free, and is much visited by vessels of various nations, as it is the chief outlet for the exports of the country, and through it the southern provinces are supplied with foreign commodities. The only road from the seacoast to the interior in Bolivia is that from this port to Oruro, and it is constantly traversed by beasts of burden, bringing coin, bullion, ore, and other products from the interior, and carrying imported goods inland. A railway to Potosi has been planned, and if built will add greatly to the prosperity of the place, which is dependent on the mines. These mines, which are chiefly of silver and copper, are mostly in the hands of English capitalists, who import everything used by them.—Until 1829 Cobija was a mere fishing village, inhabited by Indians. It was made a free port in that year, and in 1839 it became the capital of the department. In 1855 it had a population of about 600, which had grown in 1858, in consequence of increased activity in mining, to 2,300. It has now about 2,500 permanent residents and a floating population of as many more. In official documents the town is called Puerto la Mar.

COBLENTZ (Ger. *Coblenz* or *Koblenz*; anc. *Confluentes*), a fortified city of Prussia, capital of the province of the Rhine, at the confluence of the Rhine and Moselle, 49 m. S. E. of Co-

logne; pop. in 1871, exclusive of the garrison, 24,528. A Gothic freestone bridge of 14 arches, erected in the 14th century, crosses the Moselle; and one of boats, across the Rhine, leads to the fortress of Ehrenbreitstein, on the E. bank. There is also an iron railway bridge across the Rhine, built in 1866. The fortifications are constructed partly on the system of Vauban, partly on that of Montalembert, and are capable of accommodating 100,000 men, and the magazine will hold provisions for 8,000 men

for ten years. Among the public buildings, the church of St. Castor is notable as the place where in 843 the grandsons of Charlemagne met to apportion the empire. An active trade is carried on in colonial produce, corn, iron, potters' clay, mineral waters, bark, and chiefly sparkling Rhine and Moselle wines. Manufactures also flourish to some extent. The city consists of the old and the new town, the latter being the more pleasant. The palace in the new town, a royal summer residence, is a

Railway Bridge between Coblenz and Ehrenbreitstein.

fine structure, erected about 1780 by the last elector of Treves; it was for some time used by the French as a barrack. The Protestant church has some fine specimens of early painted glass. The casino contains an elegant ball room and good reading rooms. There is a hospital conducted by the sisters of charity, and a town library, with valuable collections of coins, paintings, and antiquities. The environs of Coblenz embrace some of the finest scenery of the Rhine valley. During the French revolution the *émigrés* made their headquarters at Coblenz; many of them settled permanently in the town, which consequently contains more infusion of French blood than perhaps any other Rhenish town. Prince Metternich, Prof. Görres, and Henrietta Sontag were born in Coblenz.

COBOURG, Canada. See COBURG.

COBRA DE CAPELLO (hooded snake), the Portuguese name of the *naja tripudians* (Merr.), a venomous serpent of the East Indies, so called from its habit of dilating the neck into a kind of hood, covering in part the head; it has also received the name of spectacle snake, from the peculiar coloration on the back of the dilated hood. The family to which this serpent belongs seems to establish the transition between the genus *coluber* and the true venomous serpents; for, though armed with poisonous fangs, they have not the external characters of *trigonocephalus*, *crotalus*, and *vipera*, such as heavy forms, large triangular heads, and carinated scales; on the contrary, the form is slight and graceful, the head small and rounded, and the scales smooth; like *coluber*, they have the top of the head covered with nine plates. The

poison apparatus is less developed than in the rattlesnake, and its excretory duct is shorter and unfolded; the long processes of the vertebrae are smaller and indicate less muscular strength than in the true venomous serpents; the bones of the head are less movable; the

Cobra de Capello:

fangs are fixed in the jaws, which are capable of only moderate extension; and the whole aspect indicates a gentleness and docility which it is well known they possess. The cobra de capello has been known for centuries as possessing the power of dilating its neck, which is marked in a peculiar manner, and as being the dangerous playmate of the Indian jugglers.

The dilatation of the neck depends on the length and straightness of the ribs of this part; at rest, they are directed backward, but when drawn forward they assume a horizontal direction, and thus spread laterally the integuments of the neck; this dilatation extends from the head to about the 10th vertebra, gradually dimin-

ishing upward and downward from the middle of this space. This power of dilatation is possessed by many other serpents to a less degree. The two white spots with a black centre, united in front by a curved line, are rarely so distinct as to resemble spectacles, being generally irregular black marks which the imagination could transform into a great variety of semblances; they are most distinct when the hood is dilated, and are probably due to the arrangement of the scales consequent on the forced raising of the ribs. Two spots are sometimes seen on the lower surface of the neck. These colorations are not sexual differences, as they occur both in males and females. The general color of this serpent is a brownish yellow, of various degrees of brightness; the young often have the body with black bands and white spots. The total length is from 3 to 4 ft., and the thickness a little more than an inch; the tail is short, robust, and conical; the trunk is cylindrical and strong, as indicated by the agility of its movements. When attacked it raises itself boldly, supporting the trunk on the tail placed horizontally on the ground; then, with body bent, dilated neck, and threatening head, it presents quite a formidable appearance. It devours toads, frogs, birds, small animals, and also other snakes. In confinement they often utter a peculiar cry, described by a traveller, in whose apartment one of these snakes was catching rats at night, as a "strident sound, the attempted imitation of which resembled the acute staccato note of a treble hautboy." This species is found throughout the East Indies, and on many of the islands of the Indian archipelago, varying somewhat in color according to locality; it is nocturnal in its habits, and very frequently enters houses in search of its prey. The specific name *tripudians* (dancing) given to it by Merrem indicates a frequent use made of it by the Indian jugglers, to the great surprise of the uninitiated; the poison fangs are first extracted, so that their bite is quite harmless, though the exhibitors pretend to employ powerful antidotes; the serpents are trained to execute certain movements corresponding to the motions of the jugglers, keeping time to the musical accompaniment, and resembling a rude dance. The poison of the cobra, though less virulent than that of the rattlesnake, is exceedingly dangerous; from the experiments of Dr. Russell, in his work on the serpents of India, it appears that its poison proves fatal to a dog in less than 27 minutes, and to a chicken in less than half a minute; inserted by incision or inoculation, it is equally dangerous. Unless remedies are speedily applied, the bite of the cobra is generally fatal to man. According to Dr. Davy, its poison has an acrid taste, paralyzes the iris of fowls when applied to their eyes, and is soon exhausted by biting; it produces fainting, coldness, convulsions, and death, the lungs being generally found gorged with blood and serum. After the mechanical means of removing the poison have been tried,

such as ligatures above the wound to prevent the return of venous blood, sucking the bitten part, excision, cauterization, or the application of cupping glasses, the constitutional remedies are, in the first place, diffusive stimulants, to support the prostrated nervous energy which invariably accompanies such bites; such are ammonia alone, or, as *eau de luce*, in combination with tincture of oil of amber, or even simple alcoholic stimulants in large and repeated doses, which have been found to prevent the fatal effects of the more virulent poison of the rattlesnake. The favorite remedy in the East Indies is arsenic, either in the famous Tanjore pills, each of which contains about one grain of arsenic, or in Fowler's solution, which contains the arsenite of potash; experience has shown the efficacy of the pills in some cases reported by Dr. Russell, where no other remedy was employed, and they might prove as beneficial in the bites of other venomous serpents. This cobra has received a number of native names, one of the most common of which is *goomna*. Several interesting experiments with the poison of the living cobra, some made in Boston in 1871, are given in the "Proceedings of the Boston Society of Natural History," vol. xiv. Such is the rapidity with which the poison is introduced into the blood that antidotes are rarely of any avail, though the fatal result may not occur for several hours. The cobra avoids using its fangs as much as possible except when securing its food, and rarely if ever bites unless trodden upon. The idea that the poison of the cobra has no effect upon the mongoose, or that the latter if bitten finds an antidote in certain plants, is entirely erroneous; the mongoose, if bitten, dies as soon as any other animal; the fact is that this agile creature avoids the bite of the sluggish reptile, and always seizes it by the back of the head, destroying it instantly. The cobra exhibited in Boston had eaten nothing for seven months, and yet seemed in good condition.—The *N. haje* (Linn.), found in Egypt and also in southern Africa, has sometimes been erroneously called cobra de capello, which might lead to the supposition that the true serpent of this name extended its area of distribution into Africa. (See Asp.)

COBURG. I. A duchy of Germany, forming with Gotha the united duchy of Saxe-Coburg-Gotha, one of the states of the empire; area of Coburg alone, 218 sq. m.; pop. in 1871, 51,709. (See SAXE-COBURG-GOTHA.) II. The capital of the duchy, and alternately with Gotha the residence of the duke and seat of government of Saxe-Coburg-Gotha, situated on the Itz, 185 m. S. S. W. of Berlin; pop. in 1871, 12,819. The streets are generally narrow, but there are some pleasant public walks. There are five Protestant churches and a Roman Catholic chapel, a gymnasium, an orphan asylum, an institution for the deaf and dumb, three hospitals, and a public library of 26,000 volumes. The Ehrenburg palace, one

of the residences of the duke, built in 1549, has a picture gallery, valuable collections of engravings, coins, antiquities, and minerals, and a library of 27,000 volumes. The government house is a handsome structure in the Italian style. There are a town hall, arsenal, theatre, and riding school. On an eminence overhanging the town is an ancient castle of the dukes of Coburg, now in part converted into a prison and house of correction; but some of the chambers remain in their original condition, among them those occupied by Luther when concealed in the castle, where he com-

part of Wallachia, including Bucharest. In the wars with France in 1793 and 1794 he took a successful part, defeating the French at Neerwinden and capturing Condé and Valenciennes, but eventually he was defeated at Maubeuge and Fleurus.

COBURG FAMILY, a family of sovereign German dukes, originating in the 15th century, now celebrated for intermarriages with European royal families. A sister of Duke Ernest I., who died in 1844, was the duchess of Kent, mother of Queen Victoria; and his brother Leopold, whose first wife was a daughter of George IV. of England, and his second wife a daughter of Louis Philippe, became the first king of the Belgians; while Albert, son of Duke Ernest I., and brother of the reigning duke of Coburg, Ernest II., was the consort of Queen Victoria. One of the nephews of Ernest I., Ferdinand, was consort of the queen of Portugal, and after her death (1853) for some time regent of the kingdom; and another, August, married Marie Clémentine, a daughter of Louis Philippe, while his niece, Victorie, became the wife of the duke de Nemours.

Grand Ducal Palace, Coburg.

posed some of his best works, and in which are his bedstead and pulpit. During the thirty years' war the castle was unsuccessfully besieged by Wallenstein. Coburg has several dye works and breweries, and some manufactures of potash, glass, cotton and woollen goods, and toys.

COBURG, a town of Northumberland co., Ontario, Canada, on Lake Ontario and the Grand Trunk railway, 63 m. E. N. E. of Toronto; pop. in 1871, 4,422. It is the capital of the united counties of Durham and Northumberland; is lighted with gas, has an artificial harbor, and a town hall, with county and town offices. Victoria college, having university powers, is situated here, the faculty of law being at Montreal and that of medicine at Toronto. It is the terminus of the Coburg, Peterboro', and Marmora railway company, on which much iron ore is carried for shipment. In summer the lake steamers call here daily. The exports in 1871 amounted to \$436,988; imports, \$95,770.

COBURG, or **Saxe-Coburg**, **Josias**, prince of, an Austrian field marshal, born Dec. 26, 1737, died Feb. 26, 1815. In 1788 he commanded the Austrian army against the Turks, and after the conquest of Khotin, and the victory at Fokshany, he entirely routed the Turks near Martinestie, and took possession of the larger

COBWEB, the delicate silken thread woven by the spider, and applied to various uses by the different species. Some form of it webs in which to entangle their prey, others use it as a lining for their habitation, and others make with it a soft nest for their eggs. Each thread which we see with the naked eye is formed of thousands of minute strands, which, coming separately from the body of the spider, unite at a short distance from it, not by twisting, but by their glutinous nature. The webs of different species of spiders are of various construction, adapted to the nature and habits of the creature. Some are very remarkable for their tenacity, being sufficiently strong to catch small birds. Sir George Staunton, in his "Embassy to China," states that spiders' webs are met with in the forests of Java of so strong a texture as to require to be cut through with a knife. In the "American Journal of Science," vol. xxvii., p. 307, is an account of a live striped snake suspended in a web by the tail, which was tied in a knot. Three spiders appeared to have accomplished this feat, having spun a cord of great size to connect the snake with the centre of the web above; they had also securely tied up the mouth of the reptile by a multitude of threads wound around it.—Cobwebs have been applied to various uses. The delicate

cross hairs in the telescopes of surveying instruments are fine webs taken from spiders of species that are especially selected for their production of an excellent quality of this material. The spider, when caught, is made to spin his thread by tossing him from hand to hand, in case he is indisposed to furnish the article. The end is attached to a piece of wire, which is doubled into two parallel lengths, the distance apart exceeding a little the diameter of the instrument. As the spider hangs and descends from this, the web is wound upon it by turning the wire round. The coils are then gummed to the wire and kept for use as required. About a century ago, Boa of Languedoc succeeded in making a pair of gloves and a pair of stockings from the thread of the spider. They were very strong, and of a beautiful gray color. Other attempts of the same kind have been made; but Réaumur, who was appointed by the royal academy to report on the subject, stated that the web of the spider was not equal to that of the silkworm either in strength or lustre. The cocoons of the latter weigh from three to four grains, so that 2,304 worms produce a pound of silk; but the bags of the spider when cleaned do not weigh above the third part of a grain, so that a single silkworm can accomplish the work of twelve spiders. It has been said that the spider web is beneficial in intermittent fever, asthma, and hysteria; but careful modern observation has not confirmed the statements heretofore made as to its extraordinary therapeutic virtues.

COCA, the dried leaf of the shrub *erythroxylon coca*, or, as in Prescott's "Conquest of Peru," "*erythroxylum Peruvianum*, or *cuca*, as called by the natives." This plant is found wild in the mountainous regions of Peru and Bolivia, and

Coca.

is cultivated in districts elevated from 2,000 to 5,000 ft. above the sea. It is valued for its stimulating narcotic properties, which it is said to possess in a greater degree than opium, to-

bacco, or any other vegetable production. The leaves are gathered and dried in the sun, and are chewed mixed with quicklime, which the Peruvians affirm renders its flavor sensible to the taste. As described by Pöppig (*Reise in Chile, Peru, &c.*, vol. ii., 1835), the practice of chewing the leaf is attended with the most pernicious consequences, producing an intoxication like that of opium. As the indulgence is repeated, the appetite for it increases, and the power of resistance diminishes, until at last death relieves the miserable victim. He describes the aroma exhaled from heaps of freshly dried leaves as so powerful in its effects, that persons unused to its properties suffer from severe headaches if they fall asleep near them. Prescott speaks of the coca as an article of so invigorating a nature that "with a small supply of it in his pouch, and a handful of roasted maize, the Peruvian Indian of our time performs his wearisome journeys, day after day, without fatigue, or at least without complaint." Under the incas it is said to have been exclusively reserved for the noble orders. The statement of Mr. Whittall, R. N., made public by Dr. Thomson, in his "Cyclopædia of Chemistry," confirms the account of its giving wonderful powers of endurance, the Indians under its influence working 20 and 30 hours together without sleep. They travel on foot from La Paz to Sucre, 70 leagues, in three days, consuming little food, but chewing constantly the coca, carrying it in a small bag over their shoulder, together with a bottle of quicklime. The miners of this country, mostly Indians, are furnished with provisions by their employers, everything, excepting coca, in limited quantity; of this they are supplied with all they want. Some consume of it a pound a week, worth 6 reals (75 cents), or, if cultivated by the proprietors, about 4 reals. Its infusion has been used as a substitute for tea, enough for half a dozen people being made with four or five leaves. These are first treated before steeping with a little hot water, to draw off the acidity.

COCCEJUS, Johannes, a German Hebraist, whose real name was Cock or Koken, born at Bremen in 1603, died in Leyden, Nov. 4, 1669. At first professor of Hebrew at Bremen, then of Hebrew and theology at Franeker, he finally became professor of theology in Leyden, and wrote voluminous commentaries on the Bible, and numerous other works. He was the founder of a mystical sect who assumed the name of Cocceians.

COCCIA, Carlo, an Italian composer, born in Naples in 1789, died in Milan in 1873. He studied under eminent masters, became professor of music in Naples, and was connected as composer and director with theatres in Lisbon, London, and Turin. His productions include over 60 operas, more or less remarkable for exquisite melody. The most popular of them were *La festa della musica*, *Clotilda*, *La selvaggia*, *Fayel*, and *Maria Stuart*. He produced his last work in 1846.

COCCOLITHS AND COCCOSPHERES, names given, the former by Prof. Huxley, the latter by Dr. Wallich, to minute rounded bodies adherent to the gelatinous submarine protoplasm to which Prof. Huxley gave the name of *bathybius*. (See BATHYBIUS.) The latter are larger and more complex in structure than the former. The coc-

Coccoliths, magnified.

coliths he subdivides into discoliths and cyatholiths. He describes the discoliths as oval discoidal bodies with a thick, strongly refracting rim, and a thinner central portion, the greater part of which is occupied by a slightly opaque cloud patch, corresponding to the inner edge of the rim, from which it is separated by a transparent zone; in general, they are slightly convex on one side and correspondingly concave on the other, and the rim is raised on the more convex side; they are about $\frac{1}{8000}$ of an inch in their longest diameter. The cyatholiths are like minute shirt studs, varying in size from $\frac{1}{8000}$ to $\frac{1}{8000}$ of an inch. Coccospheres are described as of two types, one compact, the other loose in texture; the largest of the former type being about $\frac{1}{13000}$, and those of the loose type $\frac{1}{7000}$ of an inch in diameter; they seem to be made up of bodies resembling cyatholiths; in fact, Dr. Wallich believes that the coccospheres are the parents of the coccoliths; both, without doubt, are the calcareous hard parts belonging to bathybius. These bodies have been found fossil in the chalk, showing the close resemblance of the conditions under which the chalk beds were formed to those existing at the bottom of the present Atlantic ocean.

COCCULUS, the fruit of a climbing plant, called by Linnæus *menispermum cocculus*, but

Cocculus Indicus.

now referred to a new genus, *anamirta*, imported from the East Indies. It is about the

size of a pea, and somewhat resembles the bayberry, having a dry, wrinkled exterior coat, within which is a shell enclosing a bitter, oily kernel. The bitter principle, called picrotoxin, is extracted by triturating the seeds with pure magnesia, and treating them with hot alcohol. To obtain it pure, it is again dissolved in alcohol, and treated with animal charcoal. After proper evaporation, it is deposited in crystalline form. In India, in Europe, and in the United States the *cocculus Indicus*, ground into a coarse powder, is used to intoxicate fish that they may be more easily caught. It is sometimes added to malt liquors, to increase their stupefying qualities. It is never given internally, but an ointment made from it is used in the East Indies as an outward application in obstinate cutaneous eruptions. A strong tincture of the fruit, rubbed upon the scalp of a child, has been known to produce fatal results.

COCHABAMBA (*cocha*, a lake, and *pampa*, a plain). I. A department of Bolivia, bounded by La Paz, Beni, Santa Cruz, Chuquisaca, and Oruro; area, 26,808 sq. m.; pop. about 380,000. It includes almost every climate, perpetual snows covering the mountains on its N. border, while the sugar cane and cacao grow to perfection in its rich valleys. Gold and other minerals exist, but mining receives little attention. The principal productions are cotton, sugar, dyewoods, and timber. It is divided into the provinces of Cochabamba, Sacaba, Tapacari, Arque, Ayopaya, Clissa, and Misque. The province of Cochabamba occupies a great plain at the foot of the snowy mountains, the passes leading to it being nearly 15,000 ft. high. This plain is cultivated throughout, and is very productive, the vegetation, which resembles that of the south of France, consisting wholly of imported species. II. A city, capital of the department and province, situated at the E. end of an extensive plain, 8,370 ft. above the sea, 122 m. N. N. W. of Sucre; lat. 17° 27' S., lon. 65° 46' W.; pop. about 40,000. It is built on both banks of the Rio de Rocha, which, as well as the Tamborada joining it just below, generally overflows in the rainy season, but is nearly dry during the rest of the year. The houses, mostly of but one story in height, are surrounded by gardens, and the city consequently covers much space. In the centre is a grand plaza, around which are four churches and the *cabildo* or government house, the latter a large plain building. There are in all 15 churches. The streets are broad and well kept, but the squares, used as market places, are generally littered with wares and goods and crowded with Indians. The prevailing language is the Quichua; good Spanish is spoken by persons of rank only. Cochabamba, situated in a comparatively isolated valley and devoted to agriculture, has not only escaped the decline which has overtaken most of the other Bolivian towns, but has continued to prosper and increase. It has considerable manufactures, particularly of

cotton cloths. Glass ware is made also to some extent. In 1579 Cochabamba, then recently founded, was named Oropesa by the viceroy of Lima, and the name is sometimes found in maps and documents, but is now unknown in Bolivia. The women of the place distinguished themselves by their daring and patriotism in 1815, during the war of independence.

COCHET, Jean Benoit Désirée, abbé, a French archæologist, born at Sanvic, near Havre, March 7, 1812. He studied at the college of Havre and at the seminary of Rouen, took orders in 1836, and became vicar at Havre and Dieppe, and subsequently almoner of the lyceum at Rouen. In 1842 he discovered at Étretat the remains of a Roman villa, and afterward made various explorations in the neighborhood of Dieppe, bringing to light many remarkable antiquities. Besides papers in several journals, he has published *Églises de l'arrondissement du Havre* (2 vols., 1844-'6); *Églises de l'arrondissement de Dieppe* (2 vols., 1846-'50); *Étretat, son passé, son présent, son avenir* (1852); *La galerie dieppoise* and *La Normandie souterraine*, the latter work crowned by the institute (1854); *Sépultures gauloises, romaines, franques et normandes* (1857); *Églises de l'arrondissement d'Yvetot* (2 vols., 1862); and *Répertoire archéologique du département de la Seine-Inférieure* (1872).

COCHIMI, a nation of Indians in Lower California, occupying the district between lat. 25° and 33° N., with some islands. According to their tradition, they were driven southward by other nations after a general war. The Cochimis, including the Laymones, were the most populous of the California tribes. They were darker in color than the Indians of Mexico, and well formed, but in the lowest degree of savage life, rising somewhat however above the other Lower Californians, being more intelligent and less brutal. The Jesuits began missions among them at San Ignacio in 1706, and maintained them till the suppression of the order, when they were continued for a time by the Dominicans. They were taught to cultivate the soil, and until the mission system was broken up by the Spanish government they were self-supporting and prosperous, but have since declined greatly.

COCHIN. **I.** A rajahship of India, near its S. extremity, on the Malabar coast, intersected by lat. 10° N., bounded N. by the district of Malabar, S. by Travancore, and W. by the Indian ocean; area, 1,988 sq. m.; pop. about 300,000. A considerable portion of the territory is under the presidency of Madras, and the remainder is governed by a rajah, under the protection of and tributary to the British. Magnificent forests of teak, ironwood, jackwood, and ebony cover the higher grounds, and are the source of most of the revenue of the country. The narrow valleys in the N. portion are well watered and fertile, yielding two crops of rice annually. There are several generally well

built and cleanly Christian villages, while near the town two classes of Jews, the Jerusalem or white Jews, and the ancient or black Jews, are numerous. **II.** A town, capital of the British district, and formerly of the rajahship, 168 m. N. N. W. of Cape Comorin, and 350 m. S. W. of Madras; pop. about 20,000. It is situated on a low sandy flat on the Malabar coast, and is nearly insulated by a backwater, extending S. to N. about 40 m. The harbor is obstructed by a bar, which prevents vessels of over 400 tons from entering at high tide. The port is also seriously affected by the S. W. monsoon for several months in the year, during which vessels can neither enter nor depart in safety. The town is a mile in length and half a mile in width, with streets crossing each other at right angles, and houses generally two stories high and covered with tiled roofs. The arsenal is the principal building. The fine cathedral built by the Portuguese was converted by the Dutch into a warehouse for the Dutch East India company. The suburbs Gulvaty and Mattuncherry extend half a mile S. E. along the edge of the backwater, and are inhabited by the white and black Jews, each class having a synagogue. Ship building, formerly the most important interest of the town, is still carried on to some extent, and timber, cocoanuts, coconut oil, coir, cordage, and cassia are the chief exports.—In 1503 the Portuguese were permitted to build a fort here. They established a Roman Catholic bishopric, which has long been vacant. The native Christians belong partly to the sect called the Christians of St. Thomas, and partly to the Roman Catholic communion; but they are described as grossly depraved and superstitious. The Dutch captured the town in 1663, made it the capital of their Indian settlements, and under their sway it became populous and thriving. The British took it in 1795, and in 1806 levelled the ramparts and blew up the fortifications and many of the public buildings, the explosion shattering nearly all the private dwellings of any size and value. Those of the Dutch who had means left the town, but most of them were reduced to beggary. A few Dutch families still reside there, and there is an old Dutch church in the N. W. part of the town, in which a Protestant minister officiates.

COCHIN, Charles Nicolas, a French engraver and designer, born in Paris in 1715, died April 29, 1790. He was hardly less eminent as a man of letters than as an artist, and published several volumes of travels and art criticisms. His engravings, numbering upward of 1,500, are executed with great taste and skill.

COCHIN, Pierre Suzanne Augustin, a French writer, born in Paris, Dec. 12, 1823, died at Versailles, March 15, 1872. He early took part in many philanthropic societies, and in 1850 became deputy to the mayor of the 10th arrondissement of Paris, and in 1853 mayor. Afterward he was a member of the municipal commission of the Seine. He was a strong

but unsuccessful candidate in the elections of 1863, 1869, 1870, and 1871. In 1871 he was one of the commission of inquiry as to the administration of Paris and the department of the Seine; and he was appointed by Thiers prefect of the department of Seine-et-Oise, but declined. He wrote upon social charity and political economy in the *Annales de la charité* and the *Correspondant*, of which he was from 1845 a leading editor. His *Essai* on Pestalozzi gained honorable mention in 1848 from the academy of moral and political sciences, to which he was elected in 1864; and his *Abolition de l'esclavage* (1861) received a prize of 3,000 francs from the French academy. Other important works are his *De la condition des ouvriers français* (1863), *Le monde invisible* (1864), and *La réforme sociale en France* (1865).

COCHIN CHINA. I. A province of the kingdom of Anam, occupying a narrow strip of its eastern coast, extending from about lat. 11° 30' to 17° 30' N. Its greatest length is a little more than 400 m.; greatest breadth not more than 70 m.; area, about 27,000 sq. m.; pop. estimated at 1,000,000. The general features of the country and its population are described in the article ANAM. This province formerly gave its name to the whole kingdom, but with the wider knowledge gained by Europeans of the Indo-Chinese peninsula, the more correct title of Anam superseded that of Cochin China, which is now, since the capture of Lower Cambodia by the French, almost exclusively applied to that region. The Anamese province is becoming better known under its native name of Dang-Trong. The principal town, Hué, is the capital of the whole kingdom. II. **French or Lower Cochin China**, a French colony in the southern part of the Indo-Chinese peninsula, bounded N. W. by Cambodia, N. E. by Anam, E., S., and S. W. by the China sea and the gulf of Siam; area, 21,724 sq. m.; pop. in 1868, 1,204,287. It consists of six provinces, Bienhoa, Saigon, Mytho, Vinhlong, Chandoc, and Hatien, the first three of which were ceded by Cambodia to France by the treaty of June 5, 1862, and the rest were declared French territory by the proclamation of Admiral de la Grandière, June 25, 1867. The physical features of the country, the character of its inhabitants, and the few known events of its history previous to the war which ended in French dominion, are described in the article CAMBODIA. Its more recent history is briefly as follows. After repeated instances of persecution on the part of the Anamese, who then ruled Cochin China, against the Christian missionaries, especially those of France and Spain resident in Lower Cambodia, and after repeated attempts on the part of the French to force upon the government the toleration of Christianity, a more serious conflict than had before occurred took place in 1847, originating in the attempt of Thien-tri, the king then reigning, to entrap and capture several French naval officers by treachery. Capt. Lapiere attacked

Turon with two ships of war and destroyed its fortifications, about 1,000 Anamese falling in the encounter. For several years after this an unfriendly state of affairs existed between the French and the king Tu-Duc, who scornfully refused in 1856 to make a treaty. This continued till 1857, when the murder of the Spanish bishop Diaz (July 20) was the signal for the outbreak of actual war. Admiral Rigault de Genouilly, with some aid from Spanish troops sent from Manila, again attacked Turon, took the peninsula of that name, penetrated early in 1859 into the interior of the country, by the river, and on Feb. 17 captured the port of Saigon. The French were preparing to push their conquests further, and Page, Rigault de Genouilly's successor, had already taken possession of several points near the coast, when the war in China called away their forces and determined them to hold only Saigon. It was not till February, 1861, that they were able to again begin operations on an extended scale. Admiral Charner then arrived with a large force from China, defeated the chief division of the Anamese army on Feb. 25, and within the next year was in possession of three important towns, Mytho, Bienhoa, and Vinhlong, and in a position to compel the submission of all lower Cochin China. Under the pressure of these circumstances, Tu-Duc found himself compelled to abandon a portion of his territory to save the rest, and on June 5, 1862, he made peace by a treaty in which he gave up the three provinces of Bienhoa, Saigon, and Mytho, and the island of Pulo Condore, to the French, promised tolerance toward the Christians, opened the Anamese ports of Turon, Balat, and Quangan, and bound himself to pay an indemnity of 20,000,000 francs. This treaty was concluded with Admiral Bonard, who had succeeded to the command of the French forces in August, 1861, and who was at once made governor of the colony. Vice Admiral de la Grandière succeeded him on May 1, 1863. On Aug. 11 of that year he concluded a treaty with the king of Cambodia, by which that country was placed under the protectorate of France, and by which the king gave up to the French the important river town of Namwang or Panomping, on the Mekong. In 1863 revolts against the French rule broke out in Gocong, south of Saigon, and in the spring of 1864 in Baria, and later in other parts of the country. Assuming that these disturbances were incited and promoted in the three provinces that still remained under the control of Anam, Admiral de la Grandière in 1867 declared it necessary to punish their inhabitants and government; and with this transparent cover for a scheme of further conquest, he took possession with a large force of these three provinces also, meeting with little or no resistance from the people.—The colonial government of Cochin China is now under the immediate control of the French ministry of marine, which appoints a governor of the

country, who is assisted by a council of which the commander of the French forces and an official corresponding to the American secretary of the interior are the chief members. The affairs of the provinces are managed by *inspecteurs des affaires indigènes*, under the last named officer; but with the local and municipal governments the French have interfered but little. The governor's residence is at Saigon, which has been greatly improved, and raised to a port and naval station of much importance.—See Aubaret's *Histoire de la Basse-Cochinchine* (Paris, 1867); Taillefer's *La Cochinchine, ce qu'elle est, ce qu'elle sera* (Périgueux, 1865); Lemire's *Cochinchine française et royaume de Cambodge* (Paris, 1869).

COCHINEAL (*coccus cacti*; Span. *cochinilla*), an insect used as a dye. Other species of the same genus of hemipterous insects, of the barklouse family, have been used from the remotest periods to afford the material of the brilliant

1. Cochineal Insects on branch of Cactus. 2. Female Insect. 3. Male Insect.

scarlet and crimson dyes of the ancient Hebrews, Egyptians, and the people of other eastern nations. The *coccus ilicis* is one of these, still found in the Levant, Greece, Palestine, Persia, &c., on a species of oak, in which countries it is employed as it was before the time of Moses. It has long been known by the name of kermes, which came from the Arabs, and signifies red dye. Beckmann conceives that the ancients obtained a finer color from these insects than from Tyrian purples, and its introduction among the Romans caused the use of the latter to be abandoned. The name cochineal, which Beckmann suggests is the diminutive of the Spaniards for *coccus*, is limited to that species which came to the notice of Europeans soon after the conquest of Mexico. The Spaniards found it in high estimation among the natives, who "took infinite pains to rear the insect on plantations of the cactus; and it formed one of the staple tributes to the crown from certain

districts." The Mexican coccus was soon introduced into Europe, where its superior quality was immediately appreciated. Even the live insects were imported, and plantations of cactus were cultivated for their nourishment. The French and Spanish kermes, which at that time was in high repute, disappeared and was soon entirely forgotten. In the family *coccidae* the insects have the form of oval or rounded scales, which cover the stems, branches, and sometimes the leaves of plants. The males, winged, pass through the usual changes, but the females increase only in size, always retaining the scale-like form.—The *coccus cacti* is a small insect with the body wrinkled transversely; its abdomen of a deep mulberry color, and bristly in the posterior part; the legs are short and black, the antennæ subulate and about one third the length of the body. The male has two erect wings, the female none. In Mexico they are reared chiefly in the state of Oajaca, those of the district of Mestique being considered the best insects. There are plantations of the nopal (*opuntia cochinellifera*) upon which they feed, the insects being tended with care equal to that ordinarily bestowed upon silkworms. Before the rainy season sets in, branches of the nopal covered with insects are cut off and brought under shelter to protect them from the weather. At the close of the wet season, about the middle of October, the plantations are stocked from these supplies by suspending little nests made of some soft woody fibre, each containing eight or ten females, upon the spines of the nopal. The insects, warmed by the sun, soon emerge and lay their eggs, each female producing more than 1,000 young. These spread rapidly over the plants, and as the young females become impregnated they attach themselves to the leaves and swell to great size, presenting the appearance more of vegetable excrescences than of animated creatures. In this condition they are gathered for the cochineal. The males, which are few in number, not more than one to 100 or 200 females, are of no value for this purpose. The females are picked off with a blunt knife, the first crop about the middle of December, and subsequently several more of as many successive generations, the last being in May. A laborer can pick off only about enough to make two ounces of cochineal in a day. Those taken off full of young lose about two thirds of their weight in the process of drying, to which they are subjected as soon as they are killed, which is done either by dipping them in a basket into boiling water, or placing them in a hot oven or on plates of hot iron. By the first method, usually considered the best, the insects turn to a brownish red color, losing a portion of the white powder with which they were previously loaded between the wrinkles of the body. In the oven they retain this, and their color is then gray. Those killed on hot iron turn black. Such is the origin of the different varieties known in our market as "silver grains" and

“black grains,” and the “foxy” of the London market, the last being those killed by boiling water, though others ascribe it to the former being the female before laying her eggs, and the latter after she has parted from them. The quality of the cochineal is the same in both cases. When dried, the cochineal presents the form of grains, convex on one side and concave on the other, about one eighth of an inch in diameter, with the transverse wrinkles still visible. It is stated that it takes about 70,000 insects to weigh a pound. In 1866 England imported 32,757 cwt., valued at £594,818, and exported 21,238 cwt., the annual consumption being about 12,000 cwt.; the price in 1870 was about 3s. per pound, a little more than half its former rate. In 1871 the imports into the United States were 1,849,842 lbs., valued at \$1,184,255; of which 800,995 lbs. were from England, 736,573 lbs. from the United States of Colombia, 184,615 lbs. from Mexico, 100,675 lbs. from the West Indies, and 26,989 lbs. from other countries. An inferior quality of cochineal, called *syloester*, is collected from a wild species of cactus, though the insect is sometimes cultivated with the others. Cochineal insects are attacked and fed upon by birds, mice, and the larvæ of other insects; the last named suck out their bodies, leaving only the skin.—Attempts have been made with some success to introduce the culture of cochineal into other countries. The English government at one time offered £6,000 to any one who would introduce it into India. The Spaniards, however, for a long time took every precaution to prevent the removal of the living insects from the country. They were introduced into the Canary islands about 1830, and after the failure of the grape in 1850 became the principal article of export. In 1856 the exports were about 1,500,000 lbs.; in 1870, 6,000,000 lbs., valued on the spot at \$3,200,000, most of which was sent directly to England. The French had succeeded in 1844 in establishing cochineal plantations in Algeria, and specimens have been produced from that country said to be superior to the best Mexican. The Dutch have also succeeded in producing large quantities of genuine cochineal in Java. A variety found in California has all the properties of the cochineal of Brazil and the southern part of Mexico, the only apparent difference being that the article found in California is a light pink, while that of other regions is a deep scarlet.—The coloring principle which causes cochineal to give a crimson color to its watery infusion has been separated by Dr. John, who gave it the name of cochiniline. It is a brilliant purple red color, very soluble in water and in alcohol, but insoluble in ether, obtained by macerating cochineal in ether, and treating the residue with alcohol, and evaporating. It is next to be purified from fatty matters which accompany it by dissolving again in alcohol, and adding a little sulphuric acid, which causes it to be precipitated in a few days. The coloring matter is thrown

down by different metallic salts, as those of zinc, bismuth, iron, nickel, tin, &c., and thus produces precipitates of various brilliant colors. By means of the chloride and nitrate of tin the bases of the splendid crimson and scarlet dyes are obtained, to which the great value of cochineal is chiefly owing. (See CARMINE.) The best of the pigments called lakes are made by introducing freshly prepared gelatinous alumina into the decoction of cochineal.—The high price of cochineal has led to the substitution of other articles in dyeing, and lac and madder have superseded its employment to a great extent. Various articles are used in the adulteration of this substance. Powdered talc or carbonate of lead shaken in a bag with the insects adheres to their bodies, and increases their weight. Grains of a substance manufactured from colored dough have been prepared in France to imitate the dried insect.

COCHITUATE LAKE, a small sheet of water in the towns of Wayland, Framingham, and Natick, Middlesex co., Mass., 17 m. W. by S. of Boston, which is supplied from it with water. It covers 650 acres.

COCHRANE, Lord. See DUNDONALD, earl of.

COCHRANE, John Dundas, a British traveller, nephew of Archibald, ninth earl of Dundonald, born about 1780, died in South America, Aug. 12, 1825. He entered the British navy at the age of 10, and rose to the rank of captain. In 1815 he commenced a series of journeys on foot through France, Spain, and Portugal. In 1820 he submitted to the British admiralty a plan for exploring the interior of Africa and the course of the Niger, which was declined. Cochrane then resolved on making a tour of the globe, as much as possible on foot, his means not allowing him to travel otherwise, intending to cross from Asia into America at Behring's strait. He started from London in February, 1820, reached St. Petersburg April 30, and left that place May 23, the Russian government affording him various facilities. Before reaching Novgorod he was attacked by robbers and plundered of everything, even his clothing. The governor of Novgorod reimbursed him for these losses. He visited Moscow and Kazan, crossed the Ural mountains, halted for a time at Tobolsk, and ascended the Irtysh as far as Semipalatinsk. Thence he turned his steps to Tomsk, and afterward to Irkutsk; there embarking on the Lena, he reached Yakutsk Oct. 6, 1820. From this place he struck out north, continuing his journey on a sledge drawn by dogs; the thermometer often descended as low as -29° F., and on Dec. 31, the day that he arrived at Nizhni Kolymsk, it went down to -62.5° . The Tchuktchis would not allow him to traverse their country on his way to Behring's strait, and he took a S. E. direction, reaching Okhotsk June 23, 1821, after suffering intensely from cold and hunger. For 400 m. he had not met a single human being. On Aug. 24 he set out for Kamtchatka, and on arriving at

Petropavlovsk was well received by the Russian functionaries. There he became enamored of the daughter of the sexton of the town, married her, and abandoned the intention of walking across the North American continent. He returned to London by the same route which he had previously travelled, and reached Britain after an absence of three years and two months, and published "Narrative of a Pedestrian Journey through Russia and Siberian Tartary, from the Frontiers of China to the Frozen Sea and Kamtchatka" (2 vols., London, 1824). His propensity to wander did not allow him to remain quiet long, and he next proceeded to South America, where he died engaged in some mining enterprises.

COCHUT, André, a French publicist, born in Paris in 1812. He early acquired distinction as a political economist and as an authority on Algerian colonization, by his disquisitions in the *Revue des Deux Mondes*, and in 1848 by his *Rapport général sur l'Algérie*, drawn up and printed by order of the government, though the publication was prevented by the outbreak of the revolution. In 1851 he published a volume containing a number of his contributions to the press, especially to the *National*, under the title of *Les associations ouvrières*, &c. His principal subsequent essays are a historical sketch of the system of Law (in the *Bibliothèque des chemins de fer*, 1853), and *Opérations et tendances financières du second empire* (in the *Revue des Deux Mondes*, 1868).

COCK (Lat. *gallus*), a gallinaceous or rasorial bird of the order *gallinæ* and family *phasianidæ*, originally a native of Asia. The birds of this genus, which includes the numerous varieties of domestic poultry, are distinguished from the pheasants by the crown of the head being naked, and the skin raised into a fleshy comb; by the base of the lower jaw having fleshy lobes or wattles; and by the tail, composed of two planes of feathers folded at a sharp angle, being generally carried erect. In the males the central tail feathers are elongated, and fall gracefully over the rest; the feathers of the neck, lower back, and tail coverts are very full, and assume various shapes. They inhabit the jungles of India and the Asiatic islands; they are polygamous, and the males are exceedingly pugnacious, manifesting their joy when victorious by loud and piercing notes; the males have a brilliant plumage, but the females, or hens, are of a duller color and smaller size. Of the many native species now known, it is difficult to decide from which, if from any, the domesticated races have sprung. It is the prevailing opinion that many species have mixed to produce the common barnyard fowls. Temminck, who has paid the most attention to this subject, gives the preference to the species *G. giganteus* and *G. Bankiva*, from the fact that the females of these resemble in form and structure of the feathers our domestic hens, and that the males resemble

the dunghill cock in the great development of comb and wattles. The Jago and the Javan cock are probably the principal wild originals of the domestic breeds; and it is universally admitted that Asia was the primitive seat of the genus, and there also now exist the above mentioned wild species. The Jago cock (*G. giganteus*, Temm.), of large size, is a native of Sumatra and Java; the comb is thick, slightly raised, and truncated or rounded at the top; the throat is bare, and the wattles of moderate size; the head, neck, and upper back are covered with pale golden-reddish hackles; the middle of the back and lesser wing coverts are deep chestnut, the feathers with disunited webs, the hackles covering the rump and base of the tail reddish yellow; tail large, and, with the greater wing coverts, glossy green; secondaries and quills with the outer webs pale reddish yellow; under parts glossy blackish green, with the base of the feathers deep chestnut, occasionally mottling the under plumage. The height of the cocks is from 2 to 2½ ft. To this species must probably be referred the large varieties so well known under the names of Chittagongs, Shanghais, Cochin Chinas, and Brahmappootras. The Javan cock (*G. Bankiva*, Temm.), the type of many of the smaller varieties, and especially resembling many bantams, occurs wild in Java and Sumatra. The skin is bare around the eyes and throat, the comb is large and deeply serrated, and the wattles well developed; the head, back, sides of the neck, and rump are covered with long golden hackles; the upper back is bluish black, the centre of the lesser wing coverts of a deep chestnut, with the webs of the feathers disunited; the greater coverts steel-blue, the secondaries the same, margined with chestnut; the quills brownish black, edged with reddish yellow; the tail black, with metallic reflections; the under parts black. Other wild species, less resembling the domestic fowls, but readily crossing with them, are the following: The bronzed cock (*G. æneus*, Cuv.), also from Sumatra, larger than the Javan; the comb is very large, and not serrated; the wattles are small and thick, and with the bare cheeks and throat are bright red; the feathers are not hackled, of a metallic green, with brilliant reflections; the plumes are rich purple, with a broad pale lake border; the tail is purple, with green reflections; under parts deep black, shaded with purple and green. The fork-tailed cock (*G. furcatus*, Temm.), a native of Java, a large species, is remarkable for its horizontal and forked tail, its smooth comb, and a large single wattle springing from the centre of the throat and divided into several lobes; the feathers of the head, neck, and upper back are short and rounded, close, velvety, and scale-like; the color of the centre is a deep metallic blue shading into golden green, with a narrow border of deep black; on the lower back and tail coverts the feathers are

lengthened, black in the centre, with a narrow edge of yellow; the wing coverts are bordered with orange-red; the under parts are deep black; the hanging tail feathers are metallic green, tinged with steel-blue; the bill, legs, and feet are yellow; the female has much brown in the plumage, and the under parts gray. This species inhabits thick woods, and is very wild; though rarely domesticated, the males cross readily with domestic hens, and in this way add a puzzling element to the problem of the origin of the common races. Sonnerat's wild cock (*G. Sonneratii*, Temm.) inhabits the high wooded districts of Hindostan, where it is called by the English sportsmen jungle fowl. It is nearly as large as the domestic fowl, though of more slender proportions; the comb is large and serrated, and the wattles double; the shafts of the hackled feathers, of a golden orange color, in the centre and at the tip are developed into flat horny plates, similar to those of the wings and tail of the Bohemian

Sonnerat's Jungle Fowl (*Gallus Sonneratii*).

wax-wing; the centre of the back, the throat, breast, belly, and thighs are deep gray; the tail a rich green; below the hackles the feathers are deep purple with a pale yellow edge, and below these golden green, edged with gray with brilliant metallic reflections. The hen has neither comb nor wattles, and the neck is covered with feathers; the plumage is of a general brown tint above, and grayish white below. Though smaller than game cocks generally, it is very bold and active, and is eagerly sought after by the Mohammedan natives of India for cock-fighting; it is generally believed that this species has not mixed with the domestic races, except in the breeds kept as game cocks. The negro cock (*G. morio*, Linn.), originally from India, is remarkable for its blackish violet crest and wattles, black skin and periosteum; the plumage is of a dark color, with bronzed reflections; this easily becomes domesticated, and crosses readily with other races. The crisped

or Friesland cock (*G. crispus*, Linn.), considered a distinct species by Temminck and Gray, has the ends of the feathers turned up or frizzled; it is of small size, wild, not very easily domesticated, and is seldom reared except for curiosity; the pure breed is white, with smooth feet. They are quite common in Java, Sumatra, and the Indian archipelago, where the natives rear them. Some authors consider this and the next species mere varieties produced by accident, and perpetuated by accident or design. The silk cock (*G. lanatus*, Linn.) has the webs of the feathers so disunited that they appear like silk or glossy hairs; the general color is white, and the legs are feathered externally to the toes. It is common in China and Japan, where specimens are sold to Europeans as curiosities. The epidermis is black, and this peculiarity is communicated to the hybrids produced by them and the common fowl, with which they readily cross; the flesh, however, as in the negro fowl, is white and of excellent flavor. The gallinaceous birds are remarkable for the facility with which different species will unite and produce fertile offspring, a peculiarity which renders them doubly valuable to man. The wild hens do not vary in their plumage like the domestic, but resemble each other individually, being generally of colors intermediate between black and white, these two colors being the result of special care on the part of man to keep breeds unmixed. There are species, however, which must originally have been white, as the *G. crispus* and *G. lanatus*, and such breeds will remain white if not crossed with others.—It would be useless to enter into any description of the external appearance of the common cock and hen; but there are some points of internal structure which may be mentioned. Toward the lower part of the neck the œsophagus is dilated into a first digestive cavity with membranous walls, the crop, in which the food remains a certain time and undergoes a partial softening; below this is a second digestive cavity, small in the *gallinae*, but large in birds having no crop, and secreting a gastric juice; this opens into the third stomach, or gizzard, where chymification is completed; the gizzard is remarkably muscular, and able to comminute the hardest food, and even foreign bodies exposed to its continued action; to assist in breaking up the hard grain and seeds on which they feed, the *gallinae* are in the habit of swallowing small pebbles. The intestinal canal is long, as in vegetable feeders generally, measuring five times the length of the bird; the cæca are six inches long; the testes are probably larger in proportion to the size of the body than in any other bird; the trachea and larynx are capable of being elongated, compressed, or dilated, according to the sounds to be produced. The cock is a proud bird, walking as if conscious of his superior strength; but at the same time he is kind, always inviting his family to eat first of any food he may have

discovered, and protecting them from the attacks of all enemies. Now and then a hen essays to crow, but she is generally a barren and useless fowl, despised by her associates and the pest of the farm yard. The cock is very pugnacious, and will always measure his strength with one of his own sex; this propensity is noticed in very young specimens. The male begins to propagate at about the age of three months, and his vigor lasts about three years, though he may live to the age of ten; one is sufficient for 15 or 20 females. The cock is a very clean bird, and spends much of his time in arranging his feathers; his voice, if not soft and melodious, is clear, sonorous, and exhilarating. The cock was a favorite bird with the Greeks and Romans, and is frequently represented on their coins; the ancient philosophers dedicated it to Apollo, Mercury, Mars, and Æsculapius, and thought it the most acceptable sacrifice they could offer to their deities; in later times, the crowing of the cock was supposed to be the signal at which all spirits, whether good or evil, must retire from mortal sight. Like other domesticated races, cocks and hens are very liable to monstrosity; double-headed and four-footed chickens are common in collections. Hens, if properly housed, will lay even in the coldest weather in temperate regions; having laid 18 or 20 eggs, they show a disposition to sit upon them, but if the eggs are taken away they continue laying. As the *gallina* can eat without assistance as soon as they leave the egg, instinct teaches the hen to lay as many eggs as she can cover and keep warm with her body. Like all birds, the hen, if left free to act, will lay her eggs and hatch her brood in some hidden place, and return to the poultry yard with her chickens in excellent condition. The young leave the egg on the 20th day. The affection of the hen for her young is remarkable; as the cock is a model husband and father, the hen is the pattern of a tender and faithful mother.—For epicurean purposes, man has from ancient times been in the habit of removing the testes of the cock; this mutilation renders the birds, called capons, indifferent to sexual and fighting propensities, and causes them to grow fat, with all the whiteness, tenderness, and delicacy of a chicken; the voice loses its shrillness, and their whole demeanor renders them liable to the insult of both cocks and hens, and they require special protection that they may eat, drink, sleep, and grow fat. Capons may be taught to perform some of the offices of the female; they have been taught to hatch out eggs by covering them with their bodies, and to take the care of the young brood. Hens are sometimes deprived of their ovaries, and the flavor of their flesh is said to be thereby much improved.—Various artificial processes of incubation have been tried; the ancient Egyptians were peculiarly successful in their processes, and their hatching ovens furnished in old times 100 millions of chickens annually; other nations,

the French particularly, have invented various kinds of hatching apparatus. By the Egyptian process more than two thirds of the eggs produced chickens, while the hen, upon an average, cannot hatch more than half of the eggs.—Domestication has produced many changes in the form and size of the cock, especially in the crest, wattles, and arrangement of the feathers on the body and legs. The game cock stands at the head of the domestic varieties, from which it does not appear to differ except in its superior strength and courage; the best breed is generally believed to be the *G. Bankiva* without any crossing with other varieties; the East Indians prize the *G. giganteus* and the *G. Sonneratii* as game cocks. Cock fighting was practised among the Greeks and Romans, and was introduced into England by the latter nation, and it is a favorite sport in the East Indies and in Spanish America. In this sport the plumage is trimmed, to make the bird lighter and more active and give its antagonist less hold upon

Game Cock.

it; the legs are armed with an artificial steel spur, called a gaff or gaffle, capable of inflicting a speedily fatal wound. When cock fighting was the favorite sport of kings and nobles, as much attention was paid to keeping the breed pure as was bestowed upon the race horse. The game cock is valuable, independently of his courage; the hens are small eaters, good layers, determined sitters, strong, rarely sick, and very solid and heavy.—Preëminent among the modern favorites are the large Malay and Chinese varieties, embracing the Chittagongs, Shanghais, Cochin Chinas, and Brahmappootras, which are probably all varieties of the *G. giganteus*, variously crossed. The Chittagongs were originally brought from Malacca; they stand high on their legs, are long-necked, and are usually dark brown, streaked with yellow or white; they present a very striking appearance, and form an excellent cross with the common fowl, possessing the hardiness of the latter with the large size of the foreign stock. The Shanghai variety weigh as much when

five months old as the full-grown common kind; they may be black, yellowish, or white, bare-legged or feathered, and all equally good. The pure variety is large, with a round short body, broad breast and back, and closely feathered; when a year old, the male should weigh from 10 to 12 lbs., and the female from 8 to 9 lbs. They are little disposed to roam or do mischief in the garden; they are good layers, and their flesh is yellow, juicy, and of delicate flavor. The Cochin Chinas, considered by many the same as the Shanghai, are very large; the general color is a rich glossy brown or deep bay, with a black horse-shoe marking on the breast; the comb is moderate, serrated, and the wattles double. From their ability to double up the posterior half of the wing and to bring it forward between the body and the anterior half, they are sometimes called ostrich fowl. The flesh is white and delicate; the eggs are large, chocolate-colored, and of excellent flavor; and they are good layers. The Chinese fowls were imported from Canton about 25 years ago, and somewhat resemble the Cochin Chinas in size and color; they are good layers; the eggs are buff or nankeen color, and the flesh is good; they are hardy, peaceable, and easily raised; their wings are so short that they cannot fly over ordinary fences, and it is necessary that their perches should not be more than two feet from the ground, nor above each other. The Brahmapostras are either a gray variety of the Shanghai or a cross between the latter and the Chittagong; they are excellent layers, and their eggs are twice the size of a common hen's egg; a pair will weigh from 18 to 24 lbs.; crossed with the Dorking breed, it is very handsome. The Dorking breed, so called from the English

Dorking Cock.

town of Dorking in Surrey, are of large size and good shape, and if pure should have two toes behind instead of one; the silk fowl also is seen with five toes, and even a greater num-

ber of toes has been found, a peculiarity which by great care might become the characteristic of a breed. The color originally was pure white, but they are now generally seen speckled or mottled with black or gray. The flesh is white and delicate; they are good layers, and easily reared and fattened. This breed is supposed by Dickson to have originated from a cross of the Malay with the game fowl. The males weigh from 7 to 9 lbs., the females from 5 to 7 lbs.; when bred in and in for a long time, the comb becomes double. The black Poland, instead of a comb, has the head covered with feathers, which sometimes form a crest overhanging the eyes; there are also white, silver, or golden Polands, according to the general color; the first named is black, with a white topknot; all varieties with topknots are called Polands by the English. They are very ornamental, and excellent layers, but so little inclined to sit that their eggs are often put under other hens; they fatten quickly, and their flesh is considered by many as equal to

Poland Chickens.

that of the Dorkings. This breed is said to have been carried to Europe by the Spaniards from Santiago. The black Spanish fowl is a large breed, with high-colored comb and wattles, doubtless the result of high culture; the general color is black, and the feathers of the legs, thighs, and belly are velvety; the feet and legs are lead-colored; the distinguishing character is the silvery white cheek pieces; they are excellent for the table, and layers of the first order, and cross advantageously with the common fowl; from their wildness they are good for ranging over large farms; the male weighs from 4 to 6 lbs., the female from 3 to 4 lbs. The Fayal fowls are the same. The Bolton grays have the plumage silvery white, with minute and uniform pencillings of black; their forms are small, neat, and rounded, the comb double-rowed and sharp-pointed, the wattles large and round, and the ear lobes white; they are good layers, easily kept, hardy, and moderate eaters; they are also called Hamburgs, of which there are the varieties, creole, silver and gold spangled, and pencilled Hamburgs. The small race of bantams, so named from a town in Java, are distinguished by their plumed legs, a variation

caused by cultivation and high feeding; some have topknots, others have the legs naked; there is a dwarf variety, not larger than a pigeon; the Turkish cock seems to differ from the bantam only in the naked legs. Many extensive breeders are of opinion that the native yellow-legged fowl is as profitable as any foreign breed; of course they vary much, according to the mixture of varieties; they ought to lay from 150 to 250 eggs in a year, but probably, as generally kept, they do not average more than 30, and their average weight would not exceed $2\frac{1}{2}$ lbs.

COCKATOO, a name given to the parrots of the subfamily *cacatuina*, family *psittacidae*, from their peculiar call note or cry. The cockatoos have the bill large, of various lengths, broad at the base, with the culmen usually much arched to the tip, which is very acute; the wings generally rather long and pointed, the tail broad and mostly even, the tarsi short and robust and covered with small scales, and the toes unequal. They may be readily distinguished from the other parrots by their light color, and their graduated crest and even tail; some of the genera, however, have sombre colors, but none the gorgeous hues of the lories, macaws, and parakeets. Their robust legs and strong claws indicate the rasorial or scratching propensities of the group; and their powerful bills are able to break the stones of the hardest fruits. They are rather wild, and possess but little imitative power, seldom articulating anything more than "cockatoo."—The genus *cacatua* (Briss.), from which the subfamily is named, has the bill short and strong, hooked and acute; the wings long, and the tail short and even. About a dozen species are found in the forests of the Moluccas and Australia, some preferring high trees near rivers and swamps, others the open plains; they are shy and hard to approach, though their presence is easily known from a distance by the loud screams from their vast flocks; they feed on vegetable substances, seeds, nuts, tubers, and bulbous roots, which they dig up with their strong claws; they do much injury to trees by stripping off the bark of the smaller branches, cutting it into small pieces, but not using it for food; the eggs, usually two in number, are laid in the rotten portions of holes in trees, or in fissures of the rocks. This genus embraces some of the most beautiful species, of large size, of a white plumage tinged with rose color or sulphur yellow, and with large crests. Among the finest is the tricolor-crested cockatoo (*C. Leadbeateri*, Vigors), with a crest of scarlet, yellow, and white, of long acuminate feathers, with the tips directed forward, which the bird can open and shut like a fan; it is a native of Australia; the whole of the body is white, tinged with crimson on the neck, breast, sides, and under the tail and wings. The sulphur-crested cockatoo (*C. sulphurea*, Gmel.) resembles the last named, except that pale sulphur yellow takes the place of the red-

dish tints; it is a native of the Moluccas and other Indian islands; from its beauty, docility, and amusing habits, it is a favorite with bird fanciers. Other species living in the Moluccas

Tricolor-crested Cockatoo (*Cacatua Leadbeateri*).

are the *C. rosei-capilla* (Vieill.), *C. Moluccensis* (Gmel.), and *C. cristata* (Linn.); the red-crested cockatoo, *C. Philippinarum* (Gmel.), a native of the Philippine islands, is also a handsome species.—The genus *licmetis* (Wagler) differs from *cacatua* in having a bill much longer; it is peculiar to Australia, living in flocks on trees in the neighborhood of water; the food consists of bulbous roots, which they dig up from considerable depths in the earth; the notes are rather plaintive. Another genus peculiar to Australia is *calyptorhynchus* (Vig. and Horsf.), characterized by a very large and strong bill, broad at the base, and much higher than long; the lower mandible small, dilated, and strongly emarginated at the tip; the wings moderate, and the tail lengthened and rounded. They live in small flocks in woods near rivers, feeding on the fruit and bark of the *eucalyptus*, destroying more than they eat by cutting

Banksian Cockatoo (*Calyptorhynchus stellata*).

off the smaller branches and unripe fruit; their flight is heavy and noisy; they are very shy, and more fierce and wild than other parrots; the eggs, two or three in number, are

laid in the hollows of decayed trees. There are about a dozen species, of large size, and of dark colors. One of the finest species is the Banksian cockatoo (*C. stellata*, Wagler), called by the natives *geringore*; the plumage is generally greenish black, with a purple tinge on the back and wings; the bill is grayish white, the cheeks yellow, and the lateral feathers of the black tail vermilion in their central portion

Goliath or Great Black Cockatoo (*Microglossum aterrimum*).

with narrow bars of black. A larger species is Solander's cockatoo (*C. Temminckii*, Kuhl).—One of the largest of the parrot family is the Goliath, or great black cockatoo, belonging to the genus *microglossum* of Geoffroy, which is characterized by a very large bill, much curved to the long and acute tip, the lateral margins of the upper mandible bidentated, the lower mandible smaller, broad, and much emarginated on each side; the cheeks and front of the

Long-billed Cockatoo (*Nestor productus*).

throat denuded of feathers; they live in the forests of Papua, Ceram, and other eastern islands. This species (*M. aterrimum*, Gmel.) is of dark color, with a crest of grayish, long narrow feathers, which can be erected at will. The genus *nestor* of Wagler has the bill much lengthened, the wings long and pointed, and the tail moderate and even, with the shafts of the firm broad feathers pro-

longed beyond the webs. There are two species, living in New Zealand and Australia; they eat nuts, berries, and bulbous roots; in the morning and evening they are very noisy. The southern brown cockatoo (*N. australis*, Shaw) has the forehead and crown grayish white, slightly tinged with green; the ear coverts yellowish; the sides of the neck, breast, and abdomen dull red, the feathers margined with green; the back and wings brownish oil-green; the rump and vent deep red; the tail brownish green.

COCKATRICE, generally identified with the basilisk, a fabulous, serpent-like animal, which was believed to be produced from a hen's egg. The superstition prevailed among the ancients and during the middle ages. (See **BASILISK**.)

COCKBURN, Sir Alexander James Edmund, an English jurist, born in 1802. His father, Alexander Cockburn, was British minister in Colombia; his mother was a daughter of Viscount de Viguier of Santo Domingo; and he succeeded to the baronetcy on the death of his uncle, Sir William Cockburn, dean of York, in 1858. He graduated at Cambridge, was called to the bar in 1829, and went the western circuit. He was made a queen's counsel in 1841, and obtained a large share of the parliamentary practice that grew out of the railway mania of 1846. In 1847 he was returned to the house of commons from Southampton, and distinguished himself especially in 1850, when he made his celebrated defence of Lord Palmerston's foreign policy. In August, 1850, he was appointed solicitor general and knighted, and in March, 1851, attorney general, which office he held (with an interval from February to December, 1852) till November, 1856. In 1854 he was made recorder of Bristol, having previously been recorder of Southampton. He was a member of parliament for Southampton till November, 1856, when, on the death of Chief Justice Jervis, he was created chief justice of the court of common pleas, and in 1859 became chief justice of the court of queen's bench, succeeding Lord Campbell, who was made lord chancellor. His charge to the grand jury, April 10, 1867, in the case of Gen. Nelson and Lieut. Brand, prosecuted by the Jamaica defence committee, contains an elaborate exposition of martial law, and of its application in various periods of English history. In September, 1871, he was appointed the British arbitrator under the treaty of Washington for the settlement of the Alabama claims. Differing with his colleagues at the Geneva conference, he refused to sign the award that was finally made in favor of the United States, and prepared an elaborate dissenting opinion. His course at the conference has been the subject of much criticism, especially on the part of the Hon. Caleb Cushing in his "Treaty of Washington" (1873). This work analyzes his character and manners with great severity, but does not refer to his domestic relations, which have been often com-

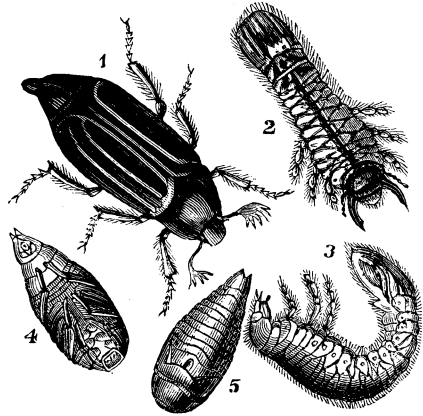

mented upon in England, particularly at the time when, relying upon his official distinction and influence, he insisted upon introducing his daughter, one of his numerous illegitimate children, into society in London. At the conclusion of the arbitration of Geneva it was proposed that he should be raised to the rank of baron; but the queen refused on account of his irregular domestic life, and he received only the grand cross of the order of the bath (1873).

COCKBURN, Catharine, an English authoress, born in London, Aug. 16, 1679, died May 11, 1749. She was the daughter of Capt. David Trotter, was converted from the Protestant to the Roman Catholic faith, and then reconverted, and in 1708 married Mr. Cockburn, a non-juring clergyman, who afterward took the oaths, and obtained the living of Long Horseley, Cumberland. She wrote "A Defence of Locke's Essay on the Human Understanding," and various essays, tragedies, comedies, and poems. Her works were published by Dr. Birch (2 vols., 1751).

COCKBURN, Sir George, an English admiral, born April 22, 1772, died Aug. 19, 1853. He served on the East India, home, and Mediterranean stations, and received the thanks of the house of commons for his operations against Martinique, by which that island came into the possession of Great Britain. He took a conspicuous part in the hostilities against the United States, particularly in the burning of the capitol and other public buildings at Washington in 1814, and in laying waste the banks of the Potomac and Chesapeake. Upon the close of the war he was employed to convey Napoleon to St. Helena. After his return to England he served repeatedly as member of the house of commons and as lord of the admiralty.

COCKBURN, Henry Thomas, lord, a Scottish jurist, born near Edinburgh, Oct. 26, 1779, died April 26, 1854. In 1800 he entered the faculty of advocates, and attached himself to the whig party, although his family connections belonged to the tories. His politics interfered with success in his profession, but in course of time he rose to eminence as an advocate. He brought himself into notice in 1818 by gratuitously defending several persons charged with treason. In 1828 he defended Helen McDougal, charged as an accomplice with Burke in the "Westport murders," and obtained her acquittal. Under the administration of Earl Grey, Jeffrey became attorney general and Cockburn solicitor general for Scotland. In 1834 he was raised to the bench as one of the lords of sessions, when he took the title of Lord Cockburn. Three years afterward he was appointed a lord commissioner of justiciary. He was an early contributor to the "Edinburgh Review," an article in which from his pen went far to produce a reform in the method of selecting juries. His literary fame rests on his "Life and Correspondence of Lord Jeffrey" (2 vols., 1852), and his posthumous "Memorials of his Times" (1856).

COCKCHAFER (*Melolontha vulgaris*, Fab.), a European insect, belonging to the lamellicorn family of the order *coleoptera* or beetles. The genus *Melolontha* was established by Fabricius, who first separated it from *scarabæus*. The body of the melolonthians is oblong oval, convex, and usually of a brownish color; the antennæ have nine or ten joints, five to seven of which are flattened into leaf-like pieces, which open like the leaves of a book; the jaws are horny and powerful for cutting and grinding the leaves and roots of plants; the thorax is nearly square; the wing cases leave uncovered the hinder extremity of the body; the legs are long, the first pair being armed externally with two or three teeth, which enables them readily to penetrate the ground; the claws of all are notched, which gives them a firm hold of the leaves. The habits and transformations of this species are well known, and will serve as a type for all the *Melolonthidæ*, which are all more or less hurtful to vegetation, as they feed

1. Cockchafer (*Melolontha vulgaris*). 2. Larva, back view. 3. Larva, side view. 4. Pupa, under side. 5. Pupa, upper side.

on plants from their birth to their death. Their duration in the perfect state is very short, each individual living about a week, and the species wholly disappearing in the course of a month. After the pairing of the sexes, the males perish, and the females dig a hole in the earth six inches deep, by means of their fore feet, in which the eggs are deposited to the number of 100 to 200; after this they return to the surface, and soon die. In two weeks little whitish grubs are hatched from these eggs, with six legs near the head, and strong jaws, which attach themselves to the tender roots, and commit often the most deplorable ravages; for three or four summers the larvæ live near the surface, sinking below the reach of frost as winter approaches, and remaining torpid till spring, when they change their skin, and ascend to the surface for food. When they have reached their full growth, they cease eating, and bury themselves about two feet deep, each

constructing a kind of lodge, smoothly lined by some glutinous silky substance thrown from the mouth; in this it is changed into a pupa or nymph, casting off its skin, displaying through the new envelope the parts of the perfect insect. In the month of February the cockchafer pierces this envelope, and three months afterward makes its appearance during the night in its final form. The ravages committed by these larvæ are often as extensive as those of the locust tribe. According to Kirby and Spence, they destroy whole acres of grass by devouring the roots, undermine the richest meadows, and eat the roots of wheat and other grains, and those of young trees; in England, Ireland, and France whole crops have been repeatedly destroyed by them. They are equally destructive in their perfect state. During the month of May they come forth from the ground, whence they have been called May bugs and May beetles. They are sometimes called also dor bugs. They pass the greater part of the day in a quiet state, attached to the branches and leaves of trees; as evening

Cockchafer.

approaches, they become active, buzzing about from tree to tree in search of food, and for the purpose of pairing. Their flight is dull, heavy, and irregular; they fall against objects in their way with a force which often brings them to the ground; they continue their flight till about midnight, and they frequently fly in at the window, being attracted and bewildered by the light of a lamp. In the "Philosophical Transactions" for 1697, it is stated that a few years before they were so numerous in Galway, Ireland, that they filled the hedges and trees, clinging to each other like swarms of bees, and when flying darkening the air like a cloud; in a short time all the foliage for miles around was consumed, and the trees in midsummer were as bare as in winter. Moullet, in his "History of Insects," says that in 1574 so many cockchafers were driven into the river Severn that the wheels of the mills were stopped. To check these ravages many methods have been employed, but nature has provided better means in the numerous animals and birds which feed upon them.—In America there are several melolonthians, whose ravages are nearly as great as those of the European

cockchafer. The most common is the May beetle (*phyllophaga quercina*, Knoch). This is of a chestnut-brown color, smooth, and finely covered with little impressed dots; each wing case has two or three slightly elevated longitudinal lines; the breast is clothed with a yellowish down; its length is about nine tenths of an inch. The perfect insect feeds on the leaves of trees, particularly on those of the cherry. It flies at night in May and June, and often enters houses, attracted by the light. The grub is a white worm with a brownish head, and when fully grown is nearly as thick as the little finger; it devours the roots of grass and other plants, in some cases completely undermining the turf; it is, in turn, greedily eaten by crows and domestic fowls, and the skunk is very fond of the full-grown insects. The best way to get rid of them is to shake the trees in the morning, when they do not attempt to fly, and collect them on cloths spread below; they should then be thrown into boiling water to kill them, when they may be given as food to swine. This insect is also called dor bug. There are several other species of melolonthians in America, varying in size from seven tenths to nine tenths of an inch, all nocturnal in their habits, and more or less injurious to gardens, nurseries, and orchards; they also devour the leaves of many forest trees.

COCKE, an E. county of Tennessee, bounded N. W. by the Nolichucky river; area, about 270 sq. m.; pop. in 1870, 12,458, of whom 1,274 were colored. It borders on North Carolina, and is traversed by French Broad and Big Pigeon rivers. The surface is mountainous and well wooded. Iron or Smoky mountain, on the S. E. border, is the principal range. It is traversed by the Cincinnati, Cumberland Gap, and Charleston railroad. The chief productions in 1870 were 79,007 bushels of wheat, 388,867 of Indian corn, 45,259 of oats, and 88,263 lbs. of butter. There were 1,994 horses, 2,830 milch cows, 4,866 other cattle, 9,730 sheep, and 19,297 swine. Capital, Newport.

COCKER, Edward, an English arithmetician, born about 1632, died about 1675. He was long supposed to be the author of the celebrated arithmetical work called by his name, but an attempt has been made to transfer its authorship to another. Cocker was an engraver as well as a teacher of writing and arithmetic. He is said to have published 14 books of exercises in penmanship, some of which were engraved on silver plates. He excelled as a calligrapher, and Evelyn asserts that his style rivalled that of the Italians.

COCKERELL, Charles Robert, an English architect, born in London, April 27, 1788, died in 1863. In 1811-'12 he excavated, with Baron Haller and others, the ruins of the temple of Jupiter in Ægina, and that of Apollo near Phigalia in Arcadia, the antiquities of the former being transferred to the British museum, and of the latter to the museum of

Munich. He also directed many excavations in Italy. In 1840 he became professor of architecture in London, acquiring eminence by his learning and ability, and was made a member of the principal academies of Europe. He was employed as architect by the bank of England, superintending its buildings for more than 20 years. He wrote extensively on archaeological subjects, and in 1860 published an account of his excavations.

COCKERILL, John, an English engineer, born in Lancashire, Aug. 3, 1790, died in Warsaw in 1840. He was the youngest son of an English machinist who had been employed in Belgium. John, with his brother James, also went to that country at an early age. After some preliminary experience, the former in 1816 established a machine shop at Seraing, which became one of the largest in Europe. In the height of his prosperity 2,000 workmen were employed there. This immense establishment belonged one half to the king of Holland, and one half to Cockerill; but at the revolution of 1830 the latter bought the king's share and remained sole proprietor. In 1839 he failed.

COCKERMOUTH, a market town and parliamentary borough of Cumberland, England, at the confluence of the Cocker and Derwent, 24 m. S. W. of Carlisle; pop. in 1871, 7,057. The ruins of a castle, founded toward the close of the 11th century, and razed by the parliamentary forces in 1648, are on a height on the left bank of the Cocker. The town has a free grammar school, some almshouses, and manufactures of linens, woollens, cottons, hats, and hosiery. Near it are extensive coal mines. The poet Wordsworth was born here.

COCKLE, the common name of the bivalve shells of the genus *cardium*, universally distributed, of which about 200 living species are known, besides about 270 fossil species belonging to the upper Silurian formation. The shell is of ventricose form with prominent umbones. The animal is furnished with a pow-

Cockle (*Cardium edule*).

erful foot adapted for burrowing in the sand; and by first bending and then suddenly straightening it, he can also use it to throw himself a considerable distance. *C. edule* lives in the

brackish water of the Thames as high as Gravesend, and is found in the Baltic, Black sea, and Caspian. On the coast of Devon a large prickly species (*C. aculeatum*) is eaten. The cockle of the New England coast is the *C. Islandicum*.

COCKNEY (probably from Lat. *coquina*, a kitchen, and related to the Fr. *Cocagne* and It. *Cuccagna*, an imaginary country of luxurious idleness), a nickname applied to a certain class of Londoners. It has been interpreted to mean a person so delicately nurtured as to be ignorant and incapable of labor, hardship, or any rudeness. The name occurs in verses as ancient as the reign of Henry II. When, during and prior to the reign of Henry VIII., the sages of the Middle Temple were accustomed to disport themselves on Childermas day, it was ordained that the king of the cockneys, with his marshal, butler, constable, and other officers, should be entertained with due service, in "honest manner and good order." The modern cockney mispronunciation consists in the abuse of the consonant *r* appended to words ending in a vowel, as Apollar, sofar, lor, for Apollo, sofa, law. The cockney school of literature is an appellation under which the wits of "Blackwood's Magazine," in its earlier numbers, assailed Leigh Hunt, Hazlitt, Keats, and some other young authors.

COCKROACH (*blatta*, Linn.), an insect belonging to the order of *orthoptera*, and to the group of runners or *cursoria*, having straight wings, and all the legs adapted for rapid motion. The genus *blatta* has five articulations to the tarsi; the wings are folded lengthwise; the wing covers are oval, horizontal on the top of the back, and overlapping on their inner edges; the body is oval and flattened; the antennæ are long and thread-like; the legs have small spines. Cockroaches are general feeders, eating indiscriminately both animal and vegetable substances. They undergo only a partial metamorphosis, their changes consisting in the increase and development of the wings and their covers, which exist as mere rudiments in the nymph state; in other respects the nymph and larva are like the perfect insect, walking and feeding in the same manner. They are nocturnal insects, and live both in the woods and in houses. They run with considerable swiftness. There are several species; those indigenous to this country are found exclusively in woods, under stones and leaves, while the common species, originally from Asia, infests dwelling houses, preferring warm and dark closets, ovens, and hearths, whence they issue at night in search of food. The oriental cockroach (*blatta orientalis*, Linn.) is spread extensively over Europe and America, especially in the maritime towns, being imported from the Levant in ships' cargoes. In many houses they are a perfect pest, devouring all kinds of animal and vegetable articles of food, and even destroying clothing, leather, cotton, and wool; on the approach of a light they escape with

considerable rapidity into their holes. Eat-ables which they cannot devour are often rendered unfit for use by the disagreeable smell communicated to them by their excrements.

Cockroach. 1. Male. 2. Female.

In old houses they swarm in great numbers, and the usual way to get rid of them is by poison. A mixture of red lead, Indian meal, and molasses, in a thick batter, placed at night near their haunts, will be eagerly eaten, and will soon exterminate them. Another more dangerous preparation is a mixture of a teaspoonful of powdered arsenic with a table-spoonful of mashed potato, which may be crumbled about the hearth at bedtime; this requires great caution in its use. Phosphorus mixed in a paste will kill them, and they are often driven away by borax, to which they have a great antipathy. The females lay one or two oval capsular bodies about as thick as one half their body, each containing 16 eggs. The cockroach is terrestrial in all its states, and equally omnivorous and voracious in all.

COCLES, Horatius, a hero of the old Roman law, who defended the Sublician bridge, in conjunction with Spurius Lartius and Titus Herminius, against the whole Etruscan army under Porsena, while the retreating Romans broke down the bridge behind them. When the work of destruction was nearly accomplished, Horatius sent back his two comrades, and as soon as the bridge was altogether destroyed, he himself plunged into the Tiber and swam across to the city in safety, amid showers of arrows from the enemy. Rome raised a statue to his honor in the comitium, and granted him as much land as he could plough around in one day.

COCOA, a preparation of the seeds of the tree called by Linnæus *theobroma cacao*. (See CACAO.) Several varieties of the tree have been since described, which produce beans, or seeds, varying somewhat in their size and properties. Their use is for the manufacture of chocolate. The article was unknown in Europe till it was introduced from Mexico in 1520 by the Spaniards; with them its preparation was long afterward kept secret. The seeds are prepared for use by roasting in the same way as coffee is roasted. When the

aroma is well developed, the beans are turned out into shallow wooden vessels and stirred till cool. Those which have been fermented now lose the shells readily, and split open into several lobes like split beans. The shells, amounting to about 12 per cent. of the whole weight, are separated by winnowing, and form an inferior quality of cocoa known as shells. The split seeds thus prepared may be used for food by long boiling; but for making chocolate they are ground, and mixed with other substances. (See CHOCOLATE.) Their average composition, according to Johnston, is nearly as follows: water, 5 per cent.; starch, gum, &c., 22; gluten, &c., 20; oil, 51; theobromine, 2. The theobromine is a white, crystallizable substance, similar to the theine in tea, but contains more nitrogen. The other constituents, as starch, gum, gluten, and the large proportion of fat, give to cocoa the variety of nutritive qualities possessed by milk, and like this it contains every ingredient necessary to the growth and sustenance of the body. A volatile aromatic oil and a bitter and an astringent principle are present, which affect the taste and qualities of the cocoa, though they are not detected in the analyses. The former is developed in the roasting, and is the cause of the aroma which is then exhaled. The fatty oil, called cocoa butter, resembles tallow in whiteness and consistence; it melts at 122° F., and in this condition may be separated by expressing it from the other ingredients. It has a mild and agreeable flavor, and is not apt to turn rancid. Neither tea nor coffee possesses the nutritive oily matter of cocoa, and of the gluten which is contained so largely in tea a considerable proportion remains in the leaves when the infusion is prepared. The shells contain but little theobromine and fat, a small portion of mucilage, no starch, but much vegetable tissue or lignine. Their infusion in boiling water is much used as a substitute for tea and coffee. Its taste is somewhat like that of chocolate, but weaker. The irregular-shaped, angular pieces into which the seeds separate by pressure after the shell is removed, are called nibs; they are the purest form in which cocoa can be purchased, being the kernel deprived of its husk and unadulterated. Their structure, exposed by the microscope, is seen to be that of minute rounded cells, which are filled with starch corpuscles and fatty matter. The fragments of the cells and the starch corpuscles may still be detected in the finely ground powder of the cocoa prepared for chocolate; and in this way the presence of undue proportions of the shells is exposed, as also of the numerous other matters used as adulterants. Cocoa should properly be the pure paste prepared by grinding the nibs between heated stones, and rolling into a flaky mass the oily product which flows out. This, when moulded and cooled, is called flake or rock cocoa; but the name of cocoa is often applied to compositions of the pure article with

other substances, which properly come under the designation of chocolate. The oil of the cocoa is extracted for certain cosmetic unguents and applications for the hair; after which the remainder of the flour is made into an inferior article called broma, which however is much liked by many persons who object to the richness of chocolate or cocoa.—The imports of cocoa, not including chocolate, into the United States in the year ending June 30, 1872, were 4,917,809 lbs., valued at \$600,640.

COCOANUT OIL, or **Cocoanut Butter**, the fixed oil of the fruit of *Cocos nucifera*, obtained either by expression or decoction. It is of a fine white color, of the consistence of lard at ordinary temperatures, becoming solid between 40° and 50° F., and liquid at 80°; of a bland taste and a peculiar and not disagreeable odor. It contains various solid and volatile acids. This oil, or fat, should not be confounded with cocoa or cacao butter (*oleum theobromæ*), which is obtained from the cacao nut. It is somewhat used in pharmacy as a substitute for lard, over which it has some advantages, and in medicine as a substitute for cod liver oil. The liquid part of the fat, or coco-oleine, has also been used for the same purposes.

COCOANUT TREE (*Cocos nucifera*, Linn.), one of the best known of the great family of palms, and perhaps also the most useful. There is a saying among eastern nations that its attributes would fill a book. Although a native of the tropics, and flourishing only on the seashore, it will grow as far north as Lucknow in India (lat. 26° 50' N.), and is planted far in the interior of that peninsula; but in the one case it does not bear fruit, in the other it is dwarfed and languishes. In conservatories the cocoanut seldom lives more than 10 or 12 years. The centres of the geographical range of this palm are the islands bordering on the Indian and central Pacific oceans. It is also found in the tropics of America, but is there considered rather an article of luxury than of necessity. The tree attains a height of from 60 to 100 ft., and a diameter of one or two feet. Its cylindrical, gently tapering trunk, usually somewhat inclined, from the constant winds of the tropics, is crowned by numerous feather-like leaves from 18 to 20 ft. long. The flowers appear on the axils of the leaves, and are enclosed in a thick tough spathe; when this first opens, the clusters of small, three-parted flowers have a beautiful milk-white appearance, although they soon become yellowish. The spathe opens always on the under side, and soon falls off, leaving a spicate spadix bearing the female flowers near the base. As in most palms, the blossom is beautiful from the great number of the florets rather than from any individual grace. In favorable places these clusters are produced every six weeks during the rainy season, and each one ripens from 5 to 15 nuts. Each tree thus has a succession of fruit, and may produce from 80 to 100 nuts a year. In planting the nut the three black spots on one

end are left uppermost. From one of these the stem rises, and the shell is soon split. Often the nut does not begin to germinate for six months, or even a year, after planting, while it is sometimes seen sprouting when lying on the ground, with its husk still green. Its growth is very slow for the first two years, and not until six or seven years old does it begin to bear, continuing until 70 years, or even longer. After the tree ceases to bear, the wood becomes very hard, and from its peculiar fibre is known as porcupine wood. Where it grows it is used for posts and rafters to houses, and the immature wood, which has a soft centre easily removed, is used for water pipes. The rootlets are astringent and are used for chewing. The leaves are usually 12 or 15 in number, and 5 or 6 are formed every year, the old ones dropping off, and leaving the horizontal scars that ornament the trunk. The new leaf is enclosed in a tough fibrous sheath, which is used as a strainer, or even for clothing; the

Cocoanut Palm.

pointed, solid leaf soon bursting through it, and by the elongation of its midrib becoming a pinnate leaf. When fresh the leaves are cooked and eaten as cabbage. The dry leaves are plaited together, and form the covering for the roofs and sides of bungalows. The base, with the midrib, serves as a paddle; the midrib as an arrow or spear; the lateral ribs, when stripped, make good brooms. The leaflets serve for paper, the writing being made with a sharp point, and cow dung is usually rubbed in to make the characters more distinct. The leaves are also used for fans, fences, thatch, bedding, fish nets, sieves, and hats. The smaller ribs are made into neat combs. The whole makes a good torch, and is also burned by the washerwomen for its potash. The flowers contain a most powerful astringent, and in Ceylon are used medicinally in various debilitating diseases. Before they burst from the spathe, the sap, or toddy, is obtained by bruising and sli-

ing the base or extremity. The quantity collected in this way varies, and always diminishes the yield of fruit. When fresh the toddy is delicious, and acts as a gentle aperient. Fermentation takes place in a few hours, and the liquor is then known as palm wine, which is a pleasant drink, and is much used by bakers for yeast. By distillation toddy yields 25 per cent. of arrack. By allowing the fermentation to proceed, a good vinegar is obtained; and by boiling the fresh toddy a tolerable sugar, or *jaggery*, can be made. Eight gallons of sweet toddy yield two gallons of a luscious liquid called *pervin* by the Cingalese; and the brown sugar obtained from this by further boiling is formed into round cakes, and eaten or exported. The husk of the coccanut is very fibrous, and contains considerable silica. Cut transversely, the halves of the nut make excellent scrubbing brushes for the decks of ships. The husk when dry is stripped off by means of a small stake fixed in the ground, and a man can strip 1,000 nuts a day; the husks are then soaked for several months in water to separate the fibres, and finally twisted into rope, or woven into mats, under the name of *coir*. The rope is very strong and light, does not rot when wet, and floats on the water. It is stronger and more elastic than hemp, and is preferred to hemp or chain for cables, as enabling a ship to ride easily at anchor in rough weather. Forty nuts usually yield six pounds of coir. The Polynesians twist and braid small cords of this fibre, which, as "sinnet," serves in the construction of houses and canoes, where Europeans would use nails. The shell of the nut within this husk is very hard when fully ripe, and takes a fine polish; burnt, it forms good lampblack, and as charcoal is in demand as a dentifrice. When the nut is still green it contains from one to two pints of a rich clear liquid, always cool when first gathered from the tree, and the shell is lined with a gelatinous soft mass, which is eaten either alone or flavored with various juices. An analysis of this liquid shows in 1,000 parts:

Water	900.88
Sugar	4.43
Gum	17.67
Extractive matters (oil)	28.29
Salts soluble in alcohol	5.44
Salts insoluble in alcohol	6.29

When taken to excess, it produces strangury, but people often drink nothing else for weeks without bad effects. When the nut is gathered with the stem attached, it may be kept fresh at sea for several weeks, and the water is considered a good remedy for seasickness. It is also used with lime in making *chunnam*, a hard plaster, and in various processes of cooking. As the nut ripens, the albumen is deposited in a thick lining in the shell, and the liquid becomes insipid. The albumen in this form may be eaten, and is cooked in various ways, always forming an important ingredient of genuine curries and mulligatawnies. It contains much oil, and the Polynesians chew it up and rub it into their hair as a

pomatum. The oil is perhaps one of the most valuable products. The Micronesians break up the ripe nuts and expose the meat to the heat of the sun in covered troughs, keeping the mass constantly wet. Fermentation takes place, and the oil drops out into receivers. The East Indian process is almost as rude, the broken nuts being ground in a wooden or stone mill of primitive construction. The product varies in quantity as well as in quality; 10 nuts sometimes produce a quart of oil, and at other times 30 yield only three pints. In some places the ground nuts are pressed or even boiled, but the oil thus obtained is inferior. The best oil is used for cooking purposes, or to anoint the body, a most grateful process in a hot climate, and the inferior sorts for illumination. Large quantities are imported into the United States and England for the manufacture of candles and soap. The coccanut is an example of the palms that have two of the three ovules regularly abortive, the third occupying the whole inner surface of the nut, and in germination sending the radicle through the only one of the three apertures in the shell which remains soft.

COCO-MARICOPAS, or *Maricopas*, a tribe of semi-civilized Indians, living upon the river Gila, New Mexico, about 150 m. above its mouth. They occupy a portion of the rich alluvial valley found there, in common with another tribe known as the Pimos, which holds the same rank in civilization. The valley is there about 15 m. in length, and from 2 to 4 m. in width, nearly the whole of which is occupied by the villages and cultivated fields of these two tribes. The Pimos occupy the eastern portion. There is no dividing line between them, nor anything to distinguish the villages of one from those of the other. Their joint reservation, as established by congress, on both sides of the Gila, is about 25 m. long and 4 m. wide, extending from Maricopa Wells to below Sacaton. The whole of this plain is intersected by irrigating canals from the Gila, by which they are enabled to control the water, and thereby raise luxuriant crops. The villages consist of groups of from 20 to 50 habitations, surrounded by gardens and cultivated fields, the latter fenced with crooked stakes wattled with brush. Their houses are built with stakes, poles, corn husks, and straw. These habitations are from 5 to 7 ft. in height, and in diameter from 15 to 25 ft. There is usually a bower or shed attached to each wigwam, open on all sides, beneath which the occupants are generally seen engaged in their household duties, only resorting to their better protected abodes in cool or rainy weather. Besides the dwelling places, each family is provided with a storehouse or granary, better built than the former. These Indians possess horses, mules, and horned cattle. When ploughing is resorted to, oxen only are used; but they prefer to use the hoe for turning up the light soil. With this

simple instrument and a long-handled spade, they are able to cultivate as much ground as they require. The men generally plant and gather the crops. The food of these people is chiefly bread, made both of the flour of wheat and maize, and vegetables. Little meat is used. But that which elevates these tribes above most other aborigines is their knowledge of the art of spinning and weaving, an art known to the semi-civilized tribes of New Mexico before the arrival of the Spaniards. Cotton of a superior quality is raised by them, which they spin and weave into blankets of various textures and sizes, a heavy cloth used by the women to wrap around their loins, and an article from three to four inches wide, used as a band for the head or a girdle for the waist. The implements used for spinning and weaving are of the most primitive character. Their other manufactures are baskets and pottery. The basket work is remarkably well made of willow twigs, of various shapes, and used for different purposes. Their pottery is either red or dark brown, some of it quite fine, though not equal to that made by the ancient tribes, fragments of which cover the adjacent grounds. It consists of vases and cups holding from half a pint to six or eight gallons, jars with small apertures, basins of every size, and oblong vessels used as dippers. The ornaments on their pottery and their cotton manufactures closely resemble those on the pottery found among the ancient ruins and sites of ancient towns throughout New Mexico. They resemble, too, the ornaments of the Pueblo or semi-civilized Indians of the country, which leads to the inference that the Coco-maricopas, the Pimos, and the Pueblo Indians generally, are descendants from the ancient people who have left so many remarkable works in the great basin of the Colorado. The dress of the women is simply a cotton blanket or cloth wrapped around their loins. Sandals of raw hide are worn on the feet. Nothing is worn on the head, nor is the hair ever tied up. In front it is cut off square across the eyebrows; the rest is suffered to hang loosely over the ears, neck, and half way down the back. It is a universal custom among the women, when they arrive at maturity, to draw two lines with some blue-colored dye from each corner of the mouth to the chin. This is pricked in with a pointed instrument, and remains through life. The men generally go naked, except the breech cloth. In cool weather they throw one of their native blankets over their shoulders. Much pains is taken in decorating the head. They wear their hair long, never cutting it except across the eyebrows. When loosed, it reaches to their knees; but usually it is clubbed up in a large mass on their backs. This people restrict themselves to a single wife. They believe in the existence of a great spirit and in an existence after death; that their souls go to the banks of the Colorado, their ancient dwelling

place, where they are metamorphosed into various animals and birds; they believe, too, that the feuds which have existed on earth between them and other tribes will continue after death. The Coco-maricopas lived originally on the Colorado, but were found about 50 miles beyond their present location early in the last century. In 1775 Father Font found them on the river Salinas, 10 or 20 miles from the Pimos. Subsequently they removed for protection to the valley occupied by the Pimos, with whom they live on terms of the greatest harmony, and whose customs they have adopted. Their languages are totally different. The language of the Coco-maricopas has a close affinity with that of the Yumas of the Colorado, and Comeyas of California. The Maricopas numbered in 1870 only 382 in two villages, and are rapidly disappearing from their contact with the whites.

COCOON, an oblong ball or case, in which the silkworm involves itself, formed from the very fine filaments from which silk thread is made. The term is also applied to the envelope of other larvæ during their pupa state. (See BUTTERFLY, CATERPILLAR, and SILKWORM.)

COCOPAS, a tribe of Indians allied in language to the Yumas, living upon the Colorado river of California, between the mouth of the Gila and gulf of California. They number less than 500 souls, and live by cultivating the soil. In the report of Don José Cortes to the king of Spain, made in 1799, this tribe is mentioned as then embracing 3,000 souls.

COCYTUS, in antiquity, a river in Epirus deriving its brackish water from the melted snow of Mount Pindus, and emptying, after a course underground, into the Acherusian lake.—Also a river of the infernal regions, a tributary of the Styx, emptying with the Pyriphlegethon into the Acheron.

COD (*Morrhua*, Cuv.), a genus of soft-rayed fishes belonging to the family of *gadidae*, characterized by an elongated, smooth body, compressed toward the tail; three dorsal fins; ventral fins pointed; abdominal line with two fins behind the vent; the lower jaw with one barbule on the chin. There are eight species

Cod (*Morrhua Americana*).

described as occurring in North America. The American cod (*M. Americana*, Storer) is the common species of the New England coast, ranging from New York to the St. Lawrence river.

The color of the back in the living fish is a light olive-green, becoming pale ash in dead specimens, covered with numerous reddish or yellowish spots to a short distance below the lateral line; beneath it is dusky white. The color of this species, however, is variable; some are of a greenish brown hue with few spots; others, called rock cod, are of a bright red color; some are very dark, others very light and greenish. This species grows to a great size; the largest specimen alluded to by Dr. Storer, in his "Report on the Fisheries of Massachusetts," weighed 107 lbs.; the average weight is about 8 lbs.—The common or bank cod (*M. vulgaris*, Linn.), well known the world over as an article of food, is taken on the Grand bank, in the deep water off the coast of Newfoundland, Nova Scotia, and Labrador, and indeed is met with from the coast of Maine to lat. 67° N. It is a thick, heavy fish, sometimes attaining a weight of 90 lbs. The color varies considerably, but is generally a greenish brown, fading into ash in the dead fish, with numerous reddish yellow spots; the belly is silvery opaque white, the fins pale green, and the lateral line dead white.—A third species, the tomcod (*M. tomcodus*, Mitchill), is found along the American coast from New York northwardly to Nova Scotia and New Brunswick, at all seasons of the year; it frequently ascends rivers. It varies in length from 6 to 12 inches. The colors also vary exceedingly, being generally brownish above with spots of a darker hue, and lighter beneath. The tomcod is caught from wharves and bridges by almost any bait; in the winter large numbers are taken in dip nets at the mouths of rivers. The cod is abundant along the N. Pacific coast, particularly in the region of Alaska. It also swarms along the W. and N. shores of Norway, in the Baltic, off the Orkney and Western islands, and on the S. and W. coasts of Iceland. It is an exceedingly voracious fish, devouring indiscriminately everything in its way in the shape of small fish, crustacea, and marine worms and shell fish. Indeed, the cod is the great collector of deep-sea specimens, otherwise unattainable; and many are the specimens of rare and new shells which naturalists have obtained from its capacious stomach.—The cod is very prolific. A cod roe has more than once been found to be half the gross weight of the fish; and specimens of the female have been caught with upward of 8,000,000 eggs. Were all these to come to maturity, a pair of cod would in a few years fill the ocean; but only a portion of the eggs are fertilized, and only a small percentage of the fish ever arrives at maturity. The cod spawns in mid-winter, but its habits have not been observed with sufficient accuracy to determine when it becomes reproductive. The best authorities hold that it is an animal of slow growth, and that it is at least three years old before it is able to propagate. A question of great interest is, whether it is possible by over-fishing to ex-

haust the cod fisheries either partially or entirely? As yet no serious impression appears to have been made on the bank fishery, after 3½ centuries of ceaseless fishing. The same, however, cannot be asserted in regard to the shore fishery, at least at certain points; and the frequent complaints of late years of the scarcity of fish in certain bays, as compared with former times, and the numerous failures in the summer fishery, awaken the suspicion that the perpetual drafts, year after year, without any interval for recruiting, have seriously reduced the number of codfish in certain localities. The scarcity of cod in Conception and Trinity bays, and other places, of late years, as compared with former times, is generally allowed; and the bulk of the population of these bays now proceed to Labrador for their summer fishing. The theory of the migration of fish, once a general notion, is now known to be a popular delusion, and has been abandoned by all scientific naturalists. The migratory instinct in fish is ascertained to be very limited, merely leading them to move about a little from their feeding ground to their spawning ground—from deep to shallow water. In fact there are in the world of waters great fish colonies, as there are great seats of population on land; and these colonies are stationary, having comparatively but a limited range of water in which to live and die. All around the shores of Newfoundland are numerous banks, or submarine elevations, of greater or less extent, which constitute the feeding and breeding grounds of the cod; and each of these has its own fish colony that live and die within a limited range of their own habitat. They do not intermingle with other colonies or invade their domains. This is proved by the well known fact that the cod of different localities are marked by distinctive features and qualities; the cod, for example, of Placentia bay being quite distinguishable from that taken in Bonavista bay. So, too, the vast fish colonies of the great banks, at a considerable distance from the shores, differ from shore fish, being larger and finer, and, except a few adventurous individuals that roam from home, are not found at any distance from the place of their birth. The bank and shore fish keep to their respective homes. If heavy drafts are made on the smaller colonies around the shores and in the bays, in the course of years these will become seriously diminished in numbers. Facts seem to indicate that this is the case in many localities at present. The average catch of codfish now is not greater than it was 50 years ago, though many thousand more hands are now engaged in fishing.—Cod fishing is an important branch of industry, the Roman Catholic countries of Europe, South America, and the West Indies furnishing a ready market. The great resort of the American, Nova Scotian, and French fishermen is the Grand bank of Newfoundland, and the banks E. and S. E. of Nova Scotia, which

may be distinguished as the western banks, the westernmost being known specifically as the Western bank. The Miquelon islands and St. Pierre, off the S. coast of Newfoundland, belonging to France, are the rendezvous of the vessels of that nation. Of the United States, Massachusetts is the most extensively engaged in the fishery, the principal ports being those on Cape Cod, with Plymouth, Kingston, Marblehead, Beverly, and Gloucester. Maine comes next by a long interval, the principal places engaged being Portland, Wiscasset, Boothbay, Waldoborough, Belfast, Castine (employing more vessels than any other town in the state), and the ports about Frenchman's bay. Gloucester is the great fishing port of the country. A few vessels from this town make winter trips, from three to five weeks in length, to the Western bank, the number increasing after the beginning of February. In this month also fishing commences on Georges bank (S. E. of Massachusetts), the trips averaging three or four weeks. The Georges fleet is largest in March, begins to decrease in April, and almost disappears in June. As the weather grows milder and the Georges fleet diminishes, the Gloucester vessels commence their trips to the fishing grounds off Cape Sable and Cape North, in the gulf of St. Lawrence, and on the Western and Grand banks. The trips to the Grand bank rarely exceed 12 weeks in length, those to the western banks 9 weeks. The Cape Cod vessels do not engage in winter fishing. About five sixths of them sail for the banks during the first half of April, and make two trips, or "fares," arriving on their first fare early in June, sailing again the last of that month, and arriving on their second fare the latter part of August or first of September. The remaining sixth sail about the middle of May, and make but one fare, arriving in August or September. Provincetown vessels, however, all make one long trip to the Grand bank, sailing in April, and sometimes prolonging their stay until October. Marblehead and Beverly vessels that make two fares arrive on their first fare in July or August, and on their last in November. The vessels employed are schooners of from 45 to 100 tons, averaging 60 or 70. The number of the crew varies from 9 to 14, sometimes exceeding the latter number. The bank fishermen all use dories, or flat-bottomed boats, which are sent out, usually twice a day, a short distance from the vessel, which lies at anchor on the fishing ground. The larger proportion (perhaps three fourths) of the Massachusetts vessels use trawls, which are set and hauled periodically. The trawl consists of a long line anchored and buoyed at each end, with hooks, generally several hundred in number, adjusted at intervals. The trawlers use dories about 15 ft. in length, usually carrying one for every two men. The fishermen that use hand lines carry a dory 12½ ft. long for each man except the cook, and in the largest vessels the "skipper," as

the captain is called. Owing to the strong tide on Georges bank, the fishermen do not use dories there, but fish directly from the vessel. The Maine vessels carry larger crews than those from Massachusetts, and use hand lines. The trawlers use fresh bait, herring, mackerel, or squid; the hand-liners use salted clams for the first of the season, but afterward usually obtain squid. The fish when brought aboard the vessel are dressed and salted in the hold. Upon arrival home they are taken out, washed, and dried on flakes, or platforms of wickerwork, on the shore. The process of dressing them is reduced to system, and is performed with great rapidity. The throater, usually a boy, cuts the throat and rips them open; the header removes the entrails and the head; the splitter splits the fish, removing a portion of the backbone; while the salter piles them in tiers and sprinkles them with salt. There are two principal methods of employing the crew. Under one system, a portion of them, called sharesmen, take the risk of the voyage and hire the rest of the men. These shares number from one to five, three or four being the usual number. There may be whole shares or parts of shares, the latter occurring when a portion of the compensation is at the risk of the voyage and the rest is received in wages. The hired men receive from \$150 to \$250 for one fare, and from \$200 to \$300 for two fares. The cook is usually paid from \$50 to \$60 a month. In settling the voyage, as it is termed, the skipper takes a small proportion of the gross stock, generally 3 per cent. The "great general supplies," consisting of salt, bait, dories, fishing tackle, &c., are then deducted; the owners of the vessel next draw one fourth; one eighth of what remains is paid for curing the fish; the provisions are then paid for; and finally the wages of the hired men are deducted. Whatever is still left is divided among the sharesmen, the skipper drawing a share in addition to his percentage. With fair success, the sharesmen will draw about 45 per cent. of the gross proceeds, though the proportion varies of course according to circumstances, and they sometimes fail to pay their expenses. This system is in use on Cape Cod, and in Plymouth, Marblehead, and Beverly. By the other method the owners equip the vessel, and buy the fish green upon her arrival, at the market price for the time being. The crew receive half the proceeds, paying only half of the bait bill and of the cook's wages, having left about 45 per cent. net, which in vessels that use trawls is generally divided equally, but in the case of those that use hand lines is commonly shared among the crew according to their respective catch, or on the "own hook lay." This system is in vogue in Gloucester. The Maine fishermen use the same method, but do not sell their fish until cured. The Nova Scotia vessels mostly use trawls. The sharesmen, six or eight in number, hire the boys and ordinary fishermen, and

divide the proceeds according to the system last described. The French fishermen leave home with their salt, provisions, &c., in the latter part of winter or early spring, and come directly to St. Pierre, where they equip for fishing, generally making two or three trips to the banks from that port. Their fishing season extends from April to October. Their vessels range in size from barks of 300 tons to shallops of 20 tons. They all use trawls equipped with 6,000 or 8,000 hooks, which are set at night and hauled in the forenoon, and boats of sufficient size to weather any ordinary gale, each manned with seven men. They procure their bait at St. Pierre, using salted herring for the first fare and capelin for the other two. A portion of the fish is cured at St. Pierre, but the greater part is taken green to France, and there cured. Some vessels from Cape Cod are employed in fishing on the shoals that lie along the coast from Nantucket N. to the extremity of the cape. They make short trips, returning every two or three weeks to land their fish and procure fresh bait. Many boats are also employed from the shore. Large quantities of cod are brought in fresh to the markets of New York, Boston, and other cities, by the numerous small vessels engaged in market fishing. Cod fishing from Cape Breton and Newfoundland is pursued almost exclusively in boats from the shore. The smallest of the fish, instead of being dried, are sometimes preserved in pickle and sold by the barrel. The dried fish are sold by the quintal of 112 lbs. Codfish are sometimes cured by being kept in a pile for two or three months after salting, in a dark room, covered with salt grass or the like, after which they are opened, and again piled in a compact mass for about the same length of time. They are then known as dunfish, from their color, and are highly esteemed. Of the fish caught on the banks with hand lines previous to the first of July, it takes about 50 to make a quintal of dried fish; after that date 30 will yield a quintal. Fish caught with trawls average 36 to the quintal throughout the year. The livers are preserved, and the oil obtained from them is valuable as a medicine in pulmonary complaints. The tongues

and sounds are also frequently preserved in pickle. From the sounds, prepared and dried, isinglass is obtained.—According to the United States census of 1870, the product of the American fishery for that year was 559,982 quintals of cod, of which 28,484 quintals belonged to Connecticut, 79,373 to Maine, 451,125 to Massachusetts, and 1,000 to Washington territory. In that year 94,750 quintals were caught in Alaskan waters, and brought mostly into San Francisco. For the year ending June 30, 1871, there were entered in the various customs districts 658,756 quintals of cured cod (product of domestic fishery), valued at \$3,747,535; oil, other than whale (chiefly cod-liver), 729,558 gallons, valued at \$420,146. For the year ending June 30, 1872, there were entered 727,487 quintals, valued at \$3,194,286, and 1,437,343 gallons of oil, valued at \$508,402. These figures do not include large quantities of cod brought in by coasters, fishing smacks, &c., not making entry at the custom houses, of which there are no trustworthy statistics. The number of men in the United States employed in the cod fishery is from 12,000 to 15,000. The government, regarding the cod fishery as a nursery of seamen for the navy, by the acts of 1813 and 1819, offered a certain sum per ton as bounty to vessels engaged in the business. The payment of bounties was discontinued by the act of July 28, 1866, to which time about \$16,000,000 had been expended; but the duties on imported salt used in curing fish are remitted. The product of the British American fishery for 1869 was as follows: province of Quebec, 136,774 quintals of cod, valued at \$410,322; 103,018 gallons of oil, worth \$51,509; and 287 barrels of tongues and sounds, value \$2,009; New Brunswick, 17,924 quintals of cured cod; Nova Scotia, 355,638 quintals; Prince Edward island, value of cod, &c., obtained, \$39,893; Newfoundland, exports of cod, 1,204,086 quintals, valued at \$5,514,040; 1,224,468 gallons of cod-liver oil, value \$978,425; 964 barrels of cod roes, worth \$3,615. The number of men in Canada and Newfoundland engaged in cod fishing is from 40,000 to 50,000. The product of the French fishery from 1863 to 1868 was as follows:

RECEIPTS AT THE FRENCH PORTS, IN QUINTALS.

PRODUCTS.	1863.	1864.	1865.	1866.	1867.	1868.
Cod, green.....	416,880	428,644	423,310	516,220	535,770	539,870

Oil, crude.....	2,746	6,332	3,834	2,465	2,384	2,393
Roes.....	4,496	3,750	2,402	5,406	6,452	7,366
Other products (tongues, sounds, &c.).....	13,126	16,458	18,080	19,114	22,000	21,738

Of the cod obtained in 1868, all but about 3,000 quintals was from the Newfoundland and Iceland fisheries known as *la grande pêche*. The value of the green and dry fish in 1868 was \$3,331,917; of the oil, \$504,647. A quintal of oil is equivalent to about 12 gallons. The French government has spent large sums

by way of bounty for the encouragement of cod fishing, a premium being paid as well upon the export of the fish as upon the vessels engaged in the business. The following table exhibits the number of vessels and men engaged in the fishery, the exports of cod, and the bounty paid, from 1863 to 1868:

YEARS.	Vessels.	Men.	Bounty.	EXPORTS.			
				FROM PLACES OF FISHERY.		FROM FRANCE.	
				Quintals.	Bounty.	Quintals.	Bounty.
1863.....	560	13,753	\$133,890	142,991	\$279,722	61,391	\$92,060
1864.....	467	12,774	122,064	144,004	280,629	58,673	88,358
1865.....	573	12,434	120,087	166,095	324,224	54,913	77,367
1866.....	583	12,651	120,498	174,893	347,192	53,045	72,331
1867.....	603	12,178	115,670	145,876	288,829	57,992	89,651
1868.....	654	13,164	124,928	111,795	222,310	26,368	38,308

The aggregate tonnage in 1868 was about 80,000. The principal fishing ports are Dunkirk, Bordeaux, Cette, La Rochelle, Marseilles, Granville, St. Servan, St. Malo, Boulogne, Paimpol, and Gravelines.—The cod fishery of the British islands is important, and is pursued chiefly in the vicinity of the Shetlands and Orkneys, off the shores of Essex, Suffolk, Norfolk, and Lincoln, and around the Dogger bank. The catch of the English coast is mostly taken fresh to the London market. The returns are imperfect, but, so far as reported to the officers of the fishery board, the product of cured cod, ling, and hake in 1870 for Scotland amounted to the sum of 145,289 quintals of dried and 9,945 barrels of pickled fish. In 1870, 277 vessels were employed in cod fishing in Belgium, and obtained 30,604 quintals; the product for 1868 was 53,782 quintals. The most important European fisheries are those of Iceland and Norway. In Iceland the most productive cod fishing commences in February or March, and continues till May or June. In that island and Faroe from 75 to 100 deck boats and from 4,000 to 5,000 open boats, manned by 10,000 to 15,000 men, are employed. The annual product is about 100,000 quintals, of which 20,000 go to Denmark, 50,000 to Spain, Italy, &c., and the remainder is consumed by the islanders. In 1862, an abundant year, 59,123 quintals of "clipfish" (dried salted cod), and 6,525 of "stockfish" (dried unsalted cod), 6,557 barrels of liver oil, and 1,489 of roes were exported from Iceland; in 1865 the exports were only 22,036 quintals of clipfish and 313 of stockfish; in 1869, 46,819 quintals of clipfish, 3,954 of stockfish, 977 barrels of roes, and 7,744 of liver oil. The Norwegian cod fishery is carried on along the whole W. and N. shore of the country, particularly near the Loffoden islands, and commences in December; the best months are January and February. In 1866, 5,723 boats and 25,756 men were employed. The exports for 1865 were 490,344 quintals of clipfish, 332,398 of stockfish, 33,771 barrels of cod, 37,941 of roes, and 1,896,346 gallons of liver oil. The roes are principally used as bait for sardines. Besides the exports enumerated, it is estimated that from 200,000 to 300,000 quintals are annually bartered to the Russian traders of the White sea. In 1871, 18,500,000 cod were caught in the Loffoden fish-

ery, yielding 428,214 quintals of fish, 25,000 barrels of roes, and 31,000 of oil. The other principal fishery, that of Finmark, produced 12,500,000 cod. The exports were valued at about \$6,000,000. (See FISHERIES.)

CODDINGTON, William, founder of the colony of Rhode Island, born in Lincolnshire, England, in 1601, died Nov. 1, 1678. He arrived by the ship *Arabella* at Salem in 1630, as one of the magistrates of Massachusetts appointed by the crown. For some years he exercised his judicial functions, traded as a merchant in Boston, and accumulated considerable real estate at Braintree. In 1636, when Winthrop superseded Vane as governor, Coddington's name was dropped from the roll, but the freemen on the following day testified their approval of his course by sending him and Vane as their deputies to the court. When Mrs. Hutchinson was tried, during the Antinomian controversy, Coddington undertook her defence against Winthrop and his party. He also opposed the proceedings in the case of Wheelwright and others, but unsuccessfully. Becoming wearied of opposition, he removed with 18 others (April 26, 1638) to the island of Aquidneck, now Rhode Island, having drawn up and signed an agreement to found a colony which should be "judged and guided by the absolute laws of Christ." This being found too vague for actual requirements, Coddington was elected judge, with a council of three elders, who were enjoined by a vote of the freemen to be guided by God's laws. This arrangement was further modified, March 12, 1640, by the election of Coddington as governor, with a lieutenant governor and four assistants. He continued in office seven years, until a charter was obtained and the island incorporated with the Providence plantations. In 1648 he was again offered the governorship, but declined it in consequence of a suit he was engaged in respecting lands. Having made a voyage to England in 1651, he returned with a commission as governor of Aquidneck island, separate from the rest of the colony; but the people being alarmed at the attempt to deprive them of the nomination of their rulers, he resigned. From this time he withdrew from public affairs till 1674-'5, when he once more accepted the governorship. Coddington, after his settlement in Rhode Island, adopted the tenets of the Quakers.
